Accurately weigh ca 15 g sample into small, g-s flask, and add 10 mL phenylhydrazine soln. Let stand 30 min at room temp. and titr. with 0.5*N* HCl, using Me or Et orange indicator. Similarly titr. 10 mL phenylhydrazine soln. Difference in mL 0.5*N* acid used in these 2 titrns  $\times 0.076$  = wt citral in sample. If end point is difficult to detect, titr. until soln is distinctly acid, transfer to separator, and drain alc. portion. Wash oil with H<sub>2</sub>O, adding washings to alc. soln, back-titr. with 0.5*N* alkali, and make necessary corrections.

**Kirsten Modification of the Kleber Method (32)**

(For lemon oil)

**19.088****Reagents**

(a) *p*-Toluenesulfonic acid.—0.5*N*. Dissolve 95 g *p*-toluenesulfonic acid ( $\text{CH}_3\text{C}_6\text{H}_4\text{SO}_3\text{H}\cdot\text{H}_2\text{O}$ ) in absolute alcohol and dil. to 1 L with absolute alcohol. Mix thoroly and filter. Stdze against 0.5*N* NaOH, using Me red.

(b) *Methyl yellow indicator*.—Dissolve 0.1 g *p*-dimethylaminoazobenzene in 100 mL absolute alcohol. (Caution: See 51.085.)

**19.089****Determination**

Accurately weigh ca 15 g sample into 125 mL g-s flask and pipet in 10 mL phenylhydrazine soln, 19.086. Let stand 30 min at room temp. and add 25 mL benzene. Titr. with 0.5*N* *p*-toluenesulfonic acid, using 0.2 mL Me yellow. Similarly titr. 10 mL phenylhydrazine soln. Difference in mL 0.5*N* acid used in 2 titrns  $\times 0.076$  = g citral in sample.

**Hydroxylamine Method (30)**

(For lemon oil)

**19.090****Reagents**

(a) *Bromophenol blue indicator*.—Dissolve 0.1 g bromophenol blue in 5 mL 0.05*N* NaOH and dil. to 100 mL with 60% alcohol.

(b) *Ethyl orange indicator*.—Dissolve 0.05 g Et orange in 60% alcohol and dil. to 50 mL.

(c) *Potassium hydroxide std soln*.—0.5*N*. Dissolve 28.06 g KOH in 60% alcohol and dil. to 1 L with same solv. Stdze against std HCl.

(d) *Hydroxylamine soln*.—Dissolve 7.0 g  $\text{H}_2\text{NOH}\cdot\text{HCl}$  in 175 mL 60% alcohol. Add either: (1) 0.3 mL bromophenol blue indicator and enough 0.5*N* KOH to give permanent blue soln, or (2) 0.3 mL Et orange and enough 0.5*N* KOH to give permanent yellow soln. In either case dil. resulting soln to 200 mL with 60% alcohol.

**19.091****Determination**

Weigh, to nearest 10 mg, ca 10 g sample into g-s 50 mL graduate and add 7 mL hydroxylamine soln and 0.1 mL indicator. Shake and neutze liberated acid with 0.5*N* KOH to permanent full alk. color of indicator used. Continue shaking and neutzg until permanent alk. color remains in lower layer after shaking mixt. vigorously 2 min and letting sep. (Reaction is complete in ca 15 min.) 1 mL 0.5*N* KOH = 0.0761 g citral.

This titrn approximates citral in the oil. Repeat detn as above, using as color std for end point titrd liq. of first detn, and as vol.  $\text{H}_2\text{NOH}\cdot\text{HCl}$  soln 1–2 mL more than vol. 0.5*N* KOH used in first detn.

**Esters (32)—Official Final Action**

(For lemon oil)

**19.092****Apparatus**

*Expeller*.—Prep. rubber stopper with glass inlet and outlet tubes similar to wash bottle. Adjust outlet tube to just reach bottom of centrf. bottle and place soda-lime tube between inlet tube and source of air.

**19.093****Reagents**

(a) *Aldehyde-free isoamyl alcohol*.—Reflux ca 1 L reagent grade isoamyl alcohol over 35–40 g KOH 60–70 min. Distil in

all-glass app., reject first 25 mL distillate, and collect next 850 mL. Store at ca 5°.

(b) *Sodium chloride soln*.—Dissolve 160 g NaCl in 500 mL  $\text{H}_2\text{O}$ .

(c) *Carbon dioxide-free water*.—Use freshly boiled and cooled  $\text{H}_2\text{O}$  thruout detn.

**19.094****Determination**

Weigh 5 mL oil in beaker or bottle and transfer to 125 mL separator, using 25 mL alcohol to complete transfer. Add 1 mL 50%  $\text{H}_2\text{NOH}\cdot\text{HCl}$  soln and few drops phthln, and mix. Add, from buret or graduated pipet, enough 4% KOH in 80% alcohol to make soln just pink and add drop or so excess. Add 1 drop 20%  $\text{H}_2\text{NOH}\cdot\text{HCl}$  soln and shake; pink should be discharged. Add 25 mL isoamyl alcohol and shake. Add 50 mL NaCl soln, shake vigorously, let layers sep. (line of division should be sharp), drain, and discard lower layer. Repeat extn with four 30 mL portions NaCl soln and once with 6 mL  $\text{H}_2\text{O}$ , draining and discarding exts each time. Drain remaining isoamyl alcohol-oil layer into 500 mL erlenmeyer. Wash separator once with 25 mL Et alcohol and combine with soln in flask. Add phthln, make liq. just pink with ca 0.2*N* stdzd KOH, and then add from pipet exactly 20 mL std KOH in excess.

Reflux soln 45 min on hot plate; then cool with flask loosely stoppered. Add ca 150 mL  $\text{H}_2\text{O}$  and rotate ca 30 sec, but avoid violent shaking. Transfer liq. into 500 mL separator thru short-stem funnel, rinse flask with 20 mL  $\text{H}_2\text{O}$ , and add to separator. Stopper funnel and let layers sep. Drain lower layer into original flask. Add ca 60 mL  $\text{H}_2\text{O}$  to separator, invert, and rotate to mix; then let layers sep. until most of aq. layer seps. (Small layer of emulsion may remain between layers.)

Drain aq. layer into flask, retaining any emulsion in separator. Keep flask and separator stoppered between addns to avoid contact with air. Add ca 100 mL  $\text{H}_2\text{O}$  to separator, shake vigorously, and drain entire contents into 250 mL centrf. bottle. Stopper, and centrf. until 2 well sepd layers are obtained. Blow off lower layer in centrf. bottle, using expeller, into flask contg aq. fractions previously sepd, add ca 0.2 mL phthln, and titr., using stdzd 0.2*N* HCl. As end point approaches, repeat addn of indicator and titr. to disappearance of pink. (Liq. becomes white or grayish.)

Conduct blank detn similarly, using same amts of all reagents. Subtract titrn of sample from that of blank to obtain equiv. of 0.2*N* alkali consumed. 1 mL 0.2*N* alkali = 39.2 mg esters as linalyl acetate.

**Pinene (33)—Official Final Action****19.095 Qualitative Test**

(Caution: Ethyl nitrite may be harmful. Avoid contact with skin and breathing vapor.)

Mix 10% distillate, 19.082, with 5 mL HOAc, cool mixt. thoroly in freezing bath, and add 10 mL *Et nitrite*. Add 2 mL HCl (2+1) slowly with const stirring. Keep mixt. in freezing bath 15 min. Collect crystals formed on filter, using suction, and wash with alcohol. Return combined filtrate and washings to freezing bath 15 min. Collect addnl crystals formed on original filter. Wash combined crops of crystals thoroly with alcohol. Dry at room temp. and dissolve in min. vol. of  $\text{CHCl}_3$ . Add MeOH to  $\text{CHCl}_3$  soln, little at time, until nitrosochlorides crystallize out. Mount sepd and dried crystals in olive oil and examine under microscope. Pinene nitrosochloride crystals have irregular pyramidal ends; limonene nitrosochloride crystallizes in needles.

**ALMOND EXTRACT****Alcohol—Official First Action****19.096 Method I (34)**

Fill 50 mL pycnometer with sample at 15.56°, and empty into separator contg ca 10 g NaCl. Wash out pycnometer several times with satd NaCl, using total of ca 100 mL. Ext twice with 50 mL portions pet ether (bp 40–60°). Collect pet ether ext in second separator and wash with two 25 mL portions satd NaCl soln. Combine original NaCl soln with washings, add little *powd pumice*, and distil into 100 mL pycnometer (Fig. 9:01). When almost 100 mL collects, dil. to vol. with H<sub>2</sub>O at convenient temp. and det. alcohol from sp gr as in 9.013, using table, 52.003.

**19.097 Method II (35)**

Det. sp gr of ext at 15.56/15.56° or at 20/20° as in 9.011 and benzaldehyde content as in 19.099. Apply formula given in 19.054, using benzaldehyde content as % oil found.

**19.098 Method III (Gas Chromatographic Method)  
Official First Action**

See 19.001–19.002.

**Benzaldehyde****19.099 Gravimetric Method (36)—Official First Action**

Measure 10 mL sample into each of two 300 mL erlenmeyers and add 10 mL *phenylhydrazine soln* (3 mL HOAc, 40 mL H<sub>2</sub>O, 2 mL phenylhydrazine) to one flask and 15 mL to other. Let mixts stand overnight in dark place.

Add 200 mL H<sub>2</sub>O and filter thru weighed gooch provided with thin layer of asbestos. Wash ppt first with cold H<sub>2</sub>O and finally with 10 mL 10% alcohol. Dry 3 hr at 70° at pressure ≤100 mm Hg (13.3 kPa) or to const wt over H<sub>2</sub>SO<sub>4</sub>. Wt ppt × 5.408 = wt benzaldehyde in 100 mL sample. If the 2 detns do not agree, repeat operation, using larger vol. phenylhydrazine soln.

**Alternative Gravimetric Method (37)  
Official Final Action****19.100****Reagent**

*2,4-Dinitrophenylhydrazine soln.*—Add 50 mL alcohol to 3.0 g 2,4-dinitrophenylhydrazine. Slowly add 10.0 mL H<sub>2</sub>SO<sub>4</sub> while stirring. After reagent dissolves, add addnl 40 mL alcohol and filter thru Whatman No. 12 paper.

**19.101****Determination**

Measure sample contg ca 10–50 mg benzaldehyde (ca 5 mL flavors, 100–200 mL cordials) into distn flask. Add enough alcohol to ensure ≥10% by vol. in distillate and dil. to ca 150 mL for flavors and 250 mL for cordials with H<sub>2</sub>O. Distil ca 100 mL flavors and 200 mL cordials and collect in vol. flask in ice bath. Transfer distillate to 600 mL beaker (also in ice bath) with 100 mL chilled alcohol. Add 25 mL H<sub>2</sub>SO<sub>4</sub>, mix thoroly, and immediately add 25 mL 2,4-dinitrophenylhydrazine soln, while stirring. Heat on steam bath or hot plate 30 min at ca 75°, stirring occasionally (avoid boiling).

Remove from heat, let ppt settle, and filter by decanting most of supernate thru weighed gooch prepd with thin asbestos mat before transferring bulk of ppt. Wash ppt with ca 25 mL H<sub>2</sub>O at room temp. or below. Dry at 100° to const wt (ca 2 hr).

Wt benzaldehyde = wt ppt × 0.3707.

**Ultraviolet Spectrophotometric Method (37)  
Official Final Action****19.102****Reagents and Apparatus**

(a) *Spectrophotometer.*—Quartz spectrophtr, Beckman Model DU, or equiv., with UV sensitive phototube and H lamp.

(b) *Benzaldehyde.*—Redistd; sp gr 1.041–1.046.

(c) *Alcohol.*—Reagent grade alcohol or MeOH.

(d) *Benzaldehyde std soln.*—Weigh 1 g benzaldehyde into 100 mL vol. flask and dil. with alcohol. Transfer 1 mL of this soln to 100 mL vol. flask, using 10% alcohol. Dil. 1, 2, 4, 6, 8, 10 mL aliquots to 100 mL with 10% alcohol (1, 2, 4, 6, 8, 10 ppm benzaldehyde).

**19.103****Determination**

Pipet sample (usually ca 5 mL flavor or 25 mL cordial) into distn flask. Add enough alcohol to ensure min. of 10% alcohol in distillate. Add ca 110 mL H<sub>2</sub>O to flavor or 200 mL H<sub>2</sub>O to cordial and distil, collecting 100 mL or 200 mL, resp. If necessary, dil. aliquot of distillate with 10% alcohol to produce *A* of ca 0.5 at 249 nm, using 10% alcohol blank.

Det. *A* of std benzaldehyde solns at 249 nm against blank of 10% alcohol, and plot std curve.

Det. benzaldehyde concn from *A* of sample at 249 nm and std curve, or calc. av. *A* of 1 ppm benzaldehyde (*A'*).

Concn of benzaldehyde in ppm = (*A/A'*) × *F*,

where *F* is diln factor. (For most accurate work conduct 5 ppm std with each detn.)

For flavors giving higher *A* than std at 222 nm, subtract av. of *A* for minima at 222 and 350 nm from *A* for max. at 249 nm to calc. *A*.

**19.104 Benzoic Acid (38)—Official First Action**

Measure 10 mL sample into 100 mL flask and add 10 mL 10% NaOH soln and 20 mL 3% H<sub>2</sub>O<sub>2</sub> soln; cover with watch glass and place in 100° oven. Oxidn of aldehyde to benzoic acid begins almost immediately; continue heating 5–10 min after all benzaldehyde odor disappears (20–30 min).

Remove flask from oven, transfer contents to separator, rinsing off watch glass, add 10 mL H<sub>2</sub>SO<sub>4</sub> (1+5), and cool contents of funnel to room temp. under tap. Ext benzoic acid with 25, 25, 20, and 20 mL portions ether, and wash combined exts with 2 portions of 5–10 mL H<sub>2</sub>O, or until all H<sub>2</sub>SO<sub>4</sub> is removed. Filter into weighed dish, evap. at room temp., dry overnight in desiccator, and weigh the benzoic acid. Multiply result by 10.

Multiply g/100 mL benzaldehyde obtained in 19.099, 19.101, or 19.103 by 1.151 to obtain equiv. of benzoic acid and subtract this product from g/100 mL total benzoic acid obtained above. Difference = g benzoic acid/100 mL ext.

**Hydrocyanic Acid****19.105 Qualitative Test—Procedure**

To several mL sample add several drops freshly prepd 3% FeSO<sub>4</sub>·7H<sub>2</sub>O soln and single drop 1% FeCl<sub>3</sub>·6H<sub>2</sub>O soln. Mix thoroly and add 10% NaOH soln, dropwise, until no further ppt forms and then H<sub>2</sub>SO<sub>4</sub> (1+9) to dissolve ppt. In presence of even small amts of HCN, Prussian blue coloration or suspension develops.

**19.106 Quantitative Method—Official Final Action**

(In absence of chlorides)

Measure 25 mL sample into small flask and add 5 mL *freshly*

*pptd*  $Mg(OH)_2$ , Cl-free. Titr. with 0.1*N*  $AgNO_3$ , using  $K_2CrO_4$  as indicator. 1 mL 0.1*N*  $AgNO_3$  = 0.0027 g HCN.

#### Nitrobenzene

#### 19.107 ★ Qualitative Test—Procedure ★

See 19.094, 10th ed.

### CASSIA, CINNAMON, AND CLOVE EXTRACTS

#### Alcohol—Official Final Action

#### 19.108 Method I

See 19.096.

#### 19.109 Method II (35)

Det. sp gr of ext at 15.56/15.56° or 20/20° as in 9.011, and oil as in 19.112, and apply formula given in 19.054. Use following values for sp gr of the oil: cassia, 1.05; cinnamon, 1.03; and clove, 1.055.

#### 19.110 Method III (Gas Chromatographic Method) Official First Action

See 19.001–19.002.

#### 19.111 Isopropanol—Official Final Action

See 19.057–19.059.

#### 19.112 Oil (39)—Official First Action

Pipet 10 mL sample into Babcock milk test bottle. Remove nearly all alcohol by blowing air into bottle thru small glass tube 30 min, or longer if necessary. From 10 mL buret add 1 mL *sol.v.* (equal parts USP mineral oil and  $H_2O$ -free kerosene), shake well, and fill with satd  $MgSO_4$  soln. Centrf. 10 min and read vol. of oil from extreme bottom to extreme top of column. To obtain % oil subtract 5 divisions and multiply remainder by 2.

### GINGER EXTRACT

#### 19.113 Alcohol—Official First Action

See 9.013.

#### 19.114 Solids (40)—Official First Action

Evap. 10 mL sample nearly to dryness on steam bath, dry 2 hr at 100°, and weigh.

#### 19.115 Ginger (Qualitative Test) (41) Official First Action

Dil. 10 mL sample to 30 mL, evap. to 20 mL, decant into separator, and ext with equal vol. ether. Let ether evap. spontaneously in porcelain dish, and to residue add 5 mL 75%  $H_2SO_4$  (by wt) and ca 5 mg *vanillin*. Let stand 15 min and add equal vol.  $H_2O$ . In presence of ginger ext, soln turns azure blue.

#### 19.116 ★ Capsicum (Qualitative Test) ★ (42)—Official First Action

See 19.102, 10th ed.

### PEPPERMINT, SPEARMINT, AND WINTERGREEN EXTRACTS

#### Alcohol—Official First Action

#### 19.117 Method I

See 19.096.

#### 19.118 Method II (33)

Det. sp gr at 15.56/15.56° or at 20/20° as in 9.011, and oil content as in 19.112, and apply formula in 19.054. Use following values for sp gr of oil: peppermint, 0.90; spearmint, 0.93; and wintergreen, 1.18.

#### 19.119 Method III (Gas Chromatographic Method) Official First Action

See 19.001–19.002.

#### 19.120 Isopropanol—Official Final Action

See 19.057–19.059.

#### 19.121 Oil—Official First Action

See 19.126.

### ANISE AND NUTMEG EXTRACTS

#### 19.122 Alcohol—Official First Action

See 19.001–19.002.

#### Oil (43)—Official First Action

#### 19.123 Method I

To 10 mL sample in Babcock milk test bottle add 1 mL HCl (1+1), then enough half-satd NaCl soln, previously heated to 60°, to fill flask nearly to neck. Stopper and let stand in  $H_2O$  at 60° ca 15 min, rotate occasionally, and centrf. 10 min at ca 800 rpm. Fill bottle to neck with satd NaCl soln and again centrf. 10 min. If sepn is not satisfactory or liq. is not clear, cool to ca 10° and centrf. addnl 10 min. Reading  $\times 2$  = % oil by vol.

#### 19.124 Method II

See 19.126.

### OTHER EXTRACTS AND TOILET PREPARATIONS

#### 19.125 Alcohol—Official First Action

See 19.001–19.002.

#### 19.126 Essential Oil (44)—Official First Action

(Applicable to exts of allspice, anise, caraway, lemon, nutmeg, orange, peppermint, pimiento, rosemary, thyme, wintergreen, and Me salicylate)

Pipet 10 mL sample (5 mL when oil content is >5% by vol.) into Babcock milk test bottle, add 0.50 mL *sol.v.* (equal parts USP mineral oil and  $H_2O$ -free kerosene) and 1 mL HCl (1+1), and fill to shoulder with satd NaCl soln. Shake bottle 3 min; then add the NaCl soln to bring column of oil within graduations on neck. Centrf. 10 min at high speed and read vol. oil from extreme bottom to extreme top of column. (Read from extreme bottom to bottom of meniscus at top of column for allspice, peppermint, and pimiento exts.) To obtain % oil, subtract 2.5 divisions and multiply remainder by 2. (Multiply by 4 if 5 mL sample is used.)

★ Surplus method—see inside front cover.

### Essential Oil in Emulsion (45) Official First Action

## 19.127

**Apparatus**

Use modified oil separator trap, Fig. 19:02, connected to 500 mL r-b flask thru  $\frac{3}{4}$  24/40 joint, and equipped with tight fitting condenser having projection at bottom to facilitate return of oil to trap.

## 19.128

**Determination**

Weigh 5–10 mL sample contg  $\leq 2$  mL essential oil in tared g-s graduate. Transfer to the 500 mL flask contg ca 200 mL  $H_2O$ , rinsing graduate by shaking with several 5 mL portions  $H_2O$ . Add rinsings to flask.

Fill oil trap with  $H_2O$  to overflowing, connect to flask and condenser, and carefully boil 1 hr. Remove heat and let stand several min. Remove enough  $H_2O$  from trap to bring oil layer within graduations, let stand 5 min to complete drainage, and measure amt of oil from bottom of lower meniscus to highest point of upper meniscus.

**Citral—Official Final Action****Barbituric Acid Condensation Method (46)**

## 19.129

**Reagent**

**Barbituric acid soln.**—Transfer 1.0 g reagent grade barbituric acid to dry 100 mL vol. flask. Add 20 mL  $H_2O$  from pipet, rinsing down neck of flask. Stopper lightly and dissolve by warming gently on hot plate or immersing in beaker of hot  $H_2O$ . Dil. gradually to vol., with shaking, with alcohol (or, preferably, anhyd. alcohol). Temper soln in  $H_2O$  bath at 25° (soln will contract slightly). Dil. back to vol. and mix thoroly. If some barbituric acid ppts on prolonged standing, redissolve by warming soln gently; then adjust to 25°.

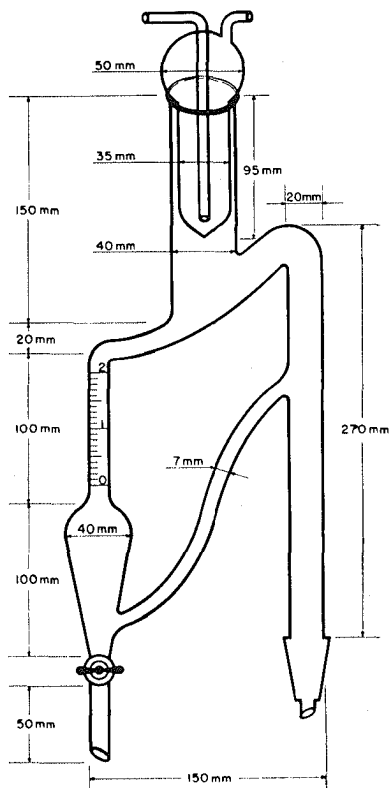

FIG. 19:02—Oil separator trap

Table 19:03 Weights and Volumes Used in Reaction

Oil	Sample Wt, mg	Reaction Vol., mL
Bergamot	70–80	10
Citronella	50–90	10
Grapefruit	100–150	10
Lemon	50–150	25
Lemongrass <sup>a</sup>	20–30	25
Lime		
expressed	30–60	25
distilled	100–600	5
Mandarin	100–250	10
Neroli	75–100	5
Orange		
sweet	150–400	10
bitter	150–400	10
Petitgrain	150–250	5
Tangerine	200–350	10

<sup>a</sup> Dil. 1 mL to 200 mL for A measurements.

## 19.130

**Determination**

Weigh suitable amt of oil into vol. flask of appropriate size, dil. to vol. with reagent, and place in  $H_2O$  bath at 25°. After 40 min, withdraw aliquots into vol. flasks half-filled with alcohol, shake gently to quench reaction, dil. to vol. with alcohol, and det. A of soln at 336 nm. Use similarly dild aliquot of reagent as cell blank. From A of sample, subtract corresponding A of untreated oil when similarly dild.

Use Table 19:03 as guide for sample wts and dilns. Except as noted, weigh indicated amts of oil into vol. flask for reaction; then dil. 2 mL to 50 mL with alcohol for A measurements.

## 19.131

**Calculations**

Convert A values to *a* at 336 nm of 1 g/L soln in 1 cm cell, and substitute in equation:

$$\% \text{ Citral} = 0.6153 \times [a \text{ of sample after reaction} - a \text{ of unreacted, similarly dild sample}]$$

**Beta-Ionone (47)—Official Final Action**19.132 **Method I**

(Applicable to pure solns contg  $\leq 100$  mg in 5 mL alcohol)

Place 5 mL alc. sample contg 10–100 mg  $\beta$ -ionone in 125 erlenmeyer. Add 95–100 mg solid *m*-nitrobenzhydrazide and dissolve by warming on steam bath, taking precautions to prevent loss of alcohol thru evapn. Add 5 mL  $H_2O$ , and if soln becomes cloudy, warm until clear. Remove from steam bath, add 0.2 mL HOAc, stopper flask lightly, and place on wooden surface to prevent too rapid cooling.

If  $\geq 20$  mg of  $\beta$ -ionone is present, crystals begin to form within 30 min after soln reaches room temp. Let stand in room  $\geq 2$  hr (overnight does no harm) and add 5 mL  $H_2O$  dropwise, mixing soln continuously during addn by rotating flask. Stopper, let stand in room  $\geq 1$  hr, and refrigerate overnight ( $\leq 48$  hr). Filter thru fine fritted glass crucible, wash with 30 mL dil. alcohol (3+7), using wet policeman to remove ppt adhering to flask, and dry at 100°. Wt ppt  $\times 0.541$  = wt  $\beta$ -ionone. Identify crystals microscopically, 19.135.

**Method II (48)**

(Applicable to raspberry concs)

## 19.133

**Apparatus**

(a) **Steam generator filled with water.**—Oil can holding 1 gal. (3.8 L) is convenient.

(b) *Distillation flask*.—R-b boiling flask with  $\frac{3}{8}$  24/40 joint, capacity ca twice vol. of sample to be used.

(c) *Still head*.—Adapter, 75° angle, with male connections  $\frac{3}{8}$  24/40 at bottom and side, and female connection 14/35 at top, with side arm lengthened and bent to fit vertical condenser.

(d) *Spray tube*.—Adapter, for use with Woulff bottles with  $\frac{3}{8}$  joints; aeration tube with  $\frac{3}{8}$  14/35, holes in bulb ca 2 mm diam., length of tubing such that when app. is set up, bulb is  $\leq 20$  mm above bottom of distg flask.

(e) *Condenser*.—Coil type with female connection  $\frac{3}{8}$  24/40 at top with 250–300 mm jacket and outlet tube lengthened to ca 200 mm to reach bottom of 500 mL erlenmeyer receiving flask.

#### 19.134

#### Determination

(Caution: See 51.011, 51.039, and 51.054.)

Place 250–1000 mL sample contg  $\leq 100$  mg  $\beta$ -ionone in distg flask and connect with app. Add enough  $H_2O$  to receiving flask to just cover outlet of condenser. Heat sample nearly to bp on asbestos mat with flame or by immersing it in boiling  $H_2O$  bath. As soon as sample reaches temp. of bath or just begins to boil, connect with steam generator and pass rapid current of steam thru sample until ca 500 mL distillate collects.

Add enough  $H_2O$  to distillate to reduce alcohol content to  $\leq 10\%$  and transfer to large separator. Add 150–200 mL ether, depending upon vol. of soln, so that ca 100 mL is obtained upon sepn. Shake thoroly ca 2 min. Let mixt. settle till clear and drain aq. layer till ca 25 mL remains in separator. Centrf. liq. and again let settle.

When clear, drain remainder of aq. layer; then drain ether soln into 125 mL erlenmeyer contg 95–100 mg *m*-nitrobenzhydrazide. After separator drains ca 1 min, close stopcock, pour 10–15 mL ether into separator to wash down sides, let soln settle 1 min, and add to main ether soln. Add 0.2 mL HOAc and dissolve solid reagent by stirring and breaking up lumps with glass rod, warming if necessary to complete soln. Let mixt. stand ca 1 hr and evap. on steam bath to ca 10 mL, passing current of air into flask to hasten evapn and keep down temp.

Meanwhile make second extn of distillate, using 100 mL ether. Add sepd ether soln to flask contg residue from first ether ext, follow with ether washings of separator, let stand  $\geq 15$  min, and evap. to 10 mL as before. Similarly make third extn, using 100 mL ether, add to flask, and evap. as before until 1–3 mL watery liq. and perhaps some oily residue remain.

While flask is still warm, add 5 mL alcohol from pipet, washing down sides of flask, and dissolve residue completely by warming on steam bath, protecting liq. against loss by evapn. Add 5 mL  $H_2O$  and warm if necessary to obtain clear soln. Add 0.2 mL HOAc, close with cork stopper, and place flask on wooden surface to prevent too rapid cooling.

After 2 hr, add 5 mL  $H_2O$  dropwise, mixing liq. by continuously rotating flask, stopper, and keep at room temp.  $\geq 1$  hr (overnight does no harm); then refrigerate overnight ( $\leq 48$  hr).

Filter on fine fritted glass crucible and wash with ca 30 mL dil. alcohol (3+7). Dry in vac. oven at 70° and weigh. Wt ppt  $\times 0.541$  = wt  $\beta$ -ionone. Identify crystals microscopically, 19.135.

If pptd material consists of oily matter mixed with cryst. matter, place fritted glass crucible in gouch holder attached to suction flask. Support test tube with wire within suction flask so as to catch any liq. that passes thru crucible. Add ca 5 mL pet ether, cover crucible, and let stand ca 5 min. Apply suction just long enough to carry thru any solv. that remains in crucible. Transfer pet ether soln to small beaker and let evap. spontaneously. Repeat several times until no more sol. matter is obtained by extn. Examine remaining contents of crucible and

several residues microscopically for crystals of  $\beta$ -ionone-*m*-nitrobenzhydrazide.

#### 19.135 Optical-Crystallographic Properties of Beta-Ionone-*m*-Nitrobenzhydrazide (49)—Procedure

This substance in mass is yellowish, but when examined in ordinary light under microscope it is essentially colorless and crystallizes in thin, rod-like plates, many having lath-like or frayed ends, some having 6-side outline. In parallel polarized light (crossed nicols), extinction is parallel and sign of elongation neg. Refractive indices are the min. value,  $n_\alpha = 1.548$ , invariably shown on elongated fragments when their long dimension is parallel to vibration plane of lower nicol (lengthwise), and max. value,  $n_\gamma = 1.648$ , usually shown on elongated fragments when their long dimension is at right angles to vibration plane of lower nicol (crosswise).

#### Ammonium Glycyrrhizinate (50)—Official Final Action

(Applicable to liqs)

#### 19.136

#### Principle

$NH_4$  glycyrrhizinate is hydrolyzed to glycyrrhetic acid, active ingredient in licorice, and this compd is silylated for GLC detn, with cholesterol as internal std. Method is applicable to 30–400 ppm  $NH_4$  glycyrrhizinate.

#### 19.137

#### Apparatus

*Gas chromatograph*.—With dual columns, H flame detector, and 1.2 m  $\times$  4 mm id glass or stainless steel columns packed with 1.5% OV-1 on 60–80 mesh Gas-Chrom Q (Applied Science Laboratories, Inc.). Operating conditions: temps (°)—detector 300, column 200–260, injection port 280; flow rates (mL/min)—N carrier gas and H 75, O 300; sensitivity 1000; or equiv. conditions so that 3–5  $\mu$ L silylated glycyrrhetic acid (6–9  $\mu$ g) and 3  $\mu$ L cholesterol internal std (1.5  $\mu$ g) will give  $\frac{1}{2}$  scale deflection. Retention times are ca 7 and 4 min, resp.

#### 19.138

#### Reagents

(a) *Silylating mixture*.—Mix, in order, following reagents: 5 vols anhyd. pyridine, 2 vols trimethylchlorosilane, and 3 vols *N,O*-bis(trimethylsilyl) acetamide (all available from Pierce Chemical Co.). (Caution: This mixt. is toxic; avoid contact with skin or eyes. Use effective fume removal device when prep, using, or heating mixt.) Store mixt. under N in tightly stoppered bottle and refrigerate when not in use. Refrigerated mixt. is stable indefinitely. Reagent is satisfactory if color of grains of activated indicating type silica gel desiccant (Grace Davison Chemical Co., Charles & Baltimore Sts, Baltimore, MD 21203) added to mixt. remains deep blue. Store anhyd. pyridine over Molecular Sieve 13 $\times$ .

(b) *Ammonium glycyrrhizinate std soln*.—1.0 mg/mL  $H_2O$ . Dissolve 100 mg purified  $NH_4$  glycyrrhizinate (MacAndrews & Forbes Co., 3rd St & Jefferson Ave., Camden, NJ 08104) in  $H_2O$  in 100 mL vol. flask and dil. to vol. with  $H_2O$ .

(c) *Cholesterol internal std soln*.—0.5 mg/mL. Weigh 5 mg USP cholesterol into 100 mL vol. flask and dissolve and dil. to vol. with MeOH.

#### 19.139

#### Determination

(Caution: See 51.011, 51.039, and 51.056.)

Pipet 25 mL sample, decarbonated if necessary, into 300 mL  $\frac{3}{8}$  24/40 r-b boiling flask, add 25 mL dioxane, and swirl to mix. Slowly add 25 mL  $H_2SO_4$  (1+3) and 2–3 SiC chips. Connect flask to  $H_2O$ -cooled condenser and reflux vigorously 1 hr. Add, thru

top of condenser, 75 mL H<sub>2</sub>O followed immediately by 100 mL CHCl<sub>3</sub> and reflux 15–20 min more. Let mixt. cool to room temp. and transfer to 500 mL separator. Add 100 mL ice-H<sub>2</sub>O and shake vigorously ca 1 min. Let phases sep. completely. Drain CHCl<sub>3</sub> layer into 250 mL separator contg 100 mL 2% NaHCO<sub>3</sub> soln. Shake and let layers sep. Filter CHCl<sub>3</sub> layer into 200 mL vol. flask thru 100 × 20 mm chromatgc tube or suitable glass funnel with glass wool plug and ca 25 g anhyd. Na<sub>2</sub>SO<sub>4</sub>. Repeat extns with 50 and 25 mL CHCl<sub>3</sub>, swirling to prevent emulsions. Filter as before and dil. to vol. with CHCl<sub>3</sub> passed thru same Na<sub>2</sub>SO<sub>4</sub>.

Transfer all of 200 mL ext (or aliquot if concn of active ingredient is ≥400 ppm) to 250 mL beaker, add 2–3 SiC chips, and evap. to 10–15 mL on steam bath under gentle N flow. Transfer quant. to 30 mL screw-cap bottle with Teflon liner. Add 2 mL cholesterol internal std soln, (c). Evap. to dryness on steam bath with gentle N flow. Flush bottle until cool with N or cool in desiccator. Add 1 mL silylating mixt., (a), and stopper bottle tightly. Rotate bottle so that reagent comes in contact with all glass surfaces. Let stand ca 4 hr at 50° or overnight at room temp. Inject 2–5 µL into gas chromatograph operated as in 19.137. Attenuate or inject larger amts for desired peak hts.

## 19.140

## Calculations

Det. relative response actor (*RF*) from chromatogram of 6 mL NH<sub>4</sub> glycyrrhizinate std soln, (b), and 19 mL H<sub>2</sub>O pipetted into 300 mL 24/40 r-b boiling flask, hydrolyzed, and silylated as in 19.139. Use peak areas obtained by triangulation.

$RF = [(PA_{AG} \times S_{AG}) / (PA_C \times S_C)] \times (W_C / W_{AG})$ , where subscripts AG and C refer to hydrolyzed std NH<sub>4</sub> glycyrrhizinate (glycyrrhetic acid) and cholesterol internal std, resp.; *PA* = peak area; *S* = attenuation; and *W* = mg std weighed.

$$\text{ppm AG } (\mu\text{g/mL}) = [(PA_{\text{sample}} \times S_{\text{sample}}) / (PA_C \times S_C)] \times (W_C \times 10^3 / RF) \times (1/V),$$

where *V* = mL sample.

## 20. Food Additives: Direct

### ACIDULANTS

#### Fumaric Acid (7)—Official Final Action

20.001

#### Apparatus

**Polarograph.**—Any voltammetric or polarographic instrument with necessary accessories (cells, electrodes, Hg, capillaries, etc.) capable of effectively scanning up to 3.0 volts in either pos. or neg. direction starting at selected initial potential.

20.002

#### Reagents

(a) **Fumaric acid std solns.**—(1) *Stock soln.*—500  $\mu\text{g/mL}$ . Transfer 50 mg fumaric acid to 100 mL vol. flask. Dissolve in and dil. to vol. with MeOH. (2) *Working std soln.*—25  $\mu\text{g/mL}$ . Pipet 5 mL stock soln into 100 mL vol. flask, add 15 mL MeOH, and dil. to vol. with electrolyte soln.

(b) **Electrolyte soln.**—Dissolve 7.70 g  $(\text{CH}_3)_4\text{NBr}$  and 0.210 g LiCl in  $\text{H}_2\text{O}$  and dil. to 500 mL. (LiCl is very hygroscopic; weigh rapidly with min. exposure to air.)

(c) **Nitrogen gas.**—Purified  $\text{H}_2\text{O}$ -pumped N in cylinder.

20.003

#### Preparation of Sample Solutions

(a) **Sample soln A.**—(1) *Aqueous samples (fruit juice drinks, etc.).*—If insol. matter is present, shake with Celite and filter. Transfer 25.00 g clear soln to 100 mL vol. flask, using MeOH, and dil. to vol. with MeOH. (2) *Powders.*—Shake weighed sample with measured vol. MeOH. Filter, or use clear supernate.

(b) **Sample test soln B.**—Use in preliminary detn. Transfer  $\leq 5$  mL *sample soln A* to 25 mL vol. flask (if  $< 5$  mL is taken, add MeOH to make 5 mL) and dil. to vol. with electrolyte soln.

(c) **Sample test soln C.**—Use in final detn. After preliminary detn is performed on *sample test soln B*, adjust wt of sample to give final concn of *sample test soln C* of 25  $\mu\text{g}$  fumaric acid/mL, prepg soln as in (b).

20.004

#### Preparation of Standard Curve

Transfer 1, 3, and 5 mL fumaric acid stock soln to sep. 25 mL vol. flasks. To flasks contg 1 and 3 mL stock soln, add 4 and 2 mL MeOH, resp. Dil. all flasks to vol. with electrolyte soln. Polarograph solns as in detn. Plot numerical values of solns against  $\mu\text{g}$  fumaric acid/mL.

20.005

#### Determination

Prep. polarograph cell and pass N thru *sample test soln B* 3 min at ca 3–5 bubbles/sec. Polarograph, using starting potential of  $-0.8$  v. Peak potential of fumaric acid under these conditions is ca  $-1.15$  v with Hg pool electrode. Wave ht  $\times$  instrument scale factor gives “numerical value,” which shows relative concn of fumaric acid in polarographed soln. From numerical value of *sample test soln B* and std curve, calc. approx. % fumaric acid in sample.

Make second detn, using calcd wt sample for *sample test soln C* contg 25  $\mu\text{g}$  fumaric acid/mL and working std soln contg exactly 25  $\mu\text{g}$  fumaric acid/mL. Polarographic values of sample and std should be very close. From second detn calc.:

(a)  $\text{mg fumaric acid/mL in sample test soln C} = (\text{mg fumaric acid/mL in working std soln} (= 0.025)) \times (\text{numerical value of sample test soln C}) / (\text{numerical value of working std soln})$ .

(b)  $\% \text{ fumaric acid in sample} = (\text{mg fumaric acid/mL in sample test soln C}) \times (\text{mL sample test soln C} (= 25)) \times 100 / (\text{mg}$

sample in aliquot *sample soln A* used in prepg *sample test soln C*).

### ANTIOXIDANTS

#### Qualitative Tests (2)—Official Final Action

(Caution: See 51.011, 51.039, and 51.073.)

20.006

#### Reagents

(a) **Barium hydroxide.**—1%  $\text{Ba}(\text{OH})_2 \cdot \text{H}_2\text{O}$  in boiled distd  $\text{H}_2\text{O}$ . Keep in tightly stoppered bottle.

(b) **Ehrlich reagent.**—Diazobenzene sulfonic acid. Prep. 0.5% soln  $\text{NaNO}_2$  in  $\text{H}_2\text{O}$  and 0.5% soln sulfanilic acid in HCl (1+19). Prep.  $\text{NaNO}_2$  soln fresh every 3 weeks. Keep solns refrigerated. Mix  $\text{NaNO}_2$  and sulfanilic acid solns (1+100) daily.

(c) **Dianisidine soln.**—(Caution: Dianisidine may be harmful. See 51.084.) Dissolve 250 mg dianisidine (3,3'-dimethoxybenzidine) in 50 mL anhyd. MeOH. Add 100 mg activated charcoal, shake 5 min, and filter. Mix 40 mL clear filtrate with 60 mL 1*N* HCl. Prep. daily and protect from light.

(d) **Activated Florisil adsorbent.**—60–100 mesh. Activated by manufacturer at 260° or 650° (available from Floridin Co.).

Test Florisil for BHT retention as follows: Add 0.2 mg BHT in 25 mL pet ether to prepd column, 20.007, elute with 150 mL pet ether, and apply BHT test after evapg ether just to dryness as in 20.008(d). If BHT is not eluted, activate remaining Florisil by heating 2 hr at 650°, cool, add 6.5%  $\text{H}_2\text{O}$  by wt, and homogenize by shaking 1 hr in closed container.

20.007

#### Preparation of Florisil Column for Cleanup of BHT Extract

Insert small glass wool plug into chromatgc tube 20 (od)  $\times$  250 mm with Teflon stopcock, and add ca 12 g Florisil with gentle tapping. Wash with two 15 mL portions pet ether, adding second portion when liq. level drops to just above top of Florisil. When level of second portion is ca 1 cm above Florisil, close stopcock. Do not let column become dry.

20.008

#### Tests

(a) **Propyl gallate (PG).**—Weigh ca 30 g fat (melted by gentle warming) or oil, dissolve in ca 60 mL pet ether, and transfer to 250 mL separator. Add 15 mL  $\text{H}_2\text{O}$  and shake gently 1 min. Let sep. and drain aq. phase into 125 mL separator, leaving any emulsion in org. phase. Repeat extn of pet ether with 2 addnl 15 mL portions  $\text{H}_2\text{O}$  and reserve pet ether soln for further extn with  $\text{CH}_3\text{CN}$ , (b). Add 15 mL ether to combined aq. exts and shake 1 min. Discard aq. phase and evap. ether just to dryness in small beaker. Add 4 mL 50% alcohol to residue, swirl, and add 1 mL  $\text{NH}_4\text{OH}$ . If soln turns rose, PG is present. (Color is unstable and fades after few min.)

(b) **Nordihydroguaiaretic acid (NDGA).**—Ext pet ether soln from (a) by shaking 2 min with 20 mL  $\text{CH}_3\text{CN}$ . Let layers sep. and drain  $\text{CH}_3\text{CN}$  into 1 L separator. Repeat extn with 2 addnl 30 mL portions  $\text{CH}_3\text{CN}$  and discard pet ether. Dil. combined  $\text{CH}_3\text{CN}$  exts with 400 mL  $\text{H}_2\text{O}$ , add 2–3 g NaCl, and shake 2 min with 20 mL pet ether. Let layers sep., and drain dild  $\text{CH}_3\text{CN}$  into second 1 L separator. Ext dil.  $\text{CH}_3\text{CN}$  with 2 addnl 20 mL portions pet ether and reserve dild  $\text{CH}_3\text{CN}$  soln for further extn. Combine pet ether exts in 100 mL beaker and set aside for BHA and BHT tests.

Add 50 mL ether-pet ether (1+1) to dild  $\text{CH}_3\text{CN}$  and shake 2 min. (*Caution:* Vent separator.) Let layers sep., discard  $\text{CH}_3\text{CN}$ , and evap. ether just to dryness in small beaker. Add 4 mL 50% alcohol, swirl, and then add 1 mL 1%  $\text{Ba}(\text{OH})_2$  soln and mix. If NDGA is present, soln turns blue and fades rapidly.

(c) *Butylated hydroxyanisole (BHA)*.—Take  $\frac{1}{3}$  of combined pet ether soln reserved for BHA-BHT tests and evap. just to dryness in small beaker, using gentle heat, under air current. Add 2.5 mL alcohol to dissolve residue and dil. with 2.5 mL  $\text{H}_2\text{O}$ . Swirl, add 1 mL Ehrlich reagent, immediately add 1 mL 1N  $\text{NaOH}$ , and swirl again. If soln turns red-purple, BHA is present.

(d) *Butylated hydroxytoluene (BHT)*.—Pass remaining  $\frac{2}{3}$  combined pet ether soln thru Florisil column and elute with 150 mL pet ether. Collect eluate in 200 mL beaker and evap. just to dryness. Add 2.5 mL alcohol, swirl, and dil. with 2.5 mL  $\text{H}_2\text{O}$ . Add 2 mL dianisidine soln and mix. Add 0.8 mL 0.3%  $\text{NaNO}_2$  soln. Mix, and let stand 5 min; then transfer to small separator. Add 0.5 mL  $\text{CHCl}_3$ , shake vigorously 30 sec, and let sep. If  $\text{CHCl}_3$  turns pink to red, BHT is present. Confirm BHT by comparing spectrophtric curve of colored  $\text{CHCl}_3$  ext with control prep'd from ref. std BHT as follows: Dissolve ca 15 mg BHT in 5 mL aq. alcohol (1+1), add 2 mL dianisidine soln, and proceed as above.

**Butylated Hydroxyanisole (BHA) and  
Butylated Hydroxytoluene (BHT)  
(3)—Official Final Action**

(*Caution:* See 51.011, 51.039, 51.040, 51.048, and 51.049.)

**20.009****Principle**

BHA and BHT are extd from ready-to-eat breakfast cereals with  $\text{CS}_2$  and detd by GLC, using flame ionization detection.

**20.010****Apparatus**

(a) *Gas chromatograph*.—With H flame ionization detector. *Operating conditions:* temps ( $^{\circ}$ )—column 160, detector 210, flash heater 200; N flow rate, to elute BHT in 3–4 min from QF-1 column and elute BHA in 3–4 min from Apiezon column; H flow rate, ca 40 mL/min for Apiezon and ca 25 mL/min for QF-1; air flow rate, ca 340 mL/min; electrometer sensitivity,  $500 \times (5 \times 10^{-10}$  amp full scale deflection) with 1 mv recorder. Adjust H and air flow rates if necessary. Alternatively, adjust electrometer sensitivity so 0.1  $\mu\text{g}$  BHA gives ca 50% deflection. Repeat injections until const peak hts are obtained on successive injections of identical vol. of std mixt.

Order of appearance from Apiezon column (1.2 m; 4'): BHA, BHT, di-BHA. Order of appearance from QF-1 column (1.8 m; 6'): BHT, BHA, di-BHA.

Use of 2 GLC columns serves to identify BHA and BHT. Use Apiezon L/Gas-Chrom Q, 1.2 m column to resolve 2- and 3-isomers of BHA. Adjust GLC parameters to obtain good sepn of BHA isomers, such as adjusting column temp. to  $150^{\circ}$  and electrometer sensitivity to  $1000 \times$ . Adjust amt BHA std injected to give 50% deflection.

(b) *GLC columns*.—Glass, 1.2 m (4')  $\times$  4 mm and 1.8 m (6')  $\times$  4 mm, packed with Apiezon L and QF-1 silicone oil (Fluoro silicone fluid, FS 1265), resp., on 80–100 mesh Gas-Chrom Q (Applied Science Laboratories). Prep. columns and column material by carefully washing insides of tubes and small amt fine glass wool with dichlorodimethylsilane soln, rinsing with MeOH, and drying. (*Caution:* Dichlorodimethylsilane is toxic. Avoid contact with skin and eyes. Use effective fume removal device.)

Slowly sprinkle ca 50 g Gas-Chrom Q into 800 mL beaker

almost filled with  $\text{CCl}_4$ . Remove fine particles that remain on surface with vac. line and trap. Decant solv. and dry GLC support.

Transfer 20.0 g dried Gas-Chrom Q to 500 mL r-b flask. Add 100 mL  $\text{CHCl}_3$  or  $\text{CH}_2\text{Cl}_2$  and mix gently. Dissolve 1.0 g Apiezon L or 2.0 g QF-1 in 50 mL  $\text{CHCl}_3$  or  $\text{CH}_2\text{Cl}_2$ , add to flask, and mix gently. Evap. to dryness, using rotary vac. evaporator and  $\text{H}_2\text{O}$  bath ( $35^{\circ}$  for  $\text{CH}_2\text{Cl}_2$  and  $70^{\circ}$  for  $\text{CHCl}_3$ ).

Carefully plug exit of column with small plug of fine glass wool and thru-hole septum. Apply vac. to exit port and slowly add coated support (Apiezon L/Gas-Chrom Q for 1.2 m column; QF-1/Gas-Chrom Q for 1.8 m column) thru injection port, tapping very gently to aid compaction. Pack to within 1 cm of area heated by flash heater. Plug with fine glass wool and condition ca 3 days at  $200^{\circ}$  with slow stream of N (ca 10 mL/min) or until steady baseline is obtained.

(c) *Chromatographic tube*.—25  $\times$  200 mm glass tube with small drip tip (6 mm od  $\times$  50 long), with or without medium porosity fritted disk, with close-fitting tamping rod.

(d) *Fine glass wool*.—Wash with  $\text{CS}_2$  and dry.

**20.011****Reagents**

(a) *Carbon disulfide*.—Reagent grade; nearly colorless. If distinctly yellow, distil before use.

(b) *BHA, BHT, and di-BHA std mixture*.—0.02  $\mu\text{g}/\mu\text{L}$  each of BHA, BHT, and di-BHA in  $\text{CS}_2$ . Dissolve 1.00 mg each of BHA and BHT in small amt  $\text{CS}_2$ , add 10.0 mL internal std soln, and dil. to 50 mL with  $\text{CS}_2$  or prep. by diln of more concd solns with  $\text{CS}_2$ . Prep. fresh and store in low-actinic glassware.

(c) *Internal std soln*.—0.1  $\mu\text{g}$  di-BHA/ $\mu\text{L}$   $\text{CS}_2$ . Prep. fresh and store in low-actinic glassware.

(d) *Dichlorodimethylsilane soln*.—Dil. 5 mL to 100 mL with toluene.

**20.012****Determination**

(Protect all solns from light; complete assay in 1 day. Use either GLC column for analysis.)

Grind sample to pass No. 20 sieve and mix well. (When necessary, ground sample may be stored frozen under N for few days.) Place, if necessary, small plug of fine glass wool at bottom of chromatgc tube, add 20.0 g sample to column, using tamping rod to pack it firmly without solv., and top column with another small glass wool plug, tamped down. Mark 100 mL beaker at 50 mL level and place under column to collect eluate. Add three 5 mL portions  $\text{CS}_2$  to column, letting each portion sink into column before adding next. Elute  $\text{CS}_2$  at ca 5 mL/min; use N, if necessary, to maintain flow rate.

Add several 10 mL portions  $\text{CS}_2$ , letting each portion sink into column until 50 mL eluate collects. Rinse tip of column with small amt  $\text{CS}_2$ . Accurately add di-BHA to eluate to obtain concn after evapn of 0.02  $\mu\text{g}$  di-BHA/ $\mu\text{L}$  final soln. Evap. eluate under gentle stream of N in hood at room temp. to small vol. ( $<5.0$  mL). Accurately dil. evapd sample to appropriate vol. (e.g., 5.0 mL) for GLC analysis. Inject 3.0–9.0  $\mu\text{L}$  sample, using 10  $\mu\text{L}$  syringe, into gas chromatograph. Before and after each series of sample chromatograms, inject 3.0–9.0  $\mu\text{L}$  std mixt. and average std values for calcs. Measure each peak ht in mm. (Ht of BHA, BHT, and di-BHA peaks should be in range of 30–95% full scale deflection.)

Calc. ppm antioxidant present, correcting for internal std, as follows:

$$\text{ppm BHA or BHT} = (H/H') \times (C'/C) \times (H'_i/H_i) \times (C_i/C'_i),$$

where  $H$  and  $H' = \text{ht (mm) of sample and std peaks, resp.; } H_i \text{ and } H'_i = \text{ht (mm) of internal std peaks in sample and std, resp.; } C \text{ and } C' = \text{concn of sample (g/}\mu\text{L) and std (}\mu\text{g/}\mu\text{L), resp.; and } C_i \text{ and } C'_i = \text{concn (}\mu\text{g/}\mu\text{L) of internal std in sample and std solns, resp.}$

#### Propyl Gallate (PG) (4)—Official First Action

(Caution: See 51.011, 51.039, and 51.073.)

##### 20.013

##### Reagents

(a) *Petroleum ether reagent*.—Mix 1 vol. 30–60° pet ether (14.088, or equiv.) with 3 vols 60–100° pet ether (Skellysolve B and H have been found satisfactory) and shake mixt. 5 min with  $1/10$  its vol.  $\text{H}_2\text{SO}_4$ . Discard acid layer, wash several times with  $\text{H}_2\text{O}$ , then once with 1% NaOH soln, and then again with  $\text{H}_2\text{O}$  until washings are substantially neut. Discard all washings and distil pet ether in all-glass app.

(b) *Ammonium acetate solns*.—1.25%, 1.67%, and 10% aq. solns. Soln contg 1.67%  $\text{NH}_4\text{OAc}$  in 5% alcohol may also be required.

(c) *Ferrous tartrate reagent*.—Dissolve 0.100 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  and 0.500 g Rochelle salt ( $\text{NaKC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ ) in  $\text{H}_2\text{O}$  and dil. to 100 mL. Reagent must be used within 3 hr of prepn.

(d) *Propyl gallate std soln*.—50  $\mu\text{g/mL}$ . Dissolve 50 mg PG in  $\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ .

##### 20.014

##### Preparation of Standard Curve

Place  $\geq 7$  aliquots of std soln, (d), covering range from 50 to 1000  $\mu\text{g}$ , in 50 mL g-s erlenmeyers. Add exactly 2.5 mL 10%  $\text{NH}_4\text{OAc}$  to each flask, dil. to exactly 24 mL with  $\text{H}_2\text{O}$ , and pipet 1 mL ferrous tartrate reagent into each flask. Let solns stand  $\geq 3$  min. Measure  $A$  at 540 nm against soln contg 20 mL 1.25%  $\text{NH}_4\text{OAc}$  soln, 4 mL  $\text{H}_2\text{O}$ , and 1 mL ferrous tartrate soln. Plot  $\mu\text{g}$  PG against  $A$ .

##### 20.015

##### Determination

Dissolve 40 g fat or oil in the pet ether reagent and dil. to 250 mL with this reagent. (Gentle warming may be necessary to obtain complete soln.) Pipet 100 mL fat soln into 250 mL separator. Ext fat soln with 20 mL aq. 1.67%  $\text{NH}_4\text{OAc}$  soln by continuously inverting separator 2.5 min. After phases sep. completely, drain aq. layer into 100 mL vol. flask, being careful not to let any oil droplets fall into flask. (Some shortenings show strong tendency to emulsify during aq. extn. To prevent emulsification, add 2 mL *n*-octanol to fat soln aliquot before beginning extn and use 1.67%  $\text{NH}_4\text{OAc}$  soln in 5% alcohol for extn in place of aq. soln. This procedure need be used only when usual method fails.) Repeat extn twice with 20 mL portions 1.67%  $\text{NH}_4\text{OAc}$  soln, combining aq. layers in vol. flask. Finally, ext fat soln with 15 mL  $\text{H}_2\text{O}$  30 sec and combine aq. layer with previous washings. Let layers sep. completely after each washing. Add exactly 2.5 mL 10%  $\text{NH}_4\text{OAc}$  soln to combined exts in vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . This soln now contains 1.25%  $\text{NH}_4\text{OAc}$ . Filter thru dry rapid paper to remove any turbidity. (Colors must be developed on same day ext is prepd. If combined exts stand more than several hr, yellow color may develop and solns must be discarded.)

Pipet aliquot of ext,  $\leq 20$  mL, into 50 mL g-s erlenmeyer. Dil. to 20 mL with 1.25%  $\text{NH}_4\text{OAc}$  soln. Add exactly 4 mL  $\text{H}_2\text{O}$  and pipet 1 mL ferrous tartrate reagent into flask. Mix well, and measure  $A$  at 540 nm against soln contg 20 mL 1.25%  $\text{NH}_4\text{OAc}$  soln, 4 mL  $\text{H}_2\text{O}$ , and 1 mL ferrous tartrate reagent. Calc. amt of PG from std curve.

## CHEMICAL PRESERVATIVES

### BENZOIC ACID

(Caution: See 51.011, 51.039, 51.040, 51.054, and 51.056.)

#### Qualitative Tests—Official Final Action

##### 20.016 Preliminary Test

Ext benzoic acid as in 20.094 or 20.096. If appreciable benzoic acid is present, it will crystallize from ether in shining leaflets having characteristic odor on warming. Dissolve cryst. deposit in hot  $\text{H}_2\text{O}$ , divide into 2 portions, and test as in 20.017 or 20.018. Deposit may also be purified as in 20.094(c) and mp detd.

##### 20.017 Ferric Chloride Test

Make soln, 20.016, alk. with few drops  $\text{NH}_4\text{OH}$ , expel excess  $\text{NH}_3$  by evapn, dissolve residue in few mL hot  $\text{H}_2\text{O}$ , filter if necessary, and add few drops aq. 0.5%  $\text{FeCl}_3$  soln. Salmon color ppt of ferric benzoate indicates presence of benzoic acid.

##### 20.018 Modified Mohler Test (5)

(Presence of phthln interferes)

To aq. soln, 20.016, add 1 or 2 drops ca 10% NaOH soln and evap. to dryness. To residue add 5–10 drops  $\text{H}_2\text{SO}_4$  and small crystal  $\text{KNO}_3$ . Heat 10 min in glycerol bath at 120–130° (must be  $\leq 130^\circ$ ). Cool, add 1 mL  $\text{H}_2\text{O}$ , and make distinctly ammoniacal. Boil soln to decompose any  $\text{NH}_4\text{NO}_2$  that may form. Cool, and add drop of fresh, colorless  $(\text{NH}_4)_2\text{S}$  soln, but do not let layers mix. Red-brown ring indicates benzoic acid. On mixing, color diffuses thruout liq., and on heating finally changes to greenish-yellow. This change differentiates benzoic acid from salicylic or cinnamic acids. Salicylic and cinnamic acids form colored compds that are not destroyed by heating.

#### Quantitative Methods—Official Final Action

(Presence of vanillin interferes (6))

##### Titrimetric Method

##### 20.019

##### Preparation of Sample

(a) *General method*.—Thoroughly mix sample, grinding if solid or semisolid. Transfer 150 mL or 150 g to 500 mL vol. flask, add enough pulverized NaCl to sat.  $\text{H}_2\text{O}$  in sample, make alk. to litmus paper with 10% NaOH soln or with milk of lime (1 part powd recently slaked  $\text{Ca(OH)}_2$  suspended in 3 parts  $\text{H}_2\text{O}$ ), and dil. to vol. with satd NaCl soln. Shake thoroughly, let stand  $\geq 2$  hr, shaking frequently, and filter. If sample contains large amts of fat, portions of which may contaminate filtrate, add few mL 10% NaOH soln to filtrate and ext with ether before proceeding as in 20.020. If alcohol is present, proceed as in (d). If sample contains large amts of matter precipitable by NaCl soln, proceed as in (e).

(b) *Catsup*.—Add 15 g pulverized NaCl to 150 g sample, and transfer mixt. to 500 mL vol. flask, rinsing with ca 150 mL satd NaCl soln. Make slightly alk. to litmus paper with 10% NaOH soln and dil. to vol. with satd NaCl soln. Let stand  $\geq 2$  hr, shaking frequently. Squeeze thru heavy muslin bag, and filter.

(c) *Jellies, jams, preserves, and marmalades*.—Digest 150 g sample in ca 300 mL satd NaCl soln. Add 15 g pulverized NaCl. Make alk. to litmus paper with milk of lime. Transfer to 500 mL vol. flask and dil. to vol. with satd NaCl soln. Let stand  $\geq 2$  hr, shaking frequently; centr. if necessary, and filter.

(d) *Cider containing alcohol, and similar products*.—Make 250 mL sample alk. to litmus paper with 10% NaOH soln and evap. on steam bath to ca 100 mL. Transfer to 250 mL vol. flask, add 30 g pulverized NaCl, and shake until dissolved. Dil. to original

vol. of 250 mL with satd NaCl soln; let stand  $\geq 2$  hr, shaking frequently, and filter.

(e) *Salted or dried fish*.—Wash 50 g ground sample into 500 mL vol. flask with  $H_2O$ . Make slightly alk. to litmus paper with 10% NaOH soln and dil. to vol. with  $H_2O$ . Let stand  $\geq 2$  hr, shaking frequently, and filter. Pipet as large a measured portion of filtrate as possible ( $\geq 300$  mL) into second 500 mL vol. flask, and add 30 g pulverized NaCl for each 100 mL soln. Shake until NaCl dissolves and dil. to vol. with satd NaCl soln. Mix thoroly, and filter off pptd protein and other extraneous matter.

## 20.020

### Determination

Pipet 100–200 mL filtrate, **20.019**, into separator. Neutze to litmus paper with HCl (1+3) and add 5 mL excess. With salted fish, protein usually ppts on acidifying, but ppt does not interfere with extn. Ext carefully with  $CHCl_3$ , using successive portions of 70, 50, 40, and 30 mL. To avoid formation of emulsion, shake cautiously each time, using rotary motion.  $CHCl_3$  layer usually seps readily after standing few min. If emulsion forms, break it by stirring  $CHCl_3$  layer with glass rod, by drawing off into second separator and giving 1 or 2 sharp shakes from one end of separator to other, or by centrfg few min. As this is progressive extn, carefully drain as much clear  $CHCl_3$  soln as possible after each extn, but do not drain any of emulsion with  $CHCl_3$  layer. If this precaution is taken,  $CHCl_3$  ext need not be washed.

Transfer combined  $CHCl_3$  exts to porcelain evapg dish, rinse container several times with few mL  $CHCl_3$ , and evap. to dryness at room temp. in current of dry air.

Ext may also be transferred from separator to 300 mL erlenmeyer and separator rinsed with three 5–10 mL portions  $CHCl_3$ . Distil very slowly at low temp. to ca  $\frac{1}{4}$  original vol. Transfer residue to porcelain evapg dish, rinsing flask with three 5–10 mL portions  $CHCl_3$ , and evap. to dryness at room temp. in current of dry air.

Dry residue overnight (or until no odor of HOAc can be detected if product is catsup) in desiccator contg  $H_2SO_4$ . Dissolve residue of benzoic acid in 30–50 mL alcohol neut. to phthln; add ca  $\frac{1}{4}$  this vol. of  $H_2O$  and 1 or 2 drops phthln; and titr. with 0.05N NaOH. 1 mL 0.05N NaOH = 0.0072 g anhyd. Na benzoate.

### Spectrophotometric Method (7)

(Applicable to catsup, other tomato products, jams, jellies, beverages contg small amts of alcohol, soft drinks, and fruit juices. Not applicable to solids.)

## 20.021

### Preparation of Standard Curve

Prep. soln of benzoic acid in ether contg 50 mg/L. Det. *A* of this soln in tightly stoppered cell in Beckman DU or recording spectrophtr between 265 and 280 nm in 1 nm intervals. Plot *A* against wavelength and record wavelength of min. at ca 267.5 nm as point *B*, other min. at ca 276.5 nm as point *D*, and highest max. at ca 272 nm as point *C*.

Prep. solns of benzoic acid in ether contg 20, 40, 60, 80, 100, and 120 mg/L. Det. *A* of these solns in tightly stoppered cell in spectrophtr at points *B*, *C*, and *D*. For each concn, average *A* at *B* and *D* and subtract this value from *A* at *C*. Plot difference against concn.

## 20.022

### Preparation of Sample

Mix sample thoroly. Transfer 10 g or 10 mL to separator and dil. to 200 mL with satd NaCl soln. Make soln definitely acid to litmus with HCl and mix well.

## 20.023

### Determination

Ext prepd soln with 70, 50, 40, and 30 mL portions ether, shaking well to ensure complete extn. (Break emulsions by standing, stirring, or centrfg.) Drain and discard aq. phase. Wash combined ether exts with 50, 40, and 30 mL portions HCl (1+1000) and discard HCl washings. (If ext requires no purification, proceed to next par.) Ext ether soln with 50, 40, 30, and 20 mL portions 0.1%  $NH_4OH$  and discard ether. Neutze combined  $NH_4OH$  exts with HCl and add 1 mL excess. Ext acidified soln with 70, 50, 40, and 30 mL ether.

Dil. combined ether exts to 200 mL with ether and det. *A* in tightly stoppered cell in spectrophtr at wavelengths *B*, *C*, and *D*, dilg with ether if necessary to obtain optimum concn of 20–120 mg/L. Average *A* at *B* and *D* and subtract this value from *A* at *C*. Det. concn benzoic acid from std curve, correcting for dilns. Benzoic acid  $\times 1.18$  = Na benzoate.

Conduct detn similarly on benzoate-free sample of product and det. *A* in region 265–280 nm at 1 nm intervals. If curve is straight line in this region, method is applicable to this product.

### Thin Layer Chromatographic Method (8) Official First Action

## 20.024

### Apparatus and Reagents

(a) *Steam distillation apparatus*.—See Fig. 20:01. (1) Connecting tube only, with flask joint  $\frac{1}{8}$  34/45 and condenser joint  $\frac{1}{8}$  24/40 (JD 1710); (2) Kjeldahl flask, 800 mL, with outer joint  $\frac{1}{8}$  34/45 (JF 6030); (3) condenser, 30 cm with outer joint  $\frac{1}{8}$  24/40 at top and drip tip at delivery end (JC 6400); (4) steam generator, see **18.050(a)**; (5) variable transformers, 10 amp; and (6) Glas-Col heating mantle, 500 mL (11-472-10F). (Items 1–3 cite SGA Scientific Inc. Nos; items 5 and 6 cite Fisher Scientific Co. Nos.)

(b) *Ultraviolet recording spectrophotometer and accessories*.—Recording between 250 and 350 nm; with 5 cm micro cells and cell adapter (Pyrocell Mfg. Inc., PO Box 176, Westwood, NJ 07675, Nos. 5009, 5009A).

(c) *Thin layer chromatographic equipment and adsorbents*.—See **29.006**; kieselguhr G and silica gel GF 254 (Brinkmann Instruments, Inc.).

## 20.025

### Preparation of Plates

In 250 mL erlenmeyer, mix 10 g each of kieselguhr G and silica gel GF 254. Add 45 mL  $H_2O$  and shake 30 sec. Set applicator

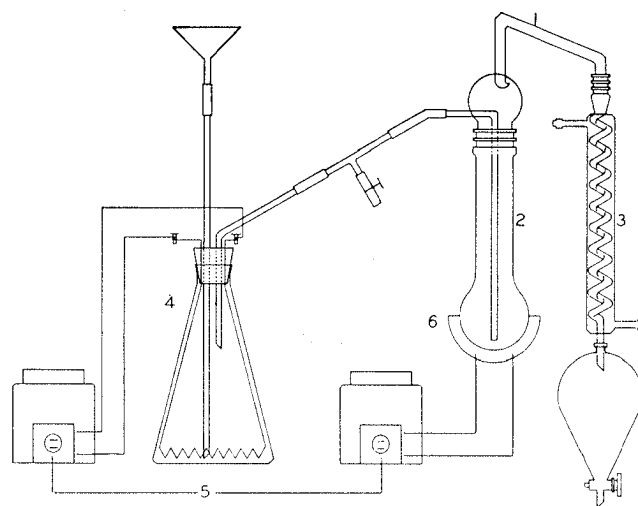

FIG. 20:01—Steam distillation apparatus

at 0.25 mm and apply mixt. to 5 glass plates. Air dry 10 min and dry in forced-draft oven 1 hr at 100°.

**20.026****Preparation of Sample**

(a) *Liquids*.—Accurately weigh ca 50–60 g sample directly into 800 mL Kjeldahl flask. Continue as in (c), beginning "Add 200 g  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  . . ."

(b) *Solids*.—Accurately weigh ca 40 g sample into high-speed blender. Add 100 mL  $\text{H}_2\text{O}$  (or more if necessary) and blend until homogeneous. Quant. transfer to 800 mL Kjeldahl flask with small portions  $\text{H}_2\text{O}$ . Continue as in (c), beginning "Add 200 g  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  . . ."

(c) *Semisolids and solid-liquid mixtures*.—Blend entire unit sample in high-speed blender to homogeneous mixt. Quant. transfer ca 50–60 g blended sample (accurately weighed) to 800 mL Kjeldahl flask with small portions  $\text{H}_2\text{O}$ , if necessary. Add 200 g  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  and 25 mL  $\text{H}_3\text{PO}_4$ . Wash down neck of flask with  $\text{H}_2\text{O}$  until total vol. is 350–375 mL. Steam distil sample directly into 1 L separator contg 50 mL NaOH soln (4 g/100 mL); collect 725–750 mL distillate in  $\geq 90$  min by adjusting transformers. (Distn rate is very critical; typical drop time is 50 drops/20 sec.) Rinse condenser with ca 20 mL  $\text{H}_2\text{O}$ . Acidify distillate to litmus with ca 20 mL HCl. Ext with one 100 mL and four 50 mL portions  $\text{CHCl}_3$ -ether (2+1). Shake each ext vigorously  $\geq 1$  min and collect exts in 600 mL beaker. Evap. combined exts carefully on steam bath, using gentle air current, to ca 25 mL, washing down sides of beaker occasionally with  $\text{CHCl}_3$ -ether. (Do not let exts go to dryness.) Transfer to 50 mL vol. flask, wash beaker with small portions  $\text{CHCl}_3$ -ether, and transfer washings to vol. flask. Dil. to vol. with  $\text{CHCl}_3$ -ether for TLC analysis.

**20.027****Determination**

Spot 100  $\mu\text{L}$  sample soln, using 50  $\mu\text{L}$  syringe twice, under gentle air draft on prepd plate. Also, spot 100  $\mu\text{L}$  benzoic acid std soln (50 mg/50 mL alcohol). Spot sample(s) and std ca 2.5 cm from bottom edge of plate and 4 cm apart, beginning 2.5 cm in from side edge. Place plate in chromatgc tank contg 250–300 mL mobile solv., *n*-hexane-HOAc (96+4), and develop chromatogram for 10 cm. Remove and air dry 5 min. Observe under UV shortwave radiation (2540Å). Sample and std benzoic acid appear as dark blue-purple spots on light fluorescent background. With pencil, circle spots 1 cm out from edge of each spot. (This gives exact location of each acid when plate is removed from radiation.) Scrape encircled area with steel spatula onto piece of Glassine paper and carefully transfer to 10 mL vol. flask. From unused portion of plate, scrape off area ca equal to that used for sample into 10 mL vol. flask to serve as blank. To each, add 7 mL alcohol, stopper, and shake 30 sec. Dil. to vol. with alcohol, transfer to centrf. tube, and centrf. until clear (ca 5 min) at high speed. Decant clear supernate into 5 cm micro cell and scan on recording spectrophtr from 310 to 250 nm against blank. Det. *A* of sample and *A'* of std at max. absorbance, ca 272 nm.

% Benzoic acid

$$= [(A/A') \times (\text{g std}/50 \text{ mL}) / (\text{g sample}/50 \text{ mL})] \times 100,$$

% Na benzoate = % benzoic acid  $\times 1.180$

**20.028****Qualitative Tests**

Evap. 2 mL portions  $\text{CHCl}_3$ -ether ext to dryness. On this residue, perform test for benzoic acid, 14.039, par. 4, beginning "From Mohr pipet, add . . ." and ending ". . . benzoic acid." Use 50 mL Pyrex test tube (25  $\times$  150 mm).

Det. IR spectrum. Evap. 5 mL  $\text{CHCl}_3$ -ether exts to dryness and make KBr disk with residue.

**BORIC ACID AND BORATES****20.029 Qualitative Test (9)—Official Final Action**

(a) *Preliminary test*.—Acidify sample with HCl (7 mL acid to each 100 mL sample). Heat solid or pasty samples with enough  $\text{H}_2\text{O}$  to make sufficiently fluid before acidifying. Immerse strip of turmeric paper, 20.033(a), in acidified liq., and let paper dry spontaneously. If  $\text{Na}_2\text{B}_4\text{O}_7$  or  $\text{H}_3\text{BO}_3$  is present, paper turns characteristic red, changed by  $\text{NH}_4\text{OH}$  to dark blue-green, but restored by acid.

(b) *Confirmatory test*.—Make ca 25 g sample decidedly alk. with lime- $\text{H}_2\text{O}$  or milk of lime and evap. to dryness on steam bath. Ignite dry residue at low red heat until org. matter is thoroly charred. Cool, digest with ca 15 mL  $\text{H}_2\text{O}$ , and add HCl dropwise until soln is distinctly acid. Immerse piece of turmeric paper in soln and dry without heat. In presence of  $\text{Na}_2\text{B}_4\text{O}_7$  or  $\text{H}_3\text{BO}_3$  color change will be same as in (a).

**Qualitative Thin Layer Test for Boron in Caviar (Screening Technique)(10)—Official Final Action****20.030****Reagents**

(a) *TLC plates*.—3  $\times$  1" microscopic slides coated with 250  $\mu\text{m}$  silica gel G (E. Merck).

(b) *Developing solvent*.—Anhyd. alcohol-benzene (1+10).

(c) *Spray reagents*.—(1)  $\text{NH}_4\text{OH}$ ; (2)  $\text{HOAc-H}_2\text{SO}_4$  (1+1).

(d) *Curcumin soln*.—0.125%. Dissolve 125 mg curcumin (available from Eastman Kodak Co.) in 100 mL HOAc. Prep. fresh daily.

**20.031****Preparation of Silica Gel Slides**

Clean slides with soap and rinse thoroly until they drain cleanly (without beading). Place slides on template, as shown in Fig. 20:02.

To make slides adhere to template, place 1 drop  $\text{H}_2\text{O}$  under each slide as it is set in place.

Weigh 30 g silica gel into 250 mL g-s erlenmeyer. Add 60 mL  $\text{H}_2\text{O}$  and agitate gently 45 sec. Pour quickly into Desaga-Brinkmann spreader set to give 250  $\mu\text{m}$  thickness. Pull applicator evenly over slides. Air dry slides 30 min. Place slides in oven 30 min at 100°.

**20.032****Determination**

(Caution: See 51.017.)

Put 10 mL developing solv. into 250 mL lipless beaker or suitable jar. Place filter paper wick (2.5  $\times$  8 cm) in solv., cover beaker with watch glass, and let equilibrate 5 min.

Place 100  $\pm$  20 mg caviar in mortar. Grind and ext with 20 mL  $\text{H}_2\text{O}$ . Transfer washings to g-s centrf. tube and centrf. 5 min. Decant supernate into 100 mL vol. flask. Add 10 mL  $\text{H}_2\text{O}$  to residue in tube, stopper, and shake vigorously 1 min. Centrf. and decant supernate into same vol. flask. Repeat with 10 mL  $\text{H}_2\text{O}$ , dil. to vol., and mix. Place 2 mL each of sample soln, std

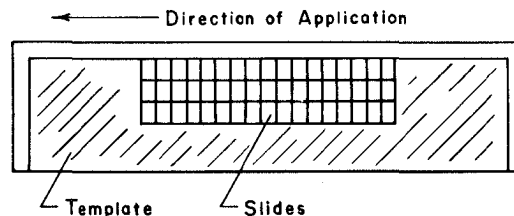

FIG. 20:02—Placement of slides on template for applying silica gel coating

soln, and H<sub>2</sub>O for blank in sep. Pt dishes. Add ca 6 drops 10% NaOH to each dish and swirl to mix thoroly. Evap. to chalk white dryness on vigorous steam bath (expose directly to steam). (Hot plate may be used; avoid spattering.) Dissolve residue in ca 1.5 mL 0.125% curcumin soln, applying gentle heat if necessary to dissolve residue. Add ca 1.5 mL HOAc-H<sub>2</sub>SO<sub>4</sub> soln (1+1), mix thoroly with stainless steel or plastic spatula, and let stand 15 min. Transfer solns to graduated beakers with absolute alcohol, dil. to 50 mL, and stir. Sep. spot 40  $\mu$ L blank, std soln, **20.039(e)(2)**, and sample soln on same slide. Place slide in beaker, cover, and let develop 10 min. Remove slide, air dry, and note red-purple spot at origin and excess curcumin dye above. Spray with spray reagent (7) and note blue color change in spot at origin. Respray with spray reagent (2) and note change to red-purple.

### Semiquantitative Method (17)—Official Final Action

(Applicable to meat)

#### 20.033

#### Reagents

(a) *Turmeric paper*.—Add 100 mL 80% alcohol to 1.5–2.0 g turmeric powder in 250 mL g-s erlenmeyer. Shake 5 min and filter. Dip sheets of Whatman No. 2 paper into the clear filtrate in flat-bottom dish (petri dish). Hang paper to dry. After 1 hr cut into 6 × 1 cm strips and store in tightly stoppered container protected from light.

(b) *Boric acid std soln*.—10 mg H<sub>3</sub>BO<sub>3</sub>/mL. Dissolve 1.000 g H<sub>3</sub>BO<sub>3</sub> in H<sub>2</sub>O and dil. to 100 mL.

#### 20.034

#### Preparation of Reference Standards

Transfer 0.00, 0.10, 0.20, 0.50, 0.75, 1.00, 2.50, and 5.00 mL std H<sub>3</sub>BO<sub>3</sub> soln to 15 mL test tubes. Dil. to 10 mL with H<sub>2</sub>O and add 0.7 mL HCl. Keep tubes tightly stoppered to prevent evapn. These stds represent 0.00, 0.02, 0.04, 0.10, 0.15, 0.20, 0.50, and 1.00% H<sub>3</sub>BO<sub>3</sub> in meat (based on 25 g sample extd with 50 mL H<sub>2</sub>O and 10 mL aliquot used for test). Std solns may be stored in Pyrex test tubes >6 months. On long storage, borate is leached from Pyrex.

#### 20.035

#### Determination

Disperse 25 g ground meat in 50 mL H<sub>2</sub>O in 125 mL erlenmeyer, using flat-end stirring rod. Cover with watch glass or small funnel. Bring to boil on hot plate (or over medium flame) with agitation. Do not overheat. Cool in ice bath or in beaker of H<sub>2</sub>O in refrigerator until fat solidifies (ca 0.5 hr). Filter thru pledget of glass wool. Transfer 10 mL filtrate to 15 mL test tube, add 0.7 mL HCl, stopper, and mix.

Mark identification on end of piece of turmeric paper and dip unmarked end into unknown soln to ½ the length of paper. Quickly remove moistened paper and place on sheet of white filter paper. Flat-tipped forceps are useful in handling paper.

Place freshly prepd std strips of test paper (made by dipping turmeric papers in similar manner into series of std solns) alongside sample turmeric strips.

After ≥1 hr (but <2 hr) at room temp., strips are dry enough for comparison. Good natural light is preferred. Place std strips ca 1 cm apart on white filter paper background and bring "unknown" sample strips between adjacent stds for close color matching. If color falls between 2 stds, est. value. Disregard streaks of color that may develop at edge of test strip.

If color intensity is beyond range of stds, repeat test with diln of meat filtrate (e.g., 5 mL filtrate, 5 mL H<sub>2</sub>O, 0.7 mL HCl and multiply final reading by 2). Use freshly prepd set of std papers with each series of samples tested.

### Quantitative Methods

#### 20.036 Titrimetric Method—Official Final Action

Make 10–100 g sample (depending upon material and amt of H<sub>3</sub>BO<sub>3</sub> present) distinctly alk. with 10% NaOH soln and evap. to dryness in Pt dish. Ignite until org. matter is thoroly charred, avoiding intense red heat; cool, digest with ca 20 mL hot H<sub>2</sub>O, and add HCl dropwise until reaction is distinctly acid. Filter into 100 mL vol. flask and wash with little hot H<sub>2</sub>O. (Vol. filtrate should be <50–60 mL.) Return filter contg any unoxidized C to Pt dish, make alk. by wetting thoroly with lime-H<sub>2</sub>O, dry on steam bath, and ignite to white ash.

Dissolve ash in few mL HCl (1+3) and add to liq. in 100 mL vol. flask, rinsing dish with few mL H<sub>2</sub>O. To combined solns add 0.5 g CaCl<sub>2</sub> and few drops phthln, then 10% NaOH soln until permanent light pink is produced. Finally dil. to vol. with lime-H<sub>2</sub>O, mix, and filter thru dry filter. To 50 mL filtrate add 1N H<sub>2</sub>SO<sub>4</sub> until pink disappears; then add Me orange, **6.005(g)**, and continue addn of acid until yellow changes to pink. Boil ca 1 min to expel CO<sub>2</sub>. Cool, and carefully add 0.2N NaOH until liq. becomes yellow, avoiding excess alkali. (All H<sub>3</sub>BO<sub>3</sub> is now in free state with no uncombined H<sub>2</sub>SO<sub>4</sub> present.) Add 1–2 g neut. mannitol and few drops phthln, read buret, and again titr. soln with the std NaOH until pink. Add little more mannitol, and if pink disappears, continue addn of the std alkali until pink reappears. Repeat alternate addn of mannitol and std alkali until permanent end point is reached. Vol. glycerol (neut. to phthln) equal to vol. soln to be titrd may be substituted for mannitol. 1 mL 0.2N NaOH = 0.0124 g H<sub>3</sub>BO<sub>3</sub>.

#### Spectrophotometric Method (10)—Official Final Action

(Applicable to caviar. Rinse all glassware with H<sub>2</sub>O before use. Carry reagent and caviar blanks thru detn with stds and samples. For caviar blank use caviar shown to be B-free by **20.032**.)

#### 20.037

#### Principle

B reacts with curcumin in nonaq. acid soln to form stable color complex. Intensity of color is measured spectrophtrically at 555 nm.

#### 20.038

#### Apparatus

(a) *Spectrophotometer*.—Beckman DK-2A ratio recording spectrophtr (superceded by model 5240) (or DU spectrophtr), or equiv., with silica 1 cm cells with g-s stoppers.

(b) *Platinum dishes*.—3 cm deep × 7 cm diam.

#### 20.039

#### Reagents

(a) *Curcumin soln*.—0.125%. See **20.030(d)**.

(b) *Sodium hydroxide soln*.—10%. Keep in plastic bottle.

(c) *Sulfuric acid-acetic acid*.—(1+1). Use new bottles of acids.

(d) *Anhydrous alcohol (used thruout method)*.—MeOH may be substituted. Let stand 24 hr over CaO, decant, and distil twice from KOH.

(e) *Boron std solns*.—(1) *Stock soln*.—100  $\mu$ g B/mL. Accurately weigh 57±3 mg H<sub>3</sub>BO<sub>3</sub>, ACS crystal, into 100 mL vol. flask. Add 50 mL H<sub>2</sub>O and shake mech. 20 min. Dil. to vol. and mix. (Prep. on day method is run.) (2) *Working soln*.—1  $\mu$ g B/mL. Pipet 1 mL stock soln into 100 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix.

#### 20.040

#### Preparation of Sample Solutions

Weigh 270±25 mg caviar into 250 mL 2-neck, r-b flask; place sample in exact center of bottom of flask. Connect flask to straight-tube H<sub>2</sub>O condenser to facilitate rinsing, and place condenser in center hole of flask and glass stopper in side hole.

(Do *not* use lubricating grease.) Add 1 mL  $\text{H}_2\text{SO}_4$ , close flask with glass stopper, apply small flame from Bunsen burner to circumference of acid soln, and heat until surface of liq. begins to move. Remove flame. Promote gentle evolution of bubbles with intermittent flame. Do not cause acid to spatter or to evolve copious fumes. Continue heating 5 min, or until solids are dissolved; soln will be black and smooth. Cool flask in ice- $\text{H}_2\text{O}$ . If fumes are present, let settle. With syringe, quickly add 1 mL 30%  $\text{H}_2\text{O}_2$  thru stoppered opening, close flask immediately, and gently heat soln with intermittent flame to initiate boiling. Heat ca 5 min, or until fumes start to evolve. (Soln should be generally clear with some minute particles.) Cool flask to room temp. in ice- $\text{H}_2\text{O}$ . Rinse condenser directly into reaction flask with  $\text{H}_2\text{O}$ . Disconnect flask, quant. transfer soln, using glass funnel, with  $\text{H}_2\text{O}$  into 100 mL vol. flask, dil. to vol., and mix. (Solns should be pale yellow or colorless.)

**20.041****Determination**

Pipet following into individual Pt dishes: 1 mL  $\text{H}_2\text{O}$  for reagent blank; 1, 2, 3, 4, and 5 mL working std soln; 1 mL caviar sample soln; 1 mL caviar blank soln (B-free). Add 1 mL 10% NaOH to each dish and swirl to mix thoroly. Place dishes on vigorous steam bath (expose directly to steam) and dry until chalk white (ca 2.5–3 hr). Transfer dishes to  $100 \pm 5^\circ$  oven and continue to dry residue 0.5 hr. (*Caution:* Higher temps will cause spattering.) Remove dishes and cool. Add 3 mL curcumin soln. Use individual spatula for each dish and stir residue with stainless steel or plastic spatula to dissolve. (All std residues will dissolve in 2–3 min, but sample soln does not dissolve completely and must be stirred 5 min. Very gentle heat may be applied to promote soln.) Cool dishes to room temp. and add 3 mL  $\text{HOAc-H}_2\text{SO}_4$  soln. Stir with same spatula to mix completely until no visible yellow color remains in dish or on spatula; continue to stir and rotate dish for 2 min after yellow color disappears. Let soln stand 15 min. Transfer solns with ca 50 mL anhyd. alcohol (eye dropper works well) to 100 mL vol. flasks, using glass funnels. Thoroly rinse dishes into flasks with anhyd. alcohol and dil. to vol. within 5 mL of mark. Treat each soln sep. as follows: Dil. to vol. and mix. Filter thru dry paper and discard first 3 mL. Collect filtrate directly in spectrophtr cells and read *A* against anhyd. alcohol at 700 and 555 nm.

Calc.  $\Delta A$  of std solns ( $A_{555} - A_{700}$ ). Subtract reagent blank  $\Delta A$  from std readings. Likewise, calc.  $\Delta A$  of caviar solns. Subtract caviar blank  $\Delta A$  from sample  $\Delta A$ . Plot std curve on graph paper:  $\mu\text{g B}/100 \text{ mL}$  as abscissa against  $\Delta A$  as ordinate. Det.  $\mu\text{g B}/100 \text{ mL}$  for caviar from graph.

$$\text{g B} = [\mu\text{g B}/100 \text{ mL (from graph)}]10^4$$

$$\% \text{ Boric acid} = (\text{g B} \times 5.7142 \times 100)/\text{g sample.}$$

★ **Atomic Absorption Spectrophotometric** ★  
**Method (12)—Official First Action**

**20.042****Apparatus**

*Atomic absorption spectrophotometer.*—Perkin-Elmer Model 303, or equiv. Typical operating parameters for this app. are given in Table 20:01. Operator must become familiar with optimum settings for his own app. and use table only as a guide. (*Caution:* See 51.006.)

**20.043****Reagents**

(a) *Extracting soln.*—20% (v/v) 2-ethyl-1,3-hexanediol in methyl isobutyl ketone. Sat. with  $\text{H}_2\text{O}$  by gently shaking soln

★ Surplus method—see inside front cover.

**Table 20:01 Operating Parameters**

Wavelength, Å	2497.7
Slit width, mm	1 (setting 3)
Source, ma	30
$\text{N}_2\text{O}$ flow rate, L/min	12 (scale divisions –6)
$\text{C}_2\text{H}_2$ rate, L/min	7 (metal ball scale divisions – 5.5)
Aspiration rate, mL/min	4
Scale expansion	3× or 10×
Noise suppression setting	2 or 3
Concn range, $\mu\text{g}/\text{mL}$	0–200

with  $\frac{1}{2}$  its vol.  $\text{H}_2\text{O}$  ca 1 min, letting sep. completely, and discarding aq. phase.

(b) *Boron std solns.*—(1) *Stock soln.*—1 mg B/mL. In 1 L vol. flask dissolve 5.716 g  $\text{H}_3\text{BO}_3$  in ca 500 mL  $\text{H}_2\text{O}$ , dil. to 1 L, and mix. (2) *Working solns.*—Pipet 10 mL stock soln into 100 mL vol. flask, dil. to vol., and mix. Pipet 5, 10, 15, and 20 mL portions this soln into sep. 50 mL g-s graduates, add 5 mL  $\text{H}_2\text{SO}_4$  to each, mix, cool, and dil. to  $30 \pm 3 \text{ mL}$  with  $\text{H}_2\text{O}$ . Pipet 10 mL extg soln, (a), into each, mix ca 1 min, and let phases sep. completely. Org. layers now contain 50, 100, 150, and 200  $\mu\text{g B}/\text{mL}$ , resp.

**20.044****Preparation of Sample**

(*Caution:* See 51.018 and 51.019.)

Accurately weigh ca 1 g sample into 150 mL  $\text{r-b}$  flask. Add 5 mL  $\text{H}_2\text{SO}_4$  and connect flask to  $\text{H}_2\text{O}$ -cooled condenser. Add 3 mL  $\text{HNO}_3$  thru top of condenser and heat mixt. with Bunsen flame to start reaction. Apply heat as necessary to maintain moderate reaction rate until most org. matter is destroyed and no brown fumes are evolved. If sample chars, remove flame, add 1 mL  $\text{HNO}_3$ , and resume heating. Repeat addn of 1 mL  $\text{HNO}_3$ , if necessary. Digestion is completed when no brown fumes are being evolved. (Total digestion time is ca 30 min and usually requires 3–4 mL  $\text{HNO}_3$ . Some fat may remain.) Cool, and rinse condenser with  $\text{H}_2\text{O}$  to bring total vol. in flask to  $30 \pm 3 \text{ mL}$ . Disconnect flask, pipet 10 mL extg soln into flask, stopper, and mix  $\geq 1 \text{ min}$ . Pour mixt. into 50 mL graduate and let phases sep. completely.

**20.045****Determination**

Set up app. as in Table 20:01, or use previously established optimum settings. Zero app. while aspirating extg soln, (a). Det. *A* of sample and stds in org. layer. Flush burner with extg soln, and check 0 point between readings. Det. B content from std curve of *A* against  $\mu\text{g B}/\text{mL}$ .

$\% \text{ H}_3\text{BO}_3 = [(\mu\text{g B}/\text{mL}) \times 10 \times 5.714]/(\text{g sample} \times 10^4)$ ,  
 where 5.714 is factor to convert B to  $\text{H}_3\text{BO}_3$ .

**Emission Spectroscopic Method (13)**  
**Official Final Action**

(Before proceeding with sample analysis, analyze known  $\text{H}_3\text{BO}_3$  soln until  $\geq 90\%$  recovery is obtained.)

**20.046****Apparatus**

(a) *Atomic absorption spectrophotometer.*—Operated in emission mode, Perkin-Elmer Model 403, or equiv. Operating parameters:  $\text{N}_2\text{O-H}$  flame with  $\text{N}_2\text{O}$  single-slot burner head; flow rates ca 12 L/min; wavelength 518 nm; spectral slit width 5 nm; equipped with strip chart recorder. (*Caution:* See 51.006.)

(b) *Digestion vessel.*—See 25.115.

**20.047****Reagents**

(a) *Chelating-extracting soln.*—15% (v/v) 2-Ethyl-1,3-hexanediol in methyl isobutyl ketone.

(b) *Boron std solns.*—(1) *Stock soln.*—500  $\mu\text{g}$  B/mL. In 1 L vol. flask, dissolve 2.858 g  $\text{H}_3\text{BO}_3$  in  $\text{H}_2\text{O}$ , dil. to vol., and mix. (2) *Working soln.*—150  $\mu\text{g}$  B/mL. Dil. 15.0 mL stock soln to 50.0 mL with  $\text{H}_2\text{O}$ .

**20.048****Preparation of Sample**

Accurately weigh ca 1 g well mixed sample into Teflon digestion vessel. Add 5.0 mL  $\text{HNO}_3$  and close vessel, tightening metal screw cap contg Teflon sealing disk. Similarly prep. blank, using 5.0 mL  $\text{HNO}_3$  only. Place vessel in  $150^\circ$  oven 1 hr. Remove vessel and let cool to room temp. Unscrew cap, snap on spout, and transfer digested sample with aid of 10 mL  $\text{H}_2\text{O}$  to Mojonnier flask (25 mL bulb capacity). (If Mojonnier flask is not available, 125 mL separator marked at 25 mL may be used.) Make soln just basic (litmus paper) by slowly adding  $\text{NH}_4\text{OH}$ ; usually ca 5 mL is required. Acidify by dropwise addn of  $\text{H}_2\text{SO}_4$  (1+1). For optimum extn, dil. contents of Mojonnier flask with  $\text{H}_2\text{O}$  to center of neck. Add 10 mL chelating-extg soln, stopper, and shake 1 min. Let phases sep. and decant upper org. layer into 25 mL vol. flask. Repeat chelation-extn with 10 and 5 mL chelating-extg soln, combining org. layers in vol. flask. Dil. to 25 mL with chelating-extg soln, stopper flask, and mix.

**20.049****Preparation of Standards**

Pipet 0, 1, 2, and 3 mL portions of B working std soln into sep. Mojonnier flasks (or separators, as for sample). Add 1–2 drops  $\text{H}_2\text{SO}_4$  (1+1) and dil. with  $\text{H}_2\text{O}$  to center of neck of flasks for optimum extns. Ext as for sample, beginning "Add 10 mL chelating-extg soln, . . ."

**20.050****Determination**

Using  $\text{N}_2\text{O}$  burner head,  $\text{N}_2\text{O}$ -H flame, and ca 5 nm spectral slit width, measure boron oxide molecular emission at 518 nm. Record signals on strip chart recorder. Suppress background signal, given by 0  $\mu\text{g}$  B std ext, to near 0 on chart, and control amplifier gain to give near full scale signal for highest B std. Aspirate 0  $\mu\text{g}$  B std soln between each sample or std reading. Measure each std and sample peak using 0  $\mu\text{g}$  B std as baseline. Plot std calibration curve and obtain amt B in sample from this curve.

**20.051 DIETHYLCARBONATE—OFFICIAL FINAL ACTION**

See 11.076–11.078.

**DEHYDROACETIC ACID****20.052 Qualitative Test (14)—Official Final Action**

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Salicylaldehyde reagent.*—Dissolve 10 mL salicylaldehyde in alcohol and dil. to 50 mL.

(b) *Test.*—Transfer dehydroacetic acid soln remaining in 500 mL vol. flask after quant. detn, 20.053, to 1 L separator. Add 100–125 mL ether and shake vigorously. Let sep., drain aq. layer, and discard. Drain ether into 125 mL erlenmeyer, taking care not to include any emulsion or  $\text{H}_2\text{O}$ . Evap. ether ext to dryness on steam bath and dissolve residue in 1 mL ca 0.5N NaOH. Pour alk. soln into test tube (do not rinse flask); add 0.5 mL of alc. salicylaldehyde soln and 1 mL NaOH (1+1). Mix, and place in boiling  $\text{H}_2\text{O}$  bath 5 min. Remove from bath, add 2 mL  $\text{H}_2\text{O}$ , and observe color. Include reagent blank and control contg 0.2 or 0.3 mg dehydroacetic acid for comparison. With  $\leq 10$  ppm dehydroacetic acid in cheese, red or orange soln is obtained. Intensity of color is approx. proportional to quantity of dehydroacetic acid present.

**Quantitative Method (14)—Official Final Action****20.053****Determination**

Weigh 50–60 g cheese to nearest 0.1 g, place in high-speed blender, and comminute (covered) with 80 mL  $\text{CHCl}_3$  3 min, scraping down walls and cover once during operation. Place filter paper on 6–8 cm diam. fritted glass buchner (if fritted glass funnel is not available, use ordinary buchner), transfer mixt. to funnel with spatula, and filter with suction. Return cake and paper to blender, add 80 mL  $\text{CHCl}_3$ , blend 1 min, and refilter into same flask. Use fresh paper for each filtration. Repeat extn and filtration for third time with 80 mL  $\text{CHCl}_3$ . Wash sides of filter and cake once with 25 mL  $\text{CHCl}_3$ . Remove greater portion of  $\text{CHCl}_3$  by compressing cheese cake.

Transfer combined  $\text{CHCl}_3$  filtrates to 500 mL separator. Rinse filter flask with 2 small portions  $\text{CHCl}_3$  and add to separator. Ext  $\text{CHCl}_3$  soln with ca 33 mL ca 0.5N NaOH. Transfer  $\text{CHCl}_3$  layer to 600 mL beaker and aq. layer to 300 mL erlenmeyer. Return  $\text{CHCl}_3$  to separator and repeat above alk. extn twice. Emulsion may be formed during extn, but most of it will break on standing. Transfer emulsified layer to alk. soln only in final extn. Acidify alk. ext with 70 mL ca 1N HCl, and rapidly aerate for such time as required to remove dissolved  $\text{CHCl}_3$  (5–10 min). To check complete removal of  $\text{CHCl}_3$ , smell top of flask while aerating. Be sure to remove all  $\text{CHCl}_3$  by aeration, or low values will be obtained. Filter soln thru medium or fine porosity fritted glass funnel fitted with filter paper and dil. to vol. with  $\text{H}_2\text{O}$  in 500 mL vol. flask. If soln is turbid, clarify by refiltering thru fine filter or asbestos pad.

Prep. reagent blank by extg 250 mL  $\text{CHCl}_3$  with alkali, adding acid to ext, aerating, and dilg to vol. with  $\text{H}_2\text{O}$ . Place portion of reagent blank in one cell and portion of sample soln in another. Det. A at 307 nm with Beckman DU spectrophtr, or equiv. Dil. sample soln if necessary to obtain readings in range of std curve. (Ordinary range of diln for A readings is from no diln to diln of 1 + 5.)

**20.054****Preparation of Standard Curve**

To prep. std curve use fresh dehydroacetic acid soln, as low readings are obtained from older solns. Weigh exactly 100 mg dehydroacetic acid (Eastman, or equiv.) and transfer to 100 mL vol. flask. Dissolve in ca 50 mL  $\text{H}_2\text{O}$  and 4 mL ca 0.5N NaOH. Dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 1.0, 3.0, and 5.0 mL (1.0, 3.0, and 5.0 mg dehydroacetic acid) aliquots of this stock soln into sep. 500 mL vol. flasks. To each add equiv. of ca 100 mL ca 0.5N NaOH and 70 mL ca 1N HCl, dil. to vol., and mix. Det. A at 307 nm, using reagent blank prepd as above. Plot A against mg dehydroacetic acid/500 mL prepd soln.

$\text{ppm Dehydroacetic acid} = (\text{mg}/500 \text{ mL}) \times 1000/\text{wt sample}.$

**SOLUBLE FLUORIDES****Qualitative Tests****20.055 Hydrofluoric Acid Test (15)—Official Final Action**

(a) *Not applicable in presence of silicates.*—After thoroly mixing sample, transfer to beaker 150 mL, or equiv. amt of aq. ext in case of solid foods, and boil, adding 5 mL 10%  $\text{K}_2\text{SO}_4$  soln and 10 mL 10%  $\text{Ba}(\text{OAc})_2$  soln. Collect ppt ( $\text{BaF}_2$ ) in compact mass (centrf. may be used advantageously) and wash on small filter. Transfer to Pt crucible and ignite.

Carefully dip cleaned glass plate, while hot, in mixt. of equal parts of *carnauba wax* and *paraffin*, and let cool. Make distinctive mark thru wax with sharp instrument, taking care not to scratch surface of glass.

Add few drops  $\text{H}_2\text{SO}_4$  to residue in crucible and cover crucible with waxed plate, having mark over center of crucible and making sure edge of crucible is in close contact with plate. Keep top surface of plate cool, and heat crucible 1 hr at as high temp. as practicable without melting wax (elec. stove gives most satisfactory form of heat). If fluorides are present, distinct etching is apparent on exposed glass.

(b) *Applicable in presence of silicates.*—Mix small amt of pptd  $\text{SiO}_2$  with pptd  $\text{BaF}_2$ , (a), and proceed as in 20.059 or 20.060. (This method is valuable for foods which contain considerable amt of  $\text{SiO}_2$  in the ash. Under these circumstances  $\text{H}_2\text{SO}_4$  liberates  $\text{SiF}_4$ , which would escape detection in (a).)

#### Quenching of Aluminum 8-Hydroxyquinolate Fluorescence (16)—Official First Action

##### 20.056

##### Reagents

(a) *Aluminum soln.*—Dissolve 2.22 g  $\text{AlNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 3 drops  $\text{HCl}$ , and dil. to 250 mL with  $\text{H}_2\text{O}$ .

(b) *Oxine reagent.*—Dissolve enough 8-hydroxyquinoline in 2N  $\text{HOAc}$  to make 5% soln. 1 mL of this soln is equiv. to ca 5 mL  $\text{Al}$  soln.

(c) *Ammonium acetate soln.*—Dissolve 77 g  $\text{NH}_4\text{OAc}$  in  $\text{H}_2\text{O}$  and dil. to 500 mL with  $\text{H}_2\text{O}$ .

(d) *Aluminum 8-hydroxyquinolate.*—Warm 250 mL  $\text{Al}$  soln to 50–60° and add excess of oxine reagent. Slowly add  $\text{NH}_4\text{OAc}$  soln until permanent ppt forms. Then add 20–25 mL more to ensure complete pptn. Let ppt settle and filter thru fritted glass crucible. Wash ppt well with at least seven or eight 30 mL portions cold  $\text{H}_2\text{O}$  and dry at 120–140°. Store in desiccator.

(e) *Chloroform soln of aluminum 8-hydroxyquinolate.*—Dissolve  $\text{Al}$  oxine in  $\text{CHCl}_3$  to prep. 0.5 mg/mL soln. Prep. daily.

(f) *Sulfuric acid.*—Concd. If blank detn reveals presence of  $\text{F}$ , purify as in 25.052(c), dilg and boiling 3 times.

##### 20.057

##### Test

Proceed as in 20.055(a), adding 3 mL  $\text{HOAc}$  to soln in addn to  $\text{K}_2\text{SO}_4$  and  $\text{Ba}(\text{OAc})_2$  solns. Transfer ignited residue to small porcelain crucible ( $\leq 5$  mL).

Wet piece of filter paper with  $\text{CHCl}_3$  soln of  $\text{Al}$  oxine in spot larger in diam. than top of crucible and let air dry. Add  $\text{H}_2\text{SO}_4$  to cover ash, crimp paper over crucible edge, and put wt (e.g., beaker) on paper. Heat crucible covered with paper 5 min at 50–60°. Observe paper under UV light. In presence of  $\text{F}$ , fluorescence of the  $\text{Al}$  oxine is quenched in area of spot over crucible. Limit of identification is ca 0.05 mg  $\text{F}$ . Conduct blank detn on  $\text{H}_2\text{SO}_4$ .

#### INSOLUBLE FLUORIDES—OFFICIAL FINAL ACTION

(Fluoborates, fluosilicates, etc.)

##### 20.058 Preparation of Sample

Make ca 200 g sample alk. with lime- $\text{H}_2\text{O}$ , evap. to dryness, and ash. Ext crude ash with  $\text{H}_2\text{O}$  contg enough  $\text{HOAc}$  to decompose carbonates; filter, ignite insol. portion, ext with  $\text{HOAc}$  (1+2), and again filter. Insol. portion now contains  $\text{CaSiO}_3$  and  $\text{CaF}_2$ , while filtrate contains all  $\text{H}_3\text{BO}_3$  present.

##### 20.059 Qualitative Test I (17)

Ash filter contg insol. portion from 20.058, mix with little pptd  $\text{SiO}_2$ , transfer to short test tube attached to small U-tube contg few drops  $\text{H}_2\text{O}$ , and add 1–2 mL  $\text{H}_2\text{SO}_4$ . Keep test tube in beaker of  $\text{H}_2\text{O}$  on steam bath 30–40 min. If any  $\text{F}$  is present,  $\text{SiF}_4$  generated is decomposed by  $\text{H}_2\text{O}$  in U-tube and forms gelatinous deposit on walls of tube.

Test filtrate for  $\text{H}_3\text{BO}_3$  as in 20.029. If both  $\text{HF}$  and  $\text{H}_3\text{BO}_3$  are present, it is probable that they are combined as  $\text{BF}_3$ . If, however,  $\text{SiF}_4$  is detected and  $\text{H}_3\text{BO}_3$  is not, repeat test without adding  $\text{SiO}_2$ , in which case formation of  $\text{SiO}_2$  skeleton is conclusive evidence of presence of fluosilicate. In ash contg appreciable amt of  $\text{SiO}_2$ ,  $\text{H}_2\text{SO}_4$  liberates  $\text{SiF}_4$  rather than  $\text{HF}$ . Therefore presence of fluosilicate, not fluoride, is indicated.

##### 20.060 Qualitative Test II

Ash filter contg insol. portion from 20.058 in Pt crucible, mix with little pptd  $\text{SiO}_2$ , and add 1 mL  $\text{H}_2\text{SO}_4$ . Cover crucible with watch glass from underside of which drop of  $\text{H}_2\text{O}$  is suspended, and heat 1 hr at 70–80°, keeping watch glass well cooled. The  $\text{H}_2\text{O}$  decomposes  $\text{SiF}_4$  formed, leaving gelatinous deposit of  $\text{SiO}_2$  and etching ring at periphery of drop of  $\text{H}_2\text{O}$ . Test filtrate for  $\text{H}_3\text{BO}_3$  as in 20.029.

##### 20.061 Quantitative Method

See 25.049–25.055.

#### FORMALDEHYDE

(See also 31.189–31.194.)

##### 20.062 Preparation of Sample—Official First Action

If sample is solid or semisolid, macerate 100 g with 100 mL  $\text{H}_2\text{O}$  in mortar. Transfer to 800 mL Kjeldahl flask, acidify with  $\text{H}_3\text{PO}_4$ , add 1 mL excess, connect with condenser thru trap, and slowly distil 50 mL. For milk, dil. 100 mL with 100 mL  $\text{H}_2\text{O}$ , and acidify and distil as for solids. With other liq. foods, acidify 200 mL and distil as for solids.

#### Qualitative Tests—Official First Action

##### 20.063 Chromotropic Acid Test (18)

(a) *Reagent.*—Prep. satd soln of 1,8-dihydroxynaphthalene-3,6-disulfonic acid (ca 500 mg/100 mL) in ca 72%  $\text{H}_2\text{SO}_4$  (pour 150 mL  $\text{H}_2\text{SO}_4$  into 100 mL  $\text{H}_2\text{O}$  and cool). Soln is light straw-colored.

(b) *Test.*—Place 5 mL reagent in test tube and add, with mixing, 1 mL distillate, 20.062. Place in boiling  $\text{H}_2\text{O}$  bath 15 min, and observe during heating period. Presence of  $\text{HCHO}$  is indicated by appearance of light to deep purple (depth of color depending on amt of  $\text{HCHO}$  present).

##### 20.064 Hehner-Fulton Test (19)

(Caution: See 51.030 and 51.047.)

(a) *Oxidizing soln.*—To cold  $\text{H}_2\text{SO}_4$  add, in small portions, equal vol. satd  $\text{Br-H}_2\text{O}$ , cooling thruout operation.

(b) *Test.*—To 6 mL cold  $\text{H}_2\text{SO}_4$  add 5 mL distillate, 20.062, slowly and with cooling. Place 5 mL mixt. in test tube, and add, slowly and with cooling, 1 mL aldehyde-free milk, then 0.5 mL oxidizing soln. Mix. Purplish-pink indicates  $\text{HCHO}$ .

##### 20.065 FORMIC ACID—OFFICIAL FINAL ACTION

See 18.050–18.055; 17.043–17.047.

#### HYDROGEN PEROXIDE

##### 20.066 Qualitative Test (20)—Official Final Action

(Applicable to milk)

(a) *Reagent.*—Dissolve 1 g  $\text{V}_2\text{O}_5$  in 100 mL  $\text{H}_2\text{SO}_4$  (6+94).

(b) *Test.*—Add 10–20 drops reagent to ca 10 mL sample and mix. Pink or red indicates  $\text{H}_2\text{O}_2$ .

**MONOCHLOROACETIC ACID (21)  
OFFICIAL FINAL ACTION**

**Qualitative Tests**

**20.067 Optical-Crystallographic Properties  
of Barium Salt**

(Applicable to com. preservatives)

Dil. 4–5 mL sample to 100 mL, add 6 mL  $\text{H}_2\text{SO}_4$  (1+1), and ext with equal vol. ether in separator. If emulsions form, ext in continuous extractor 1 hr. Transfer ether ext to separator, add few drops phthln and 5 mL 0.1N  $\text{Ba}(\text{OH})_2$ , and shake 30 sec. If aq. layer takes on pink typical of phthln, filter thru paper into small beaker. Add ca 0.05N HOAc until colorless and evap. to 1–2 mL on steam bath. Let remaining liq. evap. spontaneously in air and finally in desiccator. If 5 mL 0.1N  $\text{Ba}(\text{OH})_2$  does not give pink aq. layer, add 5 mL more before sepg. Repeat extn with  $\text{Ba}(\text{OH})_2$  soln several times or until pink soln is obtained, evapg each Ba soln in sep. beaker. Examine crystals under polarizing microscope.

Barium monochloroacetate monohydrate crystallizes from  $\text{H}_2\text{O}$  in plates, many of which are hexagonal in habit and frequently form in overlapping layers. Even in material that has been finely powd for microscopic examination, pointed terminations of the plates, often in pairs, can be observed. In parallel polarized light (crossed nicols) extinction is parallel and sign of elongation is neg. on more elongated plates. Plates invariably extinguish sharply with crossed nicols and therefore interference figures are not observed in convergent polarized light (crossed nicols). Since plates persistently lie in one orientation, significant refractive indices are detd by statistical method, lowest and highest indices resp. being measured on plates showing max. double refraction. These 2 indices are therefore arbitrarily designated as  $n_\alpha$  (min. value) and  $n_\gamma$  (max. value). Two significant refractive indices are:  $n_\alpha = 1.582$  and  $n_\gamma = 1.611$ , both  $\pm 0.002$ , frequently shown on the platey fragments.

**20.068 Indigo Test**

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Commercial preservatives*.—Dil. 2 mL sample to 100 mL, add 3 mL  $\text{H}_2\text{SO}_4$ , and shake with 100 mL ether. Add 3 mL *anthranilic acid reagent* (1 g + 0.3 g NaOH/50 mL) to ether ext, evap. at low temp., filter off any insol. matter, and proceed as in (c), beginning "Test with litmus paper."

(b) *Carbonated beverages, orange juice, and wine*.—Acidify 100 mL sample with 3 mL  $\text{H}_2\text{SO}_4$  and ext, using either continuous extractor or separator. Add 3 mL *anthranilic acid reagent*, (a), to ether ext and evap. at low temp. If any insol. matter seps, filter thru small wet paper. To clear liq. in 50 mL beaker add 30 mg  $\text{Na}_2\text{CO}_3$  and proceed as in (c), beginning "Test with litmus paper."

(c) *Barium monochloroacetate*.—Dissolve 0.17 g Ba salt, 20.067, in 5 mL  $\text{H}_2\text{O}$  in 10 mL graduate, add 1.05 mL 0.1N  $\text{H}_2\text{SO}_4$ , dil. to 10 mL, and mix. Let stand until ppt settles, or filter. Pipet 3 mL clear liq. into small beaker; add 2 mL *anthranilic acid reagent*, (a), and 30 mg  $\text{Na}_2\text{CO}_3$  (weighed). Test with litmus paper. If acid, add addnl 30 mg  $\text{Na}_2\text{CO}_3$ . Pour mixt. into test tube and heat 30 min in  $\text{H}_2\text{O}$  bath. Place tube in oven at  $125 \pm 5^\circ$  until only moist residue remains. Remove tube from oven, and drop 2 drops NaOH soln (1+1) directly upon residue. (If residue is entirely dry, add 1–2 drops  $\text{H}_2\text{O}$  and let stand until absorbed before adding NaOH soln.)

Return to oven until completely dry ( $\geq 1$  hr); then remove from oven and heat test tube at  $310\text{--}320^\circ$  until contents become orange. (This requires 15 sec to 2 min, but must be carefully

watched and tube removed from heat as soon as reaction is complete.) Cool slightly; add 5–7 mL  $\text{H}_2\text{O}$  from wash bottle, splashing  $\text{H}_2\text{O}$  to incorporate air into it. Warm over flame and blow air thru soln 1–2 min, using pipet or glass tube. Heat to bp over flame and again blow air thru soln. (As oxidn progresses, soln turns red if monochloroacetic acid is present, then green or blue or combination of two, and finally solid particles of indigo sep. out. These tend to rise to surface at first.) Let mixt. stand ca 10 min; then acidify slightly with HCl (1+1). Let stand 30 min more, filter, and wash pptd indigo with  $\text{H}_2\text{O}$  to remove acid. Let paper dry in air and preserve as exhibit.

*Note:* For fusion at  $310\text{--}320^\circ$  use brass block having one well to contain test tube and second well to contain thermometer. Wrap block with coil of nichrome wire and control temp. by variable voltage transformer. Furnaces, microburners, Wood's metal, solder baths, etc., may be used for fusion with equal success.

**20.069 Pyridine Test**

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Commercial preservatives*.—Ext 2 mL sample as in 20.068(a). Transfer ether ext to separator and add small piece of universal indicator paper and enough satd  $\text{NaHCO}_3$  soln (ca 5 mL) to make aq. layer alk. (pH 7–8) after vigorous shaking. Add enough  $\text{H}_2\text{O}$  to make total vol. of aq. layer ca 10 mL, and shake again. Drain aq. layer into small separator, wash ether with two 5 mL portions  $\text{H}_2\text{O}$ , and add washings to original aq. layer. Wash combined aq. exts once with 5–10 mL ether and discard ether; then add ca 1 mL  $\text{H}_2\text{SO}_4$  (1+1) in excess of vol. required to neutze alk. soln (ca 1.5 mL), and ext acidified soln with two 25 mL portions ether. Wash combined ether exts once with 1–2 mL  $\text{H}_2\text{O}$  and let ether soln stand few min after draining most of  $\text{H}_2\text{O}$  and swirling to get as complete sepn of  $\text{H}_2\text{O}$  from ether as possible. Pour ether thru folded paper into 200 mL flask, and wash separator and paper with two 10 mL portions ether.

To ether filtrate add 0.5 mL pyridine and small glass beads, mix, and evap. on steam bath to 2–3 mL. Transfer immediately with eye dropper to 15 mL centr. tube, and wash flask successively with 2, 1, and 1 mL portions ether. Evap. liq. in tube to ca 0.3 mL, add enough pyridine to increase vol. to ca 0.5 mL, and place in const temp. bath at  $60 \pm 2^\circ$ .

If crystals appear, test is pos. If they do not appear, remove tube from bath and evap. excess pyridine under reduced pressure. (Placing tube in beaker of hot  $\text{H}_2\text{O}$  hastens evapn.) When all liq. has been removed, add 0.5 mL pyridine, mix well, centr., and decant supernate. Add ca 5 mL ether to residue, shake well, centr., and decant. To residue add 1–3 mL absolute alcohol, varying amt of alcohol with amt of ppt, place tube in holder, and heat in hot  $\text{H}_2\text{O}$  or steam bath until ppt dissolves, being careful to swirl tube gently to avoid superheating and to boil alcohol so slowly that no loss occurs. Cool in ice bath, add ca 10 mL ether, mix well, and let stand in ice bath ca 5 min. Centr., decant supernate, and wash ppt once with ca 5 mL ether. If tube now contains crystals of pyridine betaine, test is pos.

(b) *Carbonated beverages, orange juice, and wine*.—Acidify 100 mL sample with 3 mL  $\text{H}_2\text{SO}_4$  and ext with ether, using either continuous extractor or separator. Continue as in (a), beginning "Transfer ether ext ..."

**Quantitative Method**

(Applicable to carbonated beverages, fruit juices, and wine)

**20.070**

**Apparatus**

*Continuous extractor similar to Fig. 12:01B*.—Outer part is made from 43 mm tubing, 45 cm long, with side tube, 25 cm

above bottom, fitted with drip tip,  $\frac{3}{8}$  24/40 joint. Inner tube is made from 12 mm tubing 40 cm long. Receiver is 250 mL conical flask with  $\frac{3}{8}$  neck to fit side tube.

**20.071****Reagents**

(a) *Silver nitrate soln.*—Dissolve 9 g  $\text{AgNO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L. 1 mL = ca 5 mg  $\text{CH}_2\text{ClCOOH}$ .

(b) *Ammonium thiocyanate std soln.*—1 mL = ca 5 mg  $\text{CH}_2\text{ClCOOH}$ . Dissolve 4.03 g  $\text{NH}_4\text{SCN}$  in  $\text{H}_2\text{O}$  and dil. to 1 L. Stdze against pure  $\text{NaCl}$  soln, 3.093 g/L, which contains 1.876 g Cl (equiv. to 5 g monochloroacetic acid)/L.

(c) *Ferric indicator.*—Satd soln of  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ .

**20.072****Determination**

(Caution: See 51.011, 51.039, and 51.054.)

In outer part of continuous extractor place vol. sample ( $\leq 150$  mL) contg 50–100 mg  $\text{CH}_2\text{ClCOOH}$ . (With com. preservatives, make preliminary diln to permit convenient measurement of proper size aliquot.) If necessary, dil. to 150 mL, add 3–5 mL  $\text{H}_2\text{SO}_4$ , mix, and ext with ether 2–3 hr. (Extn time for particular app. should be established by detg time required to ext  $\geq 95\%$  of known amt of  $\text{CH}_2\text{ClCOOH}$ .)

Tilt extractor so as to drain as much ether as possible into flask. Disconnect flask, add 25 mL 1N  $\text{NaOH}$  in excess of that required to make aq. layer alk. to litmus paper after shaking, shake, and evap. ether on steam bath to ca 25 mL, hastening process by passing air current into mouth of flask. Digest on steam bath 2 hr or boil under reflux condenser 30 min.

Add 50 mL  $\text{H}_2\text{O}$ , 15 mL  $\text{HNO}_3$ , and known vol. of the  $\text{AgNO}_3$  soln in excess. Shake 0.5–1 min, add ferric indicator, and titr. excess Ag with the  $\text{NH}_4\text{SCN}$  soln. In titrn, carefully add  $\text{NH}_4\text{SCN}$  soln until pink formed fades slowly on mixing; shake soln ca 30 sec and filter thru folded paper into second flask. When first flask is empty, wash down walls with ca 50 mL  $\text{H}_2\text{O}$  and add this to filter after all soln has passed thru. When wash  $\text{H}_2\text{O}$  has passed thru, complete titrn. Similarly titr. vol.  $\text{AgNO}_3$  soln equal to that added to sample. Difference between 2 titrns is measure of  $\text{CH}_2\text{ClCOOH}$ .

Instead of using the continuous extractor,  $\text{CH}_2\text{ClCOOH}$  may be extd equally efficiently (except with orange juice) as follows: To 100 mL sample add 3 mL  $\text{H}_2\text{SO}_4$  and shake in separator with three 100 mL portions ether. Combine ether exts and wash by shaking with two 30 mL portions 1N  $\text{NaOH}$ . Combine the two  $\text{NaOH}$  solns and digest as above.

**NITRITES (22)—OFFICIAL FIRST ACTION**

(Applicable to dry cure mix or curing pickle)

**20.073****Apparatus**

Bend piece of glass tubing 250 mm long, 6 mm od, to form right angle ca 60–70 mm from one end. Connect short end with rubber tube to outlet of pressure regulator on  $\text{CO}_2$  tank.

**20.074****Preparation of Sample**

(a) *Dry cure mix.*—Weigh 50.0 g sample and dissolve in 1 L  $\text{H}_2\text{O}$ . Transfer 25 mL aliquot to 250 mL erlenmeyer.

(b) *Pickle soln.*—Filter thru dry paper. Weigh 50.0 g filtrate into 250 mL erlenmeyer.

**20.075****Determination**

To soln in flask, add 20 mL colorless 15%  $\text{KI}$  soln and ca 2 mL starch soln, 32.065(g). Insert long end of gas inlet tube and adjust flow of  $\text{CO}_2$  to ca 5 bubbles/sec.

After ca 5 min, raise  $\text{CO}_2$  delivery tube to just above surface of liq., add 20 mL  $\text{H}_2\text{SO}_4$  (1+7) from buret, and mix thoroly. Titr. with std 0.0725N  $\text{Na}_2\text{S}_2\text{O}_3$ , with  $\text{CO}_2$  flowing, to first complete disappearance of starch-I color. 1 mL 0.0725N  $\text{Na}_2\text{S}_2\text{O}_3$  = 0.0050 g  $\text{NaNO}_2$ .

**20.076 PROPIONATES (MOLD INHIBITORS)**

See 14.094–14.101.

**QUATERNARY AMMONIUM COMPOUNDS (QAC)****Qualitative Tests****20.077 Bromophenol Blue Method (23)****Official First Action**

(Applicable to milk. Note precautions of 20.084–20.089. Caution: See 51.011, 51.039, and 51.046.)

Pipet 25 mL milk into 250 mL vol. flask contg 10 mg bromophenol blue, 20.085(d), and agitate until solid reagent dissolves. Gradually add 50 mL acetone with shaking; then add, dropwise, enough  $\text{HCl}$  (1+1) to produce bright yellow in mixt. (ca 1 mL); then add 0.2–0.3 mL excess. Gradually, with continuous mixing, dil. to vol. with acetone. Mix, let stand 30 min, and filter thru folded paper.

Measure 200 mL filtrate in graduate and pour into 500 mL separator; fill graduate to 200 mL with  $\text{H}_2\text{O}$  and add to separator. Wash aq. acetone mixt. by shaking with three 50 mL portions pet ether. When sepd, pour each portion of pet ether thru filter paper and reserve paper for filtration of ethylene chloride ( $\text{CH}_2\text{ClCH}_2\text{Cl}$ ) ext later. Evap. aq. acetone soln on steam bath under air current until vol. is reduced to  $\leq 100$  mL and acetone odor is gone. Cool, transfer to 250 mL separator with  $\text{H}_2\text{O}$  (reserve beaker), and add 5 mL  $\text{HCl}$  (1+1).

Pipet 50 mL  $\text{CH}_2\text{ClCH}_2\text{Cl}$  into separator and shake 1–2 min. Drain lower layer into beaker used for evapn in such manner as to wash down sides and return this liq. to separator, washing beaker with little  $\text{H}_2\text{O}$ . Again shake 2–3 min, let stand until clear, and drain lower layer thru paper reserved above into 125 mL separator contg 10 mL 1%  $\text{Na}_2\text{CO}_3$  soln. Stopper, invert separator, and shake carefully 2–3 min, using rotary motion. Reverse funnel to normal position and let stand to sep. Top layer will be usual purple of alk. soln of strong bromophenol blue; blue lower layer is pos. test for QAC. To better observe color, drain lower layer into g-s flask contg 1–2 g anhyd. granular (not powd)  $\text{Na}_2\text{SO}_4$ , which will absorb on contact any drops of purple soln that may unavoidably enter flask. Decant  $\text{CH}_2\text{ClCH}_2\text{Cl}$  layer into another vessel, if necessary, to avoid any color reflected from colored salt in flask. Solv. layer must not be filtered, since most papers contain enough residual acid to change the bromophenol blue-QAC complex from blue to practically invisible yellow.

**20.078 Optical-Crystallographic Properties of the Reineckates (24)—Procedure**

Use reineckate salt obtained in 20.083 or proceed as follows: Add excess of  $\text{NH}_4$  reineckate to aq. soln of QAC and stir. In most cases, if  $>20$  mg QAC is present, ppt forms at once. With smaller amts, let soln stand at room temp.  $\geq 30$  min and then stir 1–2 min. Let mixt. stand several hr, filter thru fine porosity fritted glass crucible, and wash several times with  $\text{H}_2\text{O}$ . Dry ppt with suction, dissolve thru filter with acetone, and evap. off acetone. Dissolve dry residue by warming with min. amt alcohol. If considerable amt of ppt is used, crystals deposit on cooling. Filter thru fritted glass crucible and dry by suction. With  $<30$  mg ppt, dissolve in 10 mL alcohol and let solv. evap. on warm, but not hot, surface with aid of gentle current of air.

**Table 20:02 Optical-crystallographic properties of reineckates of quaternary ammonium compounds**

Compound	Quant. Factor (Anhyd.)	Refractive Indices <sup>a</sup>			Optic Sign	Extinction <sup>b</sup>	Elongation	Habit
		$\alpha$	$\beta$	$\gamma$				
Cetyltrimethylbenzylammonium Reineckate (Zettyn®)	0.5834	1.572	1.651	1.660	—	i, s	—	Rhomboid plates
Alkyldimethylbenzylammonium Reineckate	0.5579	1.576	—	1.651	—	s	—	Rhomboid plates

<sup>a</sup> Refractive indices  $\pm 0.003$ , at 24–26°; <sup>i</sup> = intermediate index.<sup>b</sup> Extinction: p = parallel; i = inclined; s = symmetrical.

Det. optical-crystallographic properties of the crystals as in 36.108 and compare with those listed in Table 20:02 or with those detd on crystals obtained from known QAC compds.

**Quantitative Methods****Ferricyanide Method (23)—Official Final Action**

(Applicable to com. preservatives)

**20.079****Reagents**

(a) *Acetate buffer soln.*—Dissolve 130 g NaOAc·3H<sub>2</sub>O in H<sub>2</sub>O, add 42 mL HOAc, and dil. to 500 mL.

(b) *Ferricyanide soln.*—Dissolve 6.6 g K<sub>3</sub>Fe(CN)<sub>6</sub> in H<sub>2</sub>O and dil. to 1 L.

(c) *Zinc sulfate soln.*—Dissolve 20 g ZnSO<sub>4</sub>·7H<sub>2</sub>O in 180 mL H<sub>2</sub>O.

(d) *Thiosulfate std soln.*—0.02N. Prep. daily by dilg 0.1N soln, 50.037–50.038. 1 mL 0.02N soln = 0.02142 g alkyldimethylbenzylammonium chloride, MW 357.

**20.080****Determination**

Det. approx. QAC concn as follows: Pipet 1 mL buffer soln, 2 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln, and 20 mL H<sub>2</sub>O into each of 4 small erlenmeyers. To these flasks add 0.5, 1.0, 2.0, and 4.0 mL, resp., of sample, mix, and filter. Add 2 mL addnl sample to each filtrate, mix, and compare results with table, 20.081.

Into 100 mL Kohlrausch flask, pipet aliquot of sample contg ca 0.5 g QAC, as indicated by 20.081, dil. if necessary to 50 mL, add 5 mL buffer soln, and mix. Add 30 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln from pipet while swirling flask. Dil. to 100 mL with H<sub>2</sub>O and mix. After 30 min, filter, discarding first 10–15 mL filtrate. Pipet 50 mL filtrate into 500 mL erlenmeyer, and add 100 mL H<sub>2</sub>O and 1–2 g KI. Rotate flask until salt dissolves, add 10 mL HCl (1+1), mix, and let stand 2 min. Add 10 mL ZnSO<sub>4</sub> soln, mix, and titr. with 0.02N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, adding starch indicator, 6.005(f), when color fades to tinge of yellow. Make blank detn including all of above operations but substituting H<sub>2</sub>O for sample. Calc. QAC content from difference in 2 titrns.

If sample contains ca 0.5 g QAC/100 mL, instead of proceeding as above, pipet 100 mL sample into 200 mL vol. flask, add 10 mL buffer soln and 30 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln, dil. to vol. with H<sub>2</sub>O,

mix, let stand 30 min, filter, and titr. 100 or 150 mL aliquot filtrate as above.

**20.081****Approximation of Content of Alkyldimethylbenzylammonium Chloride (MW 357)**

Quaternary Ammonium Chloride, %	Sample Added			
	A 0.5 mL	B 1.0 mL	C 2.0 mL	D 4.0 mL
≥ 8.4	No ppt	No ppt	No ppt	No ppt
5	Ppt	No ppt	No ppt	No ppt
2.5	Ppt	Ppt	No ppt	No ppt
1.25	Ppt	Ppt	Ppt	No ppt
≤ 1	Ppt	Ppt	Ppt	Ppt

**Reineckate Method (25)—Official Final Action**

(Applicable to preservatives, tinctures, and isotonic solns)

**20.082****Reagent**

*Reineckate reagent.*—Place 0.75 g NH<sub>4</sub> reineckate (NH<sub>4</sub>[Cr(NH<sub>3</sub>)<sub>2</sub>(SCN)<sub>4</sub>].H<sub>2</sub>O; MW = 354.47) in 125 mL erlenmeyer, add 50 mL H<sub>2</sub>O, stopper, shake ca 2 min, and filter.

**20.083****Determination**

Place 100 mL sample contg 10–100 mg QAC in 250 mL beaker; add, with stirring, 5 mL portions reineckate reagent until liq. is bright pink. Let stand 30 min and add more reagent unless supernate is deep pink. Stir again 1–2 min. After several hr, filter thru fine porosity fritted glass crucible, and wash beaker and filter with at least three 15 mL portions H<sub>2</sub>O. (It is unnecessary to transfer all ppt to crucible.) Wash down sides of crucible with H<sub>2</sub>O and dry by suction. If ppt forms cake in filter, mix with the wash H<sub>2</sub>O with stirring rod used before.

Dissolve reineckate salt in acetone as follows: Set up suction app. to fit glass crucible, using as receiver side-arm test tube for application of suction. With 5 mL pipet, wash down sides of beaker used for pptn and add this liq. to crucible. Rinse beaker second time and add to liq. in crucible. Stir to dissolve and draw liq. thru with suction. Wash out beaker third time and wash

down sides of crucible several times with small portions of acetone. When liq. passing thru is colorless, disconnect, and wash into test tube with acetone any pink material which may have dried on bottom or outside of crucible or on inside of funnel. Discard small amt of greenish solid in crucible due to impurities and decomposition products of reagent.

Transfer acetone soln to tared beaker (50 mL beaker for  $\leq 20$  mg QAC and 100 mL beaker for  $> 20$  mg) and evap. on warm (but not hot) surface. If few drops of moisture remain, pass gentle air current into beaker until it appears dry. Dissolve residue by warming in 10 mL alcohol (or more, if needed); let solv. evap. spontaneously, dry in desiccator, and weigh. Wt QAC = factor (Table 20.02)  $\times$  wt ppt. Ppt may be used for detn of optical-crystallographic properties, Table 20.02.

(To remove greenish solid from crucible, add 10–12 mL HCl (1+1) and stir to dissolve. Draw liq. thru by suction and wash several times with  $H_2O$ . Reverse crucible and wash by filling bottom cavity with solv. Use 2 fillings each of  $H_2O$ , alcohol,  $H_2O$ , acetone, and  $H_2O$  in order given.)

#### **Bromophenol Blue Method (23)—Official Final Action**

(Precaution: Have all glassware scrupulously clean, and especially avoid soap, since reaction occurs between soap and QAC. If soap is used in cleansing, rinse all glassware with  $H_2O$ , and as extra precaution, rinse all pipets with alcohol and dry by suction.)

#### **20.084**

#### **Apparatus**

*Steam distillation apparatus.*—See 18.050(a) for generator. Use 500 mL or 1 L distn flask, fitted with spray tube, 12.025(c), reaching to within 1 or 2 cm of bottom of flask (all connections & joints), and with stopper for steam inlet (to be used during early part of distn). Suitable app. is described in 19.133.

#### **20.085**

#### **Reagents**

(a) *Sodium carbonate soln.*—Dissolve 5 g  $Na_2CO_3$  in 500 mL  $H_2O$ .

(b) *Sodium sulfate.*—Anhyd. granular (not powd). (Mallinckrodt A.R. granular grade is satisfactory.)

(c) *D.C. 12.*—Lauryldimethylbenzylammonium chloride, or other solid QAC.

(d) *Bromophenol blue soln.*—Dissolve 40 mg tetrabromophenolsulfonphthalein in warm  $H_2O$ , cool, and dil. to 100 mL.

Bromophenol blue should pass following test for purity: Place 20 mg bromophenol blue in 125 mL separator; add 50 mL  $CH_2ClCH_2Cl$  and 5 mL 1%  $Na_2CO_3$  soln, and shake until dissolved. Let stand until mixt. seps into 2 layers. Lower layer should be colorless; upper layer purple. Add 10 mL soln contg 0.1 mg D.C. 12 or other QAC, shake again, and let sep. Lower layer should be clear blue. Drain lower layer and examine in spectrophtr. Absorption peak should be at ca 608 nm. Compare absorption curve with that of sample purified as in 20.086. If test gives yellow or green soln or if absorption curve is essentially different from that of purified sample, purify as in 20.086.

#### **20.086**

#### **Purification of Bromophenol Blue**

Place 2 g bromophenol blue in 400 mL beaker and dissolve in 25 mL 1%  $Na_2CO_3$  soln. Transfer to 1 L separator, using ca 300 mL  $H_2O$ . Add 500 mL  $CH_2ClCH_2Cl$  and shake. Add 1 mL soln contg 10 mg D.C. 12 or other QAC and shake until thoroly extd. If lower layer is yellow, repeat addn of D.C. 12 soln in 1 mL portions with shaking until upon sepn of the 2 layers, lower one has greenish tint. Drain lower layer and discard. Add 200 mL  $CH_2ClCH_2Cl$  and 1 mL D.C. 12 soln to separator and shake. This time lower layer should be clear blue. If layer is green, drain and repeat addn of  $CH_2ClCH_2Cl$  and D.C. 12 until blue soln is

obtained. Wash aq. layer with 100 mL portions  $CH_2ClCH_2Cl$  until lower layer is colorless or only faint blue. Acidify aq. layer with HCl and ext yellow ppt with  $CH_2ClCH_2Cl$  until aq. soln is only faint yellow. Distil off most of  $CH_2ClCH_2Cl$  and permit remainder to evap. spontaneously in beaker. Grind residual powder. Test portion for purity as in 20.085(d) and if suitable, use as reagent.

#### **20.087**

#### **Preparation of Standard Curve**

Stdze 1% soln QAC to be detd as in 20.080. (If this compd is not available, use any solid QAC of known composition such as D.C. 12, lauryldimethylbenzylammonium chloride. If necessary, prep. std soln from com. soln stdzd by ferricyanide method, 20.080.) By performing method below, det. max. and min. concns of this compd that produce, in 50 mL  $CH_2ClCH_2Cl$ , A at 610 nm suited to color-measuring instrument used. Prep. set of  $\geq 3$  stds contg, in 50 mL, amt of QAC covering range between these max. and min. concns, and plot curve as directed below. (If Beckman spectrophtr is used, 0.0, 0.1, 0.2, and 0.25 mg/50 mL are suitable stds.)

Pipet 50 mL of each std into separator; add 3 mL bromophenol blue soln, 1 mL HCl (1+1), and 50 mL  $CH_2ClCH_2Cl$ ; and shake 2–3 min. When clear, drain lower layer into another separator contg 10 mL  $Na_2CO_3$  soln, and shake 2–3 min. Let stand until clear, drain lower layer into g-s flask contg 1–2 g  $Na_2SO_4$ , and after 30 min read in instrument. (Use same or similar cell for all stds, and light filter centering at 610 nm.) Plot scale readings, if these are in terms of A or proportional to it, against concns used; if instrument reads in terms of T, convert readings to A before plotting.

#### **20.088**

#### **Preparation of Sample**

(a) *Bottled beverages containing fruit juices.*—Mix thoroly, and measure 50 mL sample into graduate. Filter on 7 cm buchner and dil. filtrate to 100 mL with  $H_2O$  (Soln I). Place filter paper in 400 mL beaker and ext with small portions of alcohol until no more color is extd and paper remains white. Transfer alc. ext to 500 mL distg flask; add 10 mg bromophenol blue, 2 mL HCl (1+1), and 100 mL  $H_2O$ . Steam distil and collect vol. distillate  $\geq 100$  mL greater than vol. alcohol in ext. Cool residue in distg flask, transfer to separator, wash with 40, 30, and 30 mL portions pet ether, and proceed as in 20.089.

Also take suitable aliquot of Soln I (first try 5 mL), transfer to separator, add 3 mL bromophenol blue soln and 1 mL HCl (1+1), and proceed as in 20.089.

(b) *Beer.*—Place 100 mL decarbonated beer, 10.001, in steam distn flask and add 10 mL bromophenol blue and 2 mL HCl (1+1). Steam distil and collect ca 200 mL distillate. Cool residue, transfer to separator, wash with 100 and 50 mL portions pet ether, and proceed as in 20.089.

(c) *Table sirup.*—Transfer 20 g sample to 100 mL vol. flask, dil. to vol. with  $H_2O$ , and mix thoroly. Pipet aliquot of soln into separator, add 5 mL bromophenol blue soln and 1 mL HCl (1+1), and proceed as in 20.089.

(d) *Eggs.*—Weigh  $12.5 \pm 0.25$  g well mixed sample in tared 50 mL beaker. Add 10 mL  $H_2O$ , mix well with rod, pour carefully into 250 mL vol. flask, and wash beaker with 5–10 mL more  $H_2O$ , adding washings to flask. While swirling flask, gradually add acetone, little at time, mixing constantly, until flask is filled to mark; stopper and invert several times. Let stand 10–15 min and filter thru folded paper (Whatman No. 12, 18.5 cm) into 250 mL graduate until 200 mL filtrate is obtained. Pour filtrate into 1 L separator, wash down sides of graduate with 25 mL acetone, and add to separator; fill graduate to 250 mL with  $H_2O$  and add to separator. Add 25 mL HCl (1+1) to separator and mix. Ext liq. in separator with pet ether, using 300, 250, 150, and 100 mL,

and shaking gently to prevent formation of emulsions. Transfer extd aq. layer to 600–800 mL beaker, add 2–3 glass beads, and evap. to 50–75 mL on steam bath.

After evapn, add 10 mg bromophenol blue and wash down sides of beaker with little H<sub>2</sub>O. When soln is cool, pipet 50 mL CH<sub>2</sub>ClCH<sub>2</sub>Cl into beaker, letting solv. flow down sides of beaker. Pour contents of beaker into 250 mL separator, washing out beaker with little H<sub>2</sub>O. Shake ca 1 min. Return liq. to beaker, letting it flow down sides of beaker. Again return liq. to separator and shake ca 2 min. Proceed as in 20.089, beginning "Let stand until clear, . . ."

**20.089****Determination**

Pipet 50 mL CH<sub>2</sub>ClCH<sub>2</sub>Cl into separator, 20.088(a), (b), or (c), and shake 3–4 min. Let stand until clear, drain lower layer into second separator contg 10 mL 1% Na<sub>2</sub>CO<sub>3</sub> soln, and shake 3–4 min. Let sep. and observe lower layer. If blue, quaternary base is present. Judge from depth of color whether or not it is suitable for reading in photometer. If color is suitable for reading without diln, dry by draining lower layer into g-s flask contg 1–2 g of the Na<sub>2</sub>SO<sub>4</sub>, let stand 30 min, transfer to suitable cell, and read color in instrument at 610 nm. Det. amt QAC present from std curve, 20.087, and calc. to mg/100 mL.

If color is too deep for direct reading, acidify contents of second separator with 1–2 mL HCl (1+1), shake until yellow, and return to first separator. Pipet second 50 mL portion CH<sub>2</sub>ClCH<sub>2</sub>Cl into first separator, shake 3–4 min, let stand until lower layer is clear, and drain lower layer into flask. (If sample is known to contain >1 mg QAC/100 mL, entire 100 mL CH<sub>2</sub>ClCH<sub>2</sub>Cl may be added at one time.)

Det. proper aliquot as follows: Pipet 5 mL into 125 mL separator, dil. with 25 mL CH<sub>2</sub>ClCH<sub>2</sub>Cl, add 10 mL 1% Na<sub>2</sub>CO<sub>3</sub> soln, and carefully shake 2 min. Let sep. and observe lower layer. If depth of color is suitable for reading, dil. to 50 mL by adding 20 mL CH<sub>2</sub>ClCH<sub>2</sub>Cl from pipet, shake 1 min, let settle, drain lower layer, dry as above, and read. If color is not deep enough, add addnl soln in 5 mL increments until suitable color is obtained, add solv. if necessary to total vol. of 50 mL, shake, drain, dry, and read in instrument.

When proper aliquot has been detd, check as follows: Pipet aliquot of CH<sub>2</sub>ClCH<sub>2</sub>Cl soln into 50 mL vol. flask, dil. to vol. with CH<sub>2</sub>ClCH<sub>2</sub>Cl, and pour into 125 mL separator. Pipet 10 mL 1% Na<sub>2</sub>CO<sub>3</sub> soln into vol. flask, swirl, pour into separator, and wash out vol. flask with 2–3 mL H<sub>2</sub>O from wash bottle. Shake, settle, drain, dry, and read, adding ca 5 mg dry bromophenol blue to separator if aliquot used was ≤10 mL.

For bottled beverages contg fruit juices, add amt of QAC found in residue to amt found in Soln I to obtain total amt in sample.

**Eosin Yellowish Method (26)—Official First Action**

(Applicable to aq. solns and milk)

**20.090****Apparatus**

(a) *Centrifuge*.—Clinical high-speed type fitted for 50 mL tubes. International No. 2 centrif. with head No. 241 at speed of 2500 rpm is also satisfactory.

(b) *Centrifuge tubes*.—Heavy-wall, 40 mL centrif. tubes, Pyrex, No. 8400, or equiv.

(c) *Test tubes*.—Pyrex, g-s, 15 × 150 mm.

**20.091****Reagents**

(a) *Acetylene tetrachloride*.—CHCl<sub>2</sub>CHCl<sub>2</sub>. (Caution: Toxic reagent. See 51.040.) Should give distinct pink lower layer after

sepn, when 5 mL is shaken 1 min with 2 mL buffer soln, (c), 0.5 mL eosin yellowish soln, (d), and 5 mL aq. soln contg 1 ppm Cetab, Dobenzyl chloride, Et Cetab, Hyamine 10-X, or laurylpyridinium chloride, or 2 ppm lauryldimethylbenzylammonium chloride. If reagent does not meet this test, distil under reduced pressure, rejecting first 10% of distillate and collecting ca 80% of vol. placed in distn flask.

(b) *Aerosol OT std solns*.—(1) *Stock soln*.—Prep. soln of dioctyl Na sulfosuccinate to contain 100 mg/100 mL. Det. strength as follows: Pipet 2 mL soln contg, in 100 mL, 100 mg QAC to be detd, into g-s test tube contg 2 mL CHCl<sub>2</sub>CHCl<sub>2</sub>, 2 mL buffer soln, and 0.5 mL eosin yellowish soln. Carefully add Aerosol OT soln from buret in small amts, violently shaking mixt. ≥30 sec after each addn until, after sepn into 2 layers, only light pink is noticeable when test tube is placed against white background. Continue addns in 0.01 or 0.02 mL portions until lower layer is no longer pink. (2) *Working soln*.—Dil. to 100 mL such vol. stock soln as will produce soln 1 mL of which is equiv. to 0.1 mg QAC to be detd. Stdze against std soln (1 mL = 0.1 mg) of QAC to be detd.

(c) *Citrate buffer soln*.—pH 4.5. Dissolve 25 g citric acid in 75 mL H<sub>2</sub>O and add enough 50% NaOH soln (ca 13 mL) to bring pH to 4.5.

(d) *Eosin yellowish soln*.—Dissolve 25 mg D&C Red No. 22 in H<sub>2</sub>O and dil. to 50 mL.

(e) *Lactic acid soln*.—50%. Add 41 g H<sub>2</sub>O to 59 g lactic acid, 85% reagent grade, and mix.

(f) *Sodium hydroxide soln*.—4M. Dissolve 32 g NaOH in H<sub>2</sub>O and dil. to 200 mL.

**20.092****Determination**

(a) *Milk*.—Pipet 15 mL CHCl<sub>2</sub>CHCl<sub>2</sub> (Caution: See 51.018) into centr. tube, add 6 mL lactic acid soln and 15 mL milk to be tested, stopper, and shake ca 3 min. Add 6 mL 4M NaOH and mix carefully until curd seps thruout mixt.; then shake ≥30 sec. Centrf. at high speed (ca 3200 rpm) 7 min. Decant serum and discard; puncture layer of curd at 2 points and drain CHCl<sub>2</sub>CHCl<sub>2</sub> ext into small beaker. Avoiding any drops of aq. soln, transfer 5 mL ext with pipet into g-s test tube contg 2 mL buffer soln and 0.5 mL eosin yellowish soln; stopper and shake ca 2 min. Let stand to sep. and observe color of lower layer. If color is faint, place against white background. If layer is pink, QAC is present. If deep pink or red, titr. with std Aerosol OT soln; after each addn of std soln, shake mixt. violently 0.5–1 min, let sep., and observe lower layer. Continue addns until no pink is observed in lower layer when placed against white background or compared with blank detn. Titrn found represents amt of QAC in 5 mL sample. Calc. to ppm.

(b) *Water solns*.—Pipet 5 mL sample into g-s test tube contg 2 mL CHCl<sub>2</sub>CHCl<sub>2</sub>, 2 mL buffer soln, and 0.5 mL eosin yellowish soln, and proceed as in (a), beginning "... stopper and shake ca 2 min."

**SALICYLIC ACID****20.093 Preparation of Sample—Official Final Action**

(a) *Nonalcoholic liquids*.—Many liqs may be extd directly as in 20.094 or 20.096 without further treatment. If troublesome emulsions form during extn, pipet 100 mL into 250 mL vol. flask and add ca 5 g NaCl, shaking until dissolved. Dil. to vol. with alcohol, shake vigorously, let stand 10 min, shaking occasionally, filter, and treat aliquot of filtrate as in (b).

(b) *Alcoholic liquids*.—Make 200 mL of sample alk. to litmus paper with ca 10% NaOH soln and evap. on steam bath to ca 1/3 its original vol. Dil. to original vol. with H<sub>2</sub>O and filter if necessary.

(c) *Solid or semisolid substances*.—Grind sample and mix thoroly. Transfer convenient amt (50–200 g according to consistency of sample) to 500 mL vol. flask, add H<sub>2</sub>O to make ca 400 mL, and shake until mixt. becomes uniform. Add 2–5 g CaCl<sub>2</sub> and shake until dissolved. Make distinctly alk. to litmus paper with ca 10% NaOH soln, dil. to vol. with H<sub>2</sub>O, shake thoroly, let stand ≥2 hr, shaking frequently, and filter.

#### Qualitative Tests—Official Final Action

##### 20.094 *Ferric Chloride Test*

(Caution: See 51.011, 51.039, and 51.054.)

Place 50 mL sample or equiv. vol. of aq. ext, prep'd as in 20.093, in separator; add 1/10 its vol. HCl (1+3) and ext with 50 mL ether. If mixt. emulsifies, add 10–15 mL pet ether (bp <60°) and shake. If this treatment fails to break emulsion, centr., or let stand until considerable portion of aq. layer seps; drain latter, shake vigorously, and again let sep. Wash ether layer with two 5 mL portions H<sub>2</sub>O, evap. greater portion of ether in porcelain dish on steam bath, let remainder evap. spontaneously, and add 1 drop 0.5% neut. FeCl<sub>3</sub> soln. Violet color indicates salicylic acid.

If coloring matter or other interfering substance is present in residue after evapn of ether, purify salicylic acid by one of following methods:

(a) Dissolve original residue from ether ext, obtained as above, in ca 25 mL ether; transfer soln to separator and shake with equal vol. H<sub>2</sub>O made distinctly alk. with several drops NH<sub>4</sub>OH (1+9). Let sep., filter aq. layer thru wet paper into porcelain dish, evap. almost to dryness, and test residue with FeCl<sub>3</sub> as above.

(b) Dry original residue from ether ext, obtained as above, in desiccator over H<sub>2</sub>SO<sub>4</sub> and ext with several 10 mL portions CS<sub>2</sub> (Caution: See 51.040 and 51.048) or pet ether (bp <60°), rubbing contents of dish with glass rod and filtering successive portions of solv. thru dry paper into second porcelain dish. Evap. greater portion of solv. on steam bath, let remainder evap. spontaneously, and test residue with FeCl<sub>3</sub> as above.

(c) With few mL of ether, transfer original residue from ether ext obtained as above to small porcelain crucible, and let solv. evap. spontaneously. Cut hole in asbestos board large enough to admit ca 2/3 of crucible, cover crucible with small r-b flask filled with cold H<sub>2</sub>O, and heat over small flame until any salicylic acid present sublimates and condenses upon bottom of flask. Test sublimate with FeCl<sub>3</sub> as above.

##### 20.095 *Jorissen Test (27)*

Dissolve residue from ether ext, 20.094, or, if impurities are present, purified material obtained as in 20.094(a), (b), or (c), in little hot H<sub>2</sub>O. Cool 10 mL soln in test tube and add 4 or 5 drops 10% KNO<sub>2</sub> soln, 4 or 5 drops HOAc (ca 50%), and 1 drop 1% CuSO<sub>4</sub> soln. Mix thoroly, boil liq. 0.5 min, and let stand 2 min. In presence of salicylic acid, Bordeaux-red color develops.

#### Quantitative Method—Official Final Action

##### 20.096

##### Extraction

(Caution: See 51.011, 51.039, and 51.054.)

Transfer to separator 100 mL sample, or vol. soln prep'd as in 20.093 that represents ≥20 g original material. If alk., neutze to litmus with HCl (1+3) and add excess of HCl equiv. to 2 mL acid for each 100 mL soln. Ext 4 times with ether, using for each extn vol. ether equiv. to 1/2 vol. aq. layer. If emulsion forms on shaking, this may usually be broken by adding little (1/5 vol. ether layer) pet ether (bp <60°) and shaking again, or by centrfg. If

small amt of emulsion still persists, let remain with aq. layer, where frequently it is broken during next extn. If emulsion remains after fourth extn, sep. it from clear ether and clear aq. layer and ext sep. with 2 or 3 small portions ether.

Combine ether exts, wash with vol. H<sub>2</sub>O equal to 1/10 total vol. ether exts, let sep., and discard aq. layer. Wash in this way until aq. layer after sepn yields yellow soln upon addn of Me orange soln and 2 drops 0.1N NaOH. Slowly distil greater part of ether, transfer remainder to porcelain dish, and let evap. spontaneously. If no interfering substances are present, proceed as in 20.097; if interfering substances are present, purify residue by one of following methods:

(a) Thoroly dry residue *in vacuo* over H<sub>2</sub>SO<sub>4</sub>. Ext 10 times with 10–15 mL portions CS<sub>2</sub> (Caution: See 51.040 and 51.048) or pet ether (bp <60°), rubbing contents of dish with glass rod, and filter successive portions of solv. thru dry filter into porcelain dish. Test extd residue with drop 2% Fe alum soln, and if it gives reaction for salicylic acid, dissolve in H<sub>2</sub>O; acidify soln with HCl (1+3), ext with ether, evap., ext dry residue thus obtained with CS<sub>2</sub> or pet ether, and add to ext first obtained. Distil greater portion of the CS<sub>2</sub> or pet ether and let remainder evap. spontaneously. Proceed as in 20.097.

(b) Dissolve residue in 40–50 mL ether. Transfer ether soln to separator and ext with three 15 mL portions 1% NH<sub>4</sub>OH. (If fat is known to be present in original ether ext, ext latter directly with 4 portions 1% NH<sub>4</sub>OH instead of 3.) Combine alk. aq. exts, acidify, again ext with ether, and wash combined ether exts as directed previously. Slowly distil greater portion of ether, and let remainder evap. spontaneously.

##### 20.097

##### Determination

Dissolve residue, 20.096, in small amt of hot H<sub>2</sub>O, and after cooling, dil. to definite vol. (usually 50 or 100 mL). If soln is not clear, filter thru dry paper. Dil. aliquots of the soln and treat with 0.5% FeCl<sub>3</sub> soln or 2% Fe alum soln until max. color is developed. Generally few drops will suffice.

(The Fe alum soln should be boiled until ppt appears, allowed to settle, and filtered. Acidity of soln is slightly increased in this manner, but soln remains clear for considerable time, and turbidity caused by its diln with H<sub>2</sub>O is much less and does not appear so soon as when unboiled soln is used. This turbidity interferes with exact matching of color.)

Compare colors developed with color obtained when std salicylic acid soln (contg 1 mg salicylic acid in 50 mL H<sub>2</sub>O) is similarly treated, using Nessler tubes or colorimeter. In either case, and especially with FeCl<sub>3</sub>, avoid excess reagent, although excess of 0.5 mL 2% Fe alum soln may be added to 50 mL comparison soln of salicylic acid without negating results.

#### SORBIC ACID

##### Oxidation Method (28)—Official First Action

(Applicable to cheese)

##### 20.098

##### Apparatus

*Steam distillation apparatus*.—See Fig. 20.03. Trap and distg tube available from SGA Scientific Inc. as Quote FDA No. 584696. Steam generator, Fig. 18.02, may be substituted for 3-neck flask boiler.

##### 20.099

##### Reagents

(a) *Sulfuric acid solns*.—(1) 2N.—Dil. 14.2 mL H<sub>2</sub>SO<sub>4</sub> with H<sub>2</sub>O to 250 mL. (2) 0.3N.—Dil. 15 mL 2N H<sub>2</sub>SO<sub>4</sub> to 100 mL.

(b) *Potassium dichromate soln*.—Dissolve 147 mg K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in H<sub>2</sub>O and dil. to 100 mL with H<sub>2</sub>O.

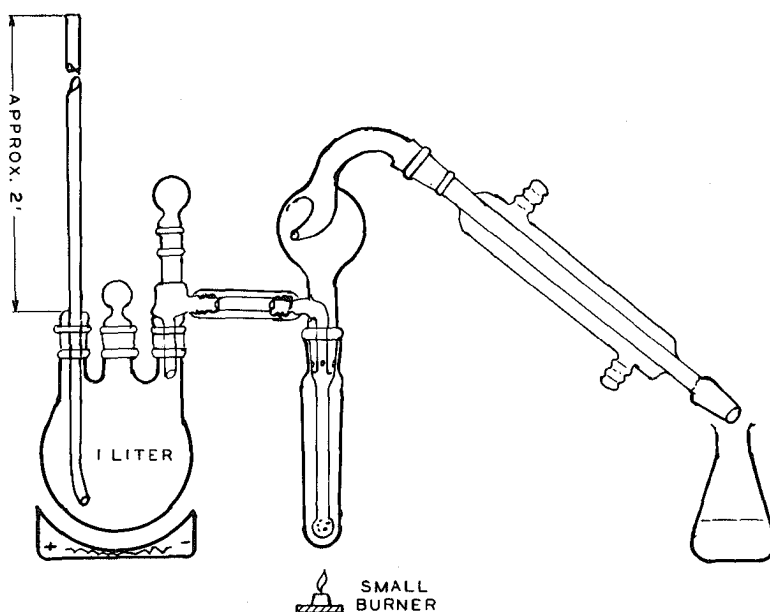

FIG. 20:03—Steam distillation apparatus

(c) *Thiobarbituric acid soln.*—0.5%. Dissolve 250 mg thiobarbituric acid (Eastman Kodak Co. No. 660, or equiv.) in 5 mL 0.5N NaOH in 50 mL vol. flask by swirling under hot H<sub>2</sub>O. Add ca 20 mL H<sub>2</sub>O, neutze with 3 mL 1N HCl, and dil. to vol. with H<sub>2</sub>O. Prep. fresh daily.

(d) *Sorbic acid std soln.*—0.1 mg/mL. Accurately weigh 134 mg K sorbate (equiv. to 100 mg sorbic acid) and dil. to 1 L with H<sub>2</sub>O. Soln is stable several days when refrigerated.

#### 20.100 Preparation of Standard Curve

Just before use, pipet 5, 10, and 15 mL sorbic acid std soln into sep. 500 mL vol. flasks. Dil. each to vol. and mix. Pipet 2 mL each soln and 2 mL H<sub>2</sub>O (for blank) into sep. 15 mL test tubes. Add 1.0 mL 0.3N H<sub>2</sub>SO<sub>4</sub> and 1.0 mL K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> soln, and heat in boiling H<sub>2</sub>O bath exactly 5 min. Immerse tubes in ice bath and add 2 mL thiobarbituric acid soln. Replace in boiling H<sub>2</sub>O bath and heat addnl 10 min. Cool, and det. A of each soln at 532 nm against blank, using matched 1 cm cells. Plot A against  $\mu$ g sorbic acid/mL.

#### 20.101 Determination

Weigh 1.5–2.0 g prepd sample, **16.232**, into distg tube containing SiC chips. Add 10 mL 2N H<sub>2</sub>SO<sub>4</sub> and 10 g MgSO<sub>4</sub>·7H<sub>2</sub>O. Steam distil, maintaining ca 20–30 mL vol. in distg tube with small burner. Avoid charring. Collect 100–125 mL distillate in 250 mL vol. flask within ca 45 min. Rinse condenser with H<sub>2</sub>O, dil. distillate to vol., and mix. If sample contains >0.05% sorbic acid, dil. soln to equiv. concn.

Proceed as in **20.100**, beginning “Pipet 2 mL each soln . . .” Det. concn sorbic acid from std curve and calc. % in sample.

#### Spectrophotometric Method (29)—Official Final Action

(Applicable to fresh dairy products—cottage, ricotta, and mozzarella cheese, sour cream, and yogurt)

#### 20.102 Reagents and Apparatus

(a) *Metaphosphoric acid soln.*—Dissolve 5 g HPO<sub>3</sub> in 250 mL H<sub>2</sub>O and dil. to 1 L with alcohol.

(b) *Mixed ethers.*—Pet ether-anhyd. ether (1+1).

(c) *Potassium permanganate soln.*—Dissolve 15 g KMnO<sub>4</sub> in H<sub>2</sub>O, dil. to 100 mL, and filter thru glass wool.

(d) *Sorbic acid soln.*—(1) *Stock soln.*—1.0 mg/mL. Dissolve 200 mg sorbic acid in 200 mL mixed ethers, (b). (2) *Working soln.*—0.05 mg/mL. Dil. 10 mL stock soln to 200 mL with mixed ethers, (b).

(e) *Reference soln.*—Shake 100 mL mixed ethers, (b), with 10 mL HPO<sub>3</sub> soln, (a), and dry supernate ether soln with 5 g anhyd. granular Na<sub>2</sub>SO<sub>4</sub>.

(f) *Spectrophotometer.*—For use in UV, with matched 1 cm cells, transparent to UV.

#### 20.103 Preparation of Standard Curve

Add 1, 2, 4, and 6 mL working std soln, (d)(2), to sep. 100 mL vol. flasks and dil. to vol. with mixed ethers. Det. A of solns at 250 nm against mixed ethers. Plot A against mg sorbic acid/100 mL.

#### 20.104 Determination

Accurately weigh 10.0 g sample, prepd as in **16.232**, in high-speed blender cup; add enough HPO<sub>3</sub> soln to yield total of 100 mL liq. in mixt. (i.e., to 10.0 g cottage cheese contg 8 g H<sub>2</sub>O, add 92 mL). Blend 1 min and immediately filter thru 18.5 cm Whatman No. 3 paper. Transfer 10 mL filtrate to 250 mL separator contg 100 mL mixed ethers and shake 1 min. Discard aq. layer and dry ether ext with 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub>. Det. A at 250 nm against ref. soln, (e). Det. concn sorbic acid from std curve.

$$\begin{aligned} \% \text{ Sorbic acid} &= (\text{mg sorbic acid/g sample}) \times (1/1000 \text{ mg}) \times 100 \\ &= \text{mg sorbic acid}/10. \end{aligned}$$

Confirm presence of sorbic acid as follows: Add 2 mL KMnO<sub>4</sub> soln to remaining ether soln and shake 1 min. Filter thru Whatman No. 3 paper, add 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub>, shake, and scan spectrum between 300 and 220 nm. Absence of peak at 250 nm confirms presence of sorbic acid in sample.

## SULFUROUS ACID

### 20.105 Qualitative Test (30)—Official Final Action

Add small amt of S-free Zn and several mL HCl to ca 25 g sample (with addn of H<sub>2</sub>O, if necessary) in 200 mL erlenmeyer. H<sub>2</sub>S generated in presence of sulfites may be detected with Pb(OAc)<sub>2</sub> paper. Traces of metallic sulfides occasionally present in vegetables give same reaction as sulfites under conditions of above test. Verify positive results obtained by this method by Monier-Williams method, 20.108.

It is always advisable to make quant. detn of sulfites because of possibility of pos. test caused by traces of sulfides. Trace should not be considered sufficient indication of presence of SO<sub>2</sub> either as bleaching agent or as preservative.

## Total Sulfurous Acid

### Modified Monier-Williams Method (31) Official Final Action

(Applicable in presence of other volatile S compds; not applicable to dried onions, leeks, and cabbage.)

### 20.106

### Reagents

(a) *Hydrogen peroxide soln.*—3%. Check 30% ACS reagent to ensure compliance with sulfate specification. Det. H<sub>2</sub>O<sub>2</sub> content by KMnO<sub>4</sub> titrn, dil. to ca 6% H<sub>2</sub>O<sub>2</sub>, neutze to Me red, (b), and dil. to calcd vol. to give 3.0%.

(b) *Methyl red indicator.*—0.25% in alcohol. Adjust to transition color.

### 20.107

### Apparatus

See Fig. 20.04. Connect 3 neck (24/40) 1 L distg flask at an outer neck to 30 cm Allihn condenser (Ful-Jak, SGA Scientific Inc. No. JC-5450, or equiv.) in reflux position. (Condenser must condense all HCl but none of SO<sub>2</sub>.) Place inner joint adapter with right angle hose connection in condenser and connect thru piece of 1/4 × 6" silicone tubing (SGA Scientific Inc. No. R-8425) preboiled in HCl (1+20) and rinsed with H<sub>2</sub>O, to set of 2 U-tubes of 20 mm tubing, ball joint 35/20, 55±5 mm center to center and 150±5 mm long, connected with cross-over tube, ball joint 35/20, 55±5 mm center to center and 115±5 mm long. To each U-tube add 2 ca 25 mm lengths of solid glass tube, 10 mL 3 mm glass beads at exit side, and 10 mL 3% H<sub>2</sub>O<sub>2</sub> contg drop Me red.

Attach either curved gas inlet tube for outer neck or straight tube for center neck of distg flask with tip reaching nearly to bottom.

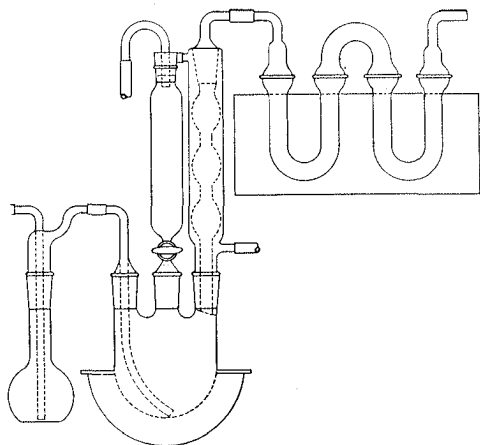

FIG. 20.04—Apparatus for modified Monier-Williams method for sulfur dioxide

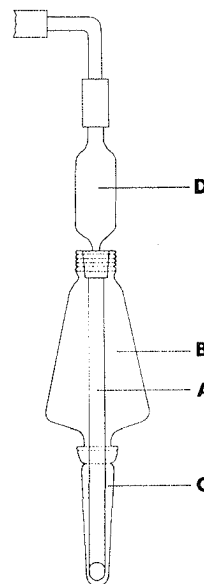

FIG. 20.05—Alternative SO<sub>2</sub> absorber

Alternatively substitute app. shown in Fig. 20.05 for U-tubes. Connect right angle hose connection to 30–50 mL bulb (D) and fritted cylindrical gas dispersion tube (A) (SGA Scientific Inc. No. G-5420, or equiv.). Suspend fritted end near bottom of Kuderna-Danish Evaporative Concentrator (B, C) (Kontes Glass Co. No. K-570000, part B, vol. 500 mL, 24/25 lower joint; part C, ca 15 mL, 24/25 joint) contg 10–12 mL 3% H<sub>2</sub>O<sub>2</sub> and drop Me red. Diam. of C should provide min. gas scrubber path of 10 cm with 10 mL H<sub>2</sub>O<sub>2</sub>.

Grind 4.5 g pyrogallol with 5 mL H<sub>2</sub>O in small mortar and transfer slurry to 250 mL 24/40 gas washing bottle. Repeat grinding and transfer with two 5 mL portions H<sub>2</sub>O. Pass H<sub>2</sub>O-pumped N from tank thru 2-stage regulator into gas washing bottle to flush out air and add to bottle, thru long stem funnel, cooled soln of 65 g KOH in ca 85 mL H<sub>2</sub>O. (Prep. complete soln fresh daily.) Turn off N, and attach 1/4 × 6" silicone tubing, preboiled in HCl (1+20) and rinsed with H<sub>2</sub>O, to exit end and to gas inlet tube of distg flask. Clamp off both ends of washing bottle.

Attach 125 mL separator thru 24/40 joint to third neck of distg flask. Attach piece of rubber tubing to short U-tube inserted thru rubber stopper in neck of separator. Blow into rubber tubing, and close separator stopcock. Let stand for few min to check for leaks shown by liqs leveling in U-tubes.

Place distg flask in heating mantle controlled by variable transformer.

### 20.108

### Determination

Place sample, contg ≥45 mg SO<sub>2</sub>, in distg flask, using H<sub>2</sub>O for transferring, if necessary. Dil. to ca 400 mL with H<sub>2</sub>O. Add 90 mL HCl (1+2) to separator and force HCl into flask with gentle pressure. Start N flow at slow steady stream of bubbles. Heat flask to cause refluxing in 20–25 min (ca 80 volts on 7 amp transformer). When steady refluxing is reached, apply line voltage and reflux 1.75 hr. Turn off H<sub>2</sub>O in condenser and continue heating until inlet joint of first U-tube shows condensation and slight warming. Remove separator, and turn off heat. When joint at top of condenser cools, remove connecting assembly and rinse into second U-tube. Attach cross-over tube to exit joint of first U-tube, rotate until open ends touch, add drop Me red, and titr. with 0.1N NaOH just to clear yellow,

mixing with gentle rocking. 1 mL 0.1*N* NaOH = 3.203 mg SO<sub>2</sub>. Titr. second U-tube similarly. If alternative app. is used, disconnect, and rinse bulb *D* and tube *A* with few mL H<sub>2</sub>O into Kuderna-Danish app. *B*, *C*. Add 2 drops Me red and titr. with 0.1*N* NaOH.

Gravimetric detn may be made after titrn by rinsing tubes into 400 mL beaker. Add 4 drops 1*N* HCl and excess of filtered 10% BaCl<sub>2</sub> soln, and let stand overnight. Wash ppt by decantation 3 times with hot H<sub>2</sub>O thru weighed gooch. Wash with 20 mL alcohol and 20 mL ether, and dry at 105–110°.

mg BaSO<sub>4</sub> × 274.46/g sample = ppm SO<sub>2</sub>.

Det. blank on reagents, both by titrn and gravimetrically, and correct results accordingly.

### Colorimetric Method (32)—Official Final Action

(Applicable to dried fruit)

#### 20.109

#### Reagents

(a) *Formaldehyde soln.*—0.015%. Prep. from 40% HCHO by dilg in 2 steps: 10 to 1000, and 75 to 2000.

(b) *Acid-bleached *p*-rosaniline hydrochloride.*—Place 100 mg *p*-rosaniline.HCl (Allied Chemical Corp.) and 200 mL H<sub>2</sub>O in 1 L vol. flask. Add 160 mL HCl (1+1) and dil. to vol. Let stand 12 hr before use.

(c) *Sodium tetrachloromercurate.*—Place 23.4 g NaCl and 54.3 g HgCl<sub>2</sub> in 2 L vol. flask. Dissolve in ca 1900 mL H<sub>2</sub>O and dil. to vol. (Caution: See 51.079.)

(d) *Sulfur dioxide std soln.*—Dissolve ca 170 mg NaHSO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L. Stdze with 0.01*N* I soln before use (ca 100 µg SO<sub>2</sub>/mL).

#### 20.110

#### Preparation of Standard Curve

Add 5 mL mercurate reagent to series of 100 mL vol. flasks; then add 0, 1.0, 2.0, 3.0, etc., mL of SO<sub>2</sub> std soln. Dil. to vol. and mix. Transfer 5.0 mL portions to 200 mm test tubes contg 5 mL rosaniline reagent. Add 10 mL 0.015% HCHO soln, mix, and hold 30 min at 22°. Read *A* at 550 nm against 0 std and plot std curve.

#### 20.111

#### Determination

Weigh 10±0.02 g ground dried fruit and transfer to blender with 290 mL H<sub>2</sub>O. Cover and blend 2 min. Withdraw 10 g aliquot from bottom of blender with 10 mL calibrated free-running pipet, and transfer to 100 mL vol. flask contg 4 mL 0.5*N* NaOH. (Use 2 mL for apples and 1 mL for golden raisins.) Swirl and mix ca 13–30 sec. Add 4 mL 0.5*N* H<sub>2</sub>SO<sub>4</sub> (2 mL for apples and 1 mL for golden raisins) and 20 mL mercurate reagent, and dil. to vol. For blank, omit 10 mL fruit ext.

Transfer 2 mL sample soln to 200 mm test tube contg 5 mL rosaniline reagent. Add 10 mL 0.015% HCHO soln, mix, and hold 30 min at 22°. Read *A* at 550 nm against blank. Refer to std curve and convert results to ppm SO<sub>2</sub>.

(If same colorimeter tube or cell is used for successive samples, clean between use with HCl (1+1) and H<sub>2</sub>O.)

### Sulfites in Meats (33)—Official Final Action

#### Qualitative Test

#### 20.112

#### Reagent

*Malachite green soln.*—Dissolve 200 mg malachite green, certified by Biological Stain Commission, in H<sub>2</sub>O and dil. to 1 L. Soln is stable for several weeks if dispensed from polyethylene dropper bottle assembly with Neoprene bulb. Discard when visible deterioration occurs. (Tablets for prepn of 15 mL reagent are available from LaMotte Chemical Products Co., Chestertown, MD 21620.)

#### 20.113

#### Test

Transfer ca 3.5 g (½ teaspoonful) ground meat to 10 × 10 cm sq of waxed white freezer paper or other impervious white surface. Add 0.5 mL reagent and mix vigorously 2 min with hardwood tongue blade or spatula, turning mass frequently. Observe color after few min.

Dye is decolorized in presence of sulfites. Normal meat becomes blue-green. Verify pos. results by Monier-Williams method, 20.108.

#### 20.114 Free Sulfurous Acid (34)—Official Final Action

Treat 50 mL sample in 200 mL flask with ca 5 mL H<sub>2</sub>SO<sub>4</sub> (1+3), add ca 0.5 g Na<sub>2</sub>CO<sub>3</sub> to expel air, and titr. H<sub>2</sub>SO<sub>3</sub> with 0.02*N* I, using few mL starch indicator, 6.005(f). Add I soln as rapidly as possible and continue addn until soln stays blue several min. 1 mL 0.02*N* I = 0.64 mg SO<sub>2</sub>.

### THIOUREA (35)

#### Qualitative Tests—Procedure

(Applicable to orange juice)

#### 20.115 Pentacyanoammonioferroate Test

(a) *Reagent.*—(Caution: See 51.050.) Dissolve 10 g Na<sub>2</sub>Fe(CN)<sub>5</sub>NO·2H<sub>2</sub>O in 40 mL NH<sub>4</sub>OH and let stand at ca 0° until all nitrosoferricyanide decomposes (shown when few drops mixt. no longer give red soln when added to soln of creatinine in 1*N* NaOH; decomposition is complete after 24 hr). Filter, and add absolute alcohol to filtrate until there is no further pptn of pentacyanoammonioferroate. Filter, wash with absolute alcohol until NH<sub>3</sub>-free, dry *in vacuo* over H<sub>2</sub>SO<sub>4</sub>, and store in desiccator over CaCl<sub>2</sub> in dark. Reagent is 1% soln of this salt in H<sub>2</sub>O, exposed to light and air 1 day and then stored in brown glass bottle in dark. It gains in potency for several weeks, and can be kept ca 6 months.

(b) *Test.*—Ext orange juice with ca ⅓ vol. ether, centrf., and sep. lower layer. Stir in some Filter-Cel and filter with suction. Keep vac. on short time and agitate soln to remove most of ether. To ca 5 mL filtered soln add 5 drops reagent and note color. If blue color does not develop, add I soln, ca 0.1*N*, dropwise, shaking after each drop. Blue-green soln indicates presence of CS(NH<sub>2</sub>)<sub>2</sub>. (Usually ca 5 drops I soln are necessary to develop max. color; excess I tends to reduce color.)

#### 20.116 Grote Reagent Test

To 5–10 mL orange juice, ether-extd and filtered as in 20.115(b), add 0.02*N* I dropwise until I color does not immediately disappear. Add few mL dil. Grote reagent, 20.118(b). Blue-green or blue color developing rather gradually indicates presence of CS(NH<sub>2</sub>)<sub>2</sub>.

### Quantitative Methods

#### Rapid Oxidation Method for Orange Juice Official Final Action

#### 20.117

#### Apparatus

*Siphon.*—Insert 2 bent glass tubes in 2-hole cork or stopper, one terminating just below stopper (blow tube) and other (siphon tube) long enough to reach bottom of centrf. bottle when cork with tubes is inserted in mouth of bottle. Attach another glass tube to outside end of siphon tube with flexible rubber tube so that end of outside tube is below end of inside tube. This assembly is used to siphon lower layer from centrf. bottle, and rate of flow is controlled by squeezing rubber

connection. Prep. cap for inner siphon tube by boring hole of same diam. as tube part way thru small cork.

## 20.118

## Reagents

(a) *Modified Grote reagent*.—Dissolve 0.5 g  $\text{Na}_2\text{Fe}(\text{CN})_6\text{NO} \cdot 2\text{H}_2\text{O}$  in 10 mL  $\text{H}_2\text{O}$  in 50 mL erlenmeyer. Weigh 0.5 g  $\text{NH}_2\text{OH} \cdot \text{HCl}$  and 1 g  $\text{NaHCO}_3$ . Uniformly mix the 2 solids in small beaker or porcelain dish by gentle grinding with small pestle or flat-end glass rod, crushing any lumps in sample. Brush off rod or pestle and quant. transfer mixed solid to nitroprusside soln with aid of short-stem funnel and brush. Do not agitate flask but let it stand until  $\text{CO}_2$  evolution nearly stops. Then swirl to dissolve any remaining  $\text{NaHCO}_3$ . When evolution of  $\text{CO}_2$  practically ceases, add 0.10 mL Br (11 small drops). Second evolution of gas occurs. When agitation no longer produces effervescence, dil. to 25 mL with  $\text{H}_2\text{O}$  and filter. Test reagent as follows: Dil. 2 mL as in (b); add 1 mL dild reagent to 10 mL soln composed of 5 mL thiourea stock soln, (c), (dild  $10\times$ ), 5 mL  $\text{H}_2\text{O}$ , and 1 drop HOAc. Strong blue color should develop in 5 min. If it does not, prep. new reagent and repeat test. Store at room temp. 5–10 hr to age soln. (Soln should be mahogany brown. If it has greenish cast, it is not as effective and soon loses its value.) This stock soln keeps several weeks when stored in refrigerator.

(b) *Dilute Grote reagent*.—Dil. 1 vol. reagent (a) with 4 vols  $\text{H}_2\text{O}$ . Use 1 mL dild reagent for each detn. Dild reagent keeps 1 day.

(c) *Thiourea stock soln*.—Dissolve 100 mg  $\text{CS}(\text{NH}_2)_2$  in  $\text{H}_2\text{O}$  and dil. to 200 mL.

(d) *Citrate soln*.—Dissolve 0.84 g  $\text{K}_3\text{C}_6\text{H}_5\text{O}_7 \cdot \text{H}_2\text{O}$  and 1 g citric acid in  $\text{H}_2\text{O}$ , and dil. to 100 mL.

(e) *Sulfuric acid*.— $1.00 \pm 0.02N$ .

## 20.119

## Preparation of Sample

Juice oranges in ordinary reamer, strain out seeds and pulp, and mix well. Measure 125 mL into 250 mL centr. bottle, add 70 mL ether, and shake well 1–2 min. Centrf. ca 10 min at 1800 rpm. Cap short end of siphon tube (inside bottle), insert into bottle, and lower thru top layer into lower aq. layer. Push off cork cap with glass rod. Lower tube to bottom of bottle, push cork (which carries both tubes) into mouth of bottle, and blow in short tube to start flow of liq. Carefully siphon into beaker as much of lower layer as possible, controlling rate of flow by squeezing on rubber connection. Stop flow when material from center emulsion layer begins to enter tube.

Add teaspoonful of Filter-Cel to siphoned liq. in beaker, stir well, and filter on buchner (7–11 cm) with suction, using Whatman 54 or 41-H paper. Measure filtrate with graduate, pour into separator, and add ca  $\frac{1}{2}$  its vol. ether. Shake well, let sep., drain lower layer into beaker, add pinch of Filter-Cel, stir well, and filter thru Whatman No. 12 folded filter. Place filtrate in clean, dry suction flask, warm on steam bath to  $36^\circ$ , and apply suction to remove ether.

Pipet 25 mL filtrate (clear or nearly so) into clean 50 mL vol. flask. In 2 similar flasks place 25 mL aliquots citrate soln. To one flask add 2 mL thiourea stock soln; use other as a blank. To each of the 3 flasks add 5 mL  $1N \text{H}_2\text{SO}_4$ . Slowly add  $0.1N \text{I}$ , 50.018, with rotation, to each flask until I color does not disappear; then add 1 mL excess. Let flasks (samples, std, and blank) stand 10 min at room temp. Now add soln of  $\text{NaHSO}_3$  (2.5 g/L) to contents of flasks until I color disappears; add 3 or 4 drops excess. Add 4 mL 25%  $\text{NaOAc}$  soln gradually and slowly to each flask, with swirling, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Filter if cloudy. Designate oxidized dild sample as Soln X.

## 20.120

## Determination

Prep. 2 stds by placing 5 and 10 mL portions of soln from the std flask in test tubes. Dil. first tube to 10 mL by adding 5 mL liq. from blank soln (no thiourea). Place 10 mL portions blank soln and sample Soln X in 2 other test tubes. Pipet 1 mL dild Grote reagent (*Caution: See 51.018 and 51.050*) into each tube with shaking or stirring. Let tubes stand 1 hr at ca  $25^\circ$ , or 10–15 min in bath at  $45\text{--}50^\circ$ , to develop blue color. Read developed color of solns from each tube (sample, blank, and stds) in spectrophtr at 610 nm. From readings of blank and stds construct curve (linear), plotting  $A$  against ppm  $\text{CS}(\text{NH}_2)_2$ . Oxidized std in flask represents 20 ppm (1 mg/50 mL); 10 mL aliquot therefore represents 20 ppm, and 5 mL, 10 ppm.

Slight correction on sample color reading obtained is necessary because of natural color present in Soln X before addn of Grote reagent. Obtain readings on blank soln and sample Soln X contained in vol. flask, without added reagent, using same photometer cell. Subtract difference between these readings ( $X - \text{blank}$ ) from sample reading with Grote reagent. Obtain from graph ppm  $\text{CS}(\text{NH}_2)_2$  corresponding to corrected reading. This value  $\times 2 = \text{CS}(\text{NH}_2)_2$  concn in original orange juice.

## Method for Frozen Peaches—Official First Action

## 20.121

## Preparation of Sample

(*Caution: See 51.011, 51.039, and 51.046.*)

Weigh 200–400 g frozen sample on rough balance (0.1–0.2 g sensitivity) into tared 800 mL beaker. Cut contents of 1 lb (450 g) package into quarter or eighth portions, select alternate portions for detn, and keep remainder as reserve sample. (Several packages can be composited in this manner if desired.)

Immediately add to sample, vol.  $\text{NaHSO}_3$  soln (2.5 g/L) equal to  $\frac{1}{2}$  wt sample (*See Note*). Mix and pour into high-speed blender (or other mixing machine), drain well, and blend 20–30 sec. Return dild comminuted sample to beaker.

Weigh  $150 \pm 0.2$  g blended sample, transfer to 250 mL vol. flask, and dil. to ca 200 mL with  $\text{H}_2\text{O}$ . Add ca 4 drops *hexyl alcohol* and attach to flask 2-hole stopper (No. 0), carrying small bent glass tube and another straight tube, extending ca 8 cm into flask, end of which is drawn to small bore (near capillary). Remove most of air by applying gentle suction to bent tube and shaking flask with rotation. (Bore of small tube should be large enough so that reduction of pressure is not too great.) If froth rises in neck, release vac. for moment. Continue with suction and rotation until most of air is removed, add 20 mL addnl  $\text{NaHSO}_3$  soln, and dil. to vol. with  $\text{H}_2\text{O}$ . Mix well and pour ca 165 mL into 250 mL centr. bottle. Add 50 mL ether to bottle, rotate few times, stopper, and shake; open once to release pressure; then shake vigorously 1–1.5 min. (If preferred, divide liq. in vol. flask between 2 centr. bottles and ext each with ca 30 mL ether, etc.)

Centrf. ca 10 min at ca 1800 rpm. Carefully pour off little of top ether layer into beaker; then inclining bottle, push sludge cake toward bottom of bottle with glass rod and pour liq. contents on cotton filter in funnel. To prep. filter, place small cotton pledget in apex of 85–100 mm funnel, and insert piece of absorbent cotton of half thickness (split sheet), ca 9 cm diam.

Pipet 100 mL lower aq. filtrate into 200 mL vol. flask, squeezing cotton on side of funnel with rod if necessary to obtain enough filtrate. Gradually add enough acetone to contents of flask (from separator), with const shaking, to bring contents to 200 mL mark. As surface of liq. enters neck of flask, stopper, and mix by inverting few times before dilg to mark. Mix, cool to room temp. (in bath if desired), dil. to mark again, and mix well.

(Acetone causes some rise in temp.) Let ppt sep. and pour contents of flask into 250 mL centr. bottle. Add 1 spoonful of Filter-Cel, stopper, and shake well. Centr. ca 8 min at ca 1800 rpm. Decant supernate and filter if turbid. Measure 125 mL clear liq. into 250 mL beaker, add several glass beads, and boil off acetone on steam bath. Then boil down to ca 35 mL on hot plate, remove, and cool to room temp. Add 15% NaOH soln dropwise until alk. and ca 2 drops excess. Add HOAc (1+5) with stirring until just acid and add 2 drops excess.

Quant. transfer liq. to 50 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix. Pour contents of flask into small beaker or flask (100–125 mL), add 1 spoonful Filter-Cel, and mix well by stirring or stoppering and shaking. Filter liq. on 12.5 cm folded paper (Eaton-Dikeman 195 is suitable). Pour thru filter again if not clear. Filtrate or final sample soln is designated FS.

## 20.122

### Determination

Pipet 10 mL Soln FS into 150 mm test tube. For  $\leq 50$  ppm CS(NH<sub>2</sub>)<sub>2</sub>, prep stds contg 0, 1, 2, and 4 mL portions of 1 + 9 diln CS(NH<sub>2</sub>)<sub>2</sub> stock soln, **20.118(c)** (5 mg CS(NH<sub>2</sub>)<sub>2</sub>/100 mL). Add 0.6% Na citrate soln to tubes to make stds to 10 mL; then add 1 drop HOAc (1+5) to each tube (samples and stds). Place stirring rod in each tube and stir up and down to mix, leaving rod in tube. Place tubes in bath or room held at 20–25°.

Add to each tube, with stirring, 1 mL dil. Grote reagent, (b) (recently dild). Let tubes stand 60 min at 20–25° and det. A of each soln in spectrophtr at ca 610 nm. Designate reading of sample as X. Construct linear curve from std readings, plotting ppm CS(NH<sub>2</sub>)<sub>2</sub> (1 mL std soln = 10 ppm CS(NH<sub>2</sub>)<sub>2</sub> in sample) against A. Extrapolate std curve up to 50 ppm.

To correct reading X for natural color present in soln before reagent is added, make readings of Soln FS with no added reagent in same cell and also that of H<sub>2</sub>O. FS reading – H<sub>2</sub>O reading = d;  $X - d = R$  (corrected reading). From reading R obtain ppm CS(NH<sub>2</sub>)<sub>2</sub> in Soln FS, using curve. Multiply CS(NH<sub>2</sub>)<sub>2</sub> thus found by factor 1.065 to correct for vol. increase due to solubility of ether and obtain true CS(NH<sub>2</sub>)<sub>2</sub> content of original sample. Repeat detn (color development) on smaller aliquot (1–5 mL) for amts >50 ppm.

*Note:* Sample of 200 g is enough to be representative and should be used where portion is to be reserved. Keep unused portion of sample frozen. It is necessary to add the NaHSO<sub>3</sub> soln to frozen sample immediately before blending to prevent losses of CS(NH<sub>2</sub>)<sub>2</sub> due to attack by enzyme systems present. Blender whips air thruout the material, and if enzymes are not inactivated, large losses of CS(NH<sub>2</sub>)<sub>2</sub> may occur. Enzymes can also be inactivated by plunging frozen sample into boiling H<sub>2</sub>O and boiling 3 or 4 min. Action of enzymes is slow in frozen condition if material is unbroken cakes or chunks.

### Method for Orange Peel—Official Final Action

## 20.123

### Reagents

- Thiourea std soln.—0.5 mg/mL. See **20.118(c)**.
- Diluted modified Grote reagent.—Dil. modified Grote reagent, **20.118(a)**, with 2 vols H<sub>2</sub>O just before use.
- Extraction solvent.—Mix EtOAc with acetone (2+1).
- Dilute phosphoric acid.—0.9±0.1N, stdzd to phthin end point.

## 20.124

### Preparation of Sample

(Caution: See **51.004**, **51.039**, and **51.054**.)

Bisect 6–8 fruit and ream firmly to remove all possible juice

without removing peel. Pass peel thru food chopper or grinder and mix thoroly in bottle.

Weigh 75 g sample into high-speed blender cup. Add 250 mL ether and blend 2 min in hood with draft operating. Filter on 11 cm buchner with moderate suction and rinse blender and filter with ether, pressing down cake with bottom of 100–150 mL beaker. Remove ether from suction flask, discard ether, and continue suction on cake to remove ether.

Remove buchner from flask and transfer cake to 750 mL (135 mm diam.) casserole. Strip off paper, and transfer any remaining peel on paper or in funnel to casserole with spatula. Add 100 g anhyd. Na<sub>2</sub>SO<sub>4</sub> and mix well with spatula and spoon. Transfer mixt. to blender, dry-wash casserole with little more Na<sub>2</sub>SO<sub>4</sub>, and add to blender. Add ca 275 mL extn solv., blend at low speed, and gradually increase to full speed, using variable transformer. Blend at full speed 3 min, and filter into 11 cm buchner, using Whatman 41-H paper with moderate suction, transferring most of residue with policeman and few small spurts of extn solv. from wash bottle. Distribute residue over filter, press down cake with bottom of 100–150 mL beaker, and suck dry. Remove cake and return to blender, stripping off paper. Add 150 mL extn solv., and blend ca 2 min. Filter on buchner, rinse blender and filter with ca 50 mL extn solv., and suck dry. Combine extn solv. filtrates, add 1.2 mL 0.9N H<sub>3</sub>PO<sub>4</sub>, dil. to convenient vol. in flask or graduate, and mix.

Accurately measure 2 aliquots of solv. ext, each equiv. to 10 g sample, into 150 mL beakers, and evap. on steam bath sep. to ca 12 mL. Cool, add small amt of Celite, and stir. Filter each soln into sep. side arm test tube thru fritted filter tube or crucible overlaid with fine, firm asbestos mat or thru small buchner and S&S 589 Blue Ribbon paper, using moderate suction. Rinse beaker and filter with 3 mL EtOAc.

Quant. transfer filtrates to small separators with aid of eye-dropper pipet and bulb, rinsing with ca 1 mL EtOAc. Ext with two 5 mL portions H<sub>2</sub>O, shaking well and letting sep. each time. Combine aq. exts of each detn in small beaker and boil ca 20 sec to remove most of org. solv. Cool, dil. each to 10 mL with H<sub>2</sub>O in vol. flask, and mix well.

## 20.125

### Determination

Pipet 5 mL aliquots of final aq. solns from each detn into 25 mm diam. test tubes. Add 0.5 mL dild modified Grote reagent, **20.123(b)**, mix, and det. A after 75 min against blank as in **20.126**. Det. mg thiourea from std curve.

To correct for loss of thiourea, if any, during evapn of org. solv., place same vol. extn solv. as contained equiv. of 10 g sample in 150 mL beaker, add 0.6 mL thiourea std soln (0.3 mg) and 0.12 mL 0.9N H<sub>3</sub>PO<sub>4</sub>, and evap. to ca 12 mL on steam bath. Proceed as in **20.124**, par. 4, beginning "Cool, add small amt of Celite, and stir."

Correct thiourea found in sample aliquot, if necessary, for loss on evapn. Calc. to original sample basis.

## 20.126

### Preparation of Standard Curve

Prep. blank soln contg 1.20 mL 0.9N H<sub>3</sub>PO<sub>4</sub> dild to 100 mL with H<sub>2</sub>O. Pipet 6 mL thiourea std soln into 100 mL vol. flask, add 1.20 mL 0.9N H<sub>3</sub>PO<sub>4</sub>, and dil. to vol. with H<sub>2</sub>O. Place 1.0, 2.5, and 5.0 mL aliquots of this std soln in 25 mm diam. test tubes and add 4.0, 2.5, and 0 mL blank soln. Place 5.0 mL blank soln in similar tube. To all solns add 0.5 mL dild modified Grote reagent, mix, and let stand 1 hr. Read A of stds against blank at 610 nm. Plot mg thiourea against A. Check std curve occasionally and prep. new curve with each new lot of modified Grote reagent.

## EMULSIFYING AGENTS

### Polysorbate 60 (Polyoxyethylene (20) Sorbitan Monostearate) (36)—Official First Action

(Applicable to shortening, food oils, and nonstdzd dressings)

#### 20.127

#### Principle

Polysorbate 60 is extd from dressing with  $\text{CHCl}_3$ -absolute alcohol (93+7). Shortening or dressing ext is saponified with alc. KOH and acidified; fatty acids are extd with hexane. Aq. polyol soln is desalted by mixed-bed ion exchange and Ba phosphomolybdate is used to ppt polyoxyethylated polyols as insol. heteropoly acid complex. Ppt is dried to const wt and polysorbate 60 content is calcd using gravimetric factor obtained by analyzing known amts polysorbate 60. Method is applicable in range 0.1–1.0% polysorbate 60.

#### 20.128

#### Apparatus

(a) *Reflux apparatus*.—(1) Alkali-resistant erlenmeyers,  $\text{F}$  24/40 g-s joint, 300 mL; with (2) enlarging adapter tubes, g-s joint,  $\text{F}$  29/42 top outer,  $\text{F}$  24/40 bottom inner; (3)  $\text{H}_2\text{O}$ -cooled condensers,  $\text{F}$  29/42 g-s joint.

(b) *Ion exchange tube*.—400  $\times$  28 mm id,  $\text{F}$  29/42 top outer g-s and Teflon stopcock, coarse fritted glass disk; 250 mL addn funnel,  $\text{F}$  29/42 g-s joint fitted with glass drip tip.

(c) *Extraction apparatus*.—Soxhlet extn tube, 40 mm id; Whatman extn thimbles, 8  $\times$  33 mm; and 250 mL extn flasks with caps.

#### 20.129

#### Reagents

(a) *Alcoholic potassium hydroxide soln*.—1*N* in absolute alcohol.

(b) *Mixed-bed ion exchange resin*.—Illco exchange resin, research grade TMD-8 (anion-dyed) (Illinois Water Treatment Co., 4669 Shepherd Trail, Rockford, IL 61105).

(c) *Asbestos*.—Medium fiber, gooch grade. (*Caution*: See 51.086.)

(d) *Absorbing filter aid*.—Hyflo Super-Cel, or equiv.

#### 20.130

#### Determination

(a) *For shortening and food oils*.—Weigh sample contg 10–40 mg polysorbate 60 (total wt  $\leq$  9 g) into 300 mL alkali-resistant flask. Add 50 mL 1*N* alc. KOH, and attach adapter tube and reflux condenser. Reflux 45 min on hot plate. Add 10 mL  $\text{H}_2\text{O}$  and continue refluxing addnl 45 min. Transfer quant. to 250 mL separator with ca 50 mL ca 60°  $\text{H}_2\text{O}$ . Add 4.5 mL HCl and mix by swirling. Cool so that separator may be held comfortably in hand. Add 50 mL redistd hexane, shake vigorously, and let sep. Drain lower layer into second separator and ext with another 50 mL portion hexane. Drain lower layer into 250 mL addn funnel. Combine hexane exts and wash with two 20 mL portions alcohol (1+1). Combine aq. alc. exts in addn funnel and cool to room temp.

Pour aq. suspension of mixed-bed resins, 20.129(b), into tube, to bed ht ca 30 cm. Add polyol soln to column from addn funnel, and adjust flow to ca 2 mL/min. Collect eluate in 600 mL beaker. Rinse sides of tube and wash resin bed with 200 mL  $\text{H}_2\text{O}$ . (Rate may be increased to 3–4 mL/min during washing step.) Evap. combined eluates in steam bath to 300 mL (support lip of beaker on edge of bath opening.) Remove hot soln and immediately add 2.0 mL 3*N* HCl, 4.0 mL 10%  $\text{BaCl}_2$  soln, and 4.0 mL 10% phosphomolybdic acid soln to ppt Ba phosphomolybdic-polyol complex. Stir soln and let stand overnight.

Filter thru 40 mL size gooch provided with asbestos mat, previously dried at 110° and weighed. Quant. transfer ppt with

rubber policeman and  $\text{H}_2\text{O}$  wash. Wash ppt in gooch with 50 mL  $\text{H}_2\text{O}$ . Dry 1 hr in 110° oven. Cool in desiccator, and weigh.

Det. gravimetric factor by analyzing known amt (ca 25 mg) polysorbate 60.

$$\% \text{ Polysorbate 60} = (C \times 100)/(F \times W),$$

where  $C$  = g dry ppt,  $W$  = g sample,  $F$  = gravimetric factor = wt complex/unit wt polysorbate 60 (ca 2.8).

(b) *For nonstandardized dressings*.—Weigh sample contg 10–40 mg polysorbate 60 (total wt  $\leq$  9 g) into 150 mL beaker and mix thoroly with 7 g Hyflo Super-Cel. Transfer mixt. to Soxhlet thimble, and ext 16 hr in Soxhlet app. with 150–200 mL  $\text{CHCl}_3$ -absolute alcohol (93+7). Quant. transfer ext to 300 mL alkali-resistant flask, and evap. solv. on steam bath using boiling rod. (*Caution*: See 51.056.) To ensure complete removal of  $\text{CHCl}_3$  from residue, add 50 mL absolute alcohol and evap. to dryness again. Proceed as in (a), par. 1, line 3, beginning "Add 50 mL 1*N* alc. KOH, . . ."

### Sodium Lauryl Sulfate (37)—Official Final Action

#### 20.131

#### Reagents

(*Caution*: See 51.022, 51.028(a) and (d), and 51.079.)

(a) *Crystal violet indicator*.—See 3.156(d).

(b) *Methyl yellow indicator*.—Dissolve 40 mg *p*-dimethylaminoazobenzene in 100 mL MeOH. (*Caution*: See 51.085.)

(c) *Standard acetous perchloric acid*.—0.1*N*. Mix 8.5 mL 72%  $\text{HClO}_4$  with 500 mL HOAc and add 30 mL  $\text{Ac}_2\text{O}$ . Cool, and dil. to 1 L with HOAc. Let stand 24 hr before using. Stdze as follows: Accurately weigh 400–500 mg KH phthalate, previously dried 2 hr at 105°, into 250 mL erlenmeyer and dissolve in 80 mL HOAc. Add 3 drops crystal violet indicator and titr. with acetous  $\text{HClO}_4$  to blue-green end point, which is stable 60 sec. Perform blank titrn on 80 mL HOAc and 3 drops indicator soln, and correct vol. of titrant.

$$N = \text{mg KHC}_8\text{H}_4\text{O}_4 / (204.23 \times \text{mL HClO}_4)$$

(d) *Mercuric acetate soln*.—6%. Dissolve 6.0 g  $\text{Hg}(\text{OAc})_2$  crystals in 100 mL HOAc, heating gently, if necessary, to dissolve.

(e) *Azure A soln*.—Dissolve 40 mg dye (CI No. 52005) in  $\text{H}_2\text{O}$ , add 10 mL 0.1*N*  $\text{H}_2\text{SO}_4$ , and dil. to 100 mL.

(f) *Benzethonium chloride*.—Approx. 99% pure (available from Aldrich Chemical Co., Inc.). Det. purity as follows: Accurately weigh ca 1 g benzethonium chloride, previously dried 2 hr under vac. at 80°, into 250 mL erlenmeyer. Dissolve in 80 mL HOAc and add 10 mL 6%  $\text{Hg}(\text{OAc})_2$  in HOAc. Add 3 drops crystal violet indicator and titr. with 0.1*N*  $\text{HClO}_4$  to same blue-green end point used in stdzn of  $\text{HClO}_4$ . Perform blank detn on 80 mL HOAc and 10 mL  $\text{Hg}(\text{OAc})_2$ , and correct vol. of titrant.

% Purity = (corrected titrant vol.  $\times N \times 44.81$ )/g benzethonium chloride

(g) *Benzethonium chloride std soln*.—0.005*N*. Accurately weigh ca 2.25 g dried benzethonium chloride and dil. to 1 L with  $\text{H}_2\text{O}$ .  $N$  = (g benzethonium chloride  $\times$  % purity)/448.1

(h) *Sodium lauryl sulfate (SLS)*.—Approx. 95% pure. Det. purity as follows: Accurately weigh ca 500 mg SLS, transfer to 250 mL vol. flask with  $\text{H}_2\text{O}$ , and dil. to vol. Pipet 25 mL into 250 mL g-s erlenmeyer. Add 50 mL  $\text{CHCl}_3$ , 10 mL 1*N*  $\text{H}_2\text{SO}_4$ , and 1 mL Me yellow indicator. Titr. with 0.005*N* benzethonium chloride as follows: Add 20 mL titrant, shake vigorously, and let layers sep. Add titrant in 1 mL increments, shaking vigorously after each addn until pink in  $\text{CHCl}_3$  layer begins to change to orange. (Emulsion will begin to break rapidly at this time.) Add titrant in 2 drop increments until  $\text{CHCl}_3$  layer changes to definite yellow. Make detn in duplicate. 1 mL 0.005*N* benzethonium chloride = 1.442 mg SLS.

(i) *Sodium lauryl sulfate (SLS) std soln.*—5  $\mu\text{g/mL}$ . Transfer SLS equiv. to 100 mg pure SLS to 1 L vol. flask with  $\text{H}_2\text{O}$  and dil. to vol. Transfer 5.0 mL to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

**20.132****Preparation of Standard Curve**

Pipet 0, 1, 3, 5, 10, and 15 mL aliquot SLS std soln into 125 mL separators. Dil. each to ca 25 mL with  $\text{H}_2\text{O}$ . Add 10 mL 0.1*N*  $\text{H}_2\text{SO}_4$  and 1.0 mL Azure A. Ext with two 20 mL portions  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . Drain each  $\text{CHCl}_3$  ext thru pledget of glass wool into 50 mL vol. flask. Dil. to vol., read *A* at 637 nm against  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ , and prep. std curve.

**20.133****Determination**

(Rinse all glassware several times with  $\text{H}_2\text{O}$  to eliminate all traces of detergent.)

(a) *Liquid and frozen egg white.*—Let frozen egg white thaw at room temp. Accurately weigh ca 20 g liq. egg white into beaker and transfer to 500 mL g-s erlenmeyer with 400 mL  $\text{H}_2\text{O}$ . Swirl gently ca 1 min and let stand 1 hr with occasional swirling. Add 400 mL alcohol and mix by gentle shaking. Heat mixt. on steam bath 15 min and shake at 3 min intervals to promote complete pptn. Let cool 45 min and filter thru Whatman No. 30 paper, using 11 cm buchner. Wash ppt in flask and on filter with three 50 mL portions alcohol. Transfer filtrate to 1 L vol. flask and dil. to vol. with alcohol. Pipet 2 aliquots, each contg 50  $\mu\text{g}$  SLS, into sep. 100 mL beakers and evap. to dryness on steam bath with current of air. Take up residues with  $\text{H}_2\text{O}$  and transfer each to 125 mL separator with several small portions  $\text{H}_2\text{O}$  to make total of ca 25 mL. To one add 1.0 mL 0.005*N* benzethonium chloride to serve as blank. Continue with each as in 20.132, beginning "Add 10 mL 0.1*N*  $\text{H}_2\text{SO}_4$  . . ." Read *A* of sample and blank against  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . Subtract blank *A* from sample *A*. Det. SLS from std curve.

(b) *Powdered egg white.*—Accurately weigh ca 2.5 g powd egg white into 300 mL g-s erlenmeyer and add 40 mL  $\text{H}_2\text{O}$ . Let stand 2 hr with occasional swirling. If egg white is not completely suspended after 1 hr, break up lumps with stirring rod and swirl at 5 min intervals until all egg white is suspended. After 2 hr, add 20 mL alcohol and shake gently 1 min. Heat mixt. on steam bath 0.5 hr, remove, and let cool 0.5 hr. Continue as in (a), beginning ". . . filter thru Whatman No. 30 . . ."

(c) *Flake dried egg white.*—Grind flakes in mortar to pass No. 20 sieve. Proceed as in (b).

**ENZYMES****Proteolytic Activity of Papain (38)—Official First Action****20.134****Reagents**

(a) *Casein soln.*—Make 6% soln of Hammersten casein (US Biochemical Corp, PO Box 22400, Cleveland, OH 44122) by rubbing 60 g with little  $\text{H}_2\text{O}$  in mortar and gradually adding 60 mL 1*N* NaOH and  $\text{H}_2\text{O}$  until vol. totals 1 L. Heat viscous soln 30 min in boiling  $\text{H}_2\text{O}$  bath, cool, and filter thru glass wool if necessary.

(b) *Citrate buffer soln.*—Prep. 0.2*M* monosodium citrate soln by partial neutzn of citric acid with NaOH.

(c) *Titration soln.*—Stdzd 0.1*N* alc. KOH.

(d) *Indicator.*—1% alc. thymolphthalein soln.

**20.135****Preparation of Sample**

(a) *Unactivated.*—If enzyme prepn is solid, grind to smooth paste in small mortar with little freshly boiled, cold  $\text{H}_2\text{O}$ . Suspend

in cold boiled  $\text{H}_2\text{O}$  in proportion of 10 mg original prepn/mL  $\text{H}_2\text{O}$ . After 5–10 min centr. suspension and discard sediment.

(b) *Activated.*—Proceed as in (a), but use half-satd  $\text{H}_2\text{S-H}_2\text{O}$  (Caution: See 51.059) instead of boiled  $\text{H}_2\text{O}$ . After centrfg, incubate enzyme soln 1 hr at 40° to complete activation.

**20.136****Determination**

Place 10 mL casein soln and small charge of 4 mm diam. glass beads in each of several 125 mL g-s bottles, and bring bottles and contents to 40°. Add desired vol. of prepd enzyme soln, but  $\leq 4$  mL. If this amt is insufficient (see 20.137), prep. more concd soln of enzyme. Immediately add exactly 3 mL buffer soln (pH of system should be  $5.0 \pm 0.1$ ). Vigorously shake bottle few sec and place in const temp.  $\text{H}_2\text{O}$  bath at 40°.

Incubate 20 min at 40°, counting time from addn of buffer. Add 1 mL indicator and begin titrg with alc. KOH soln. As soon as deep blue appears, shake bottle until color is discharged or ppt is completely dissolved. (It is usually best to add alkali in ca 0.5 mL portions.) When all pptd casein dissolves, transfer soln to 400–500 mL flask and rinse bottle 2 or 3 times with alcohol, using total of 25 mL. Add enough KOH soln to restore blue; then add 175 mL boiling alcohol. Carefully add more KOH soln until pale but distinct blue persists in soln.

Make control titrn exactly as described, but do it immediately after addn of buffer, without any incubation time. Difference between titrn of undigested sample and that of digested sample is measure of proteolytic activity of enzyme.

**20.137****Calculation of Proteinase Unit**

For smaller amts of enzyme, extent of hydrolysis detd by above titrn is straight line function of amts of papain used. For accurate work, det. this straight line by making several titrns with different amts of enzyme. If amts of papain used are too large, straight-line relationship no longer holds; if they are too small, detn is inaccurate. Amts of enzymes giving titrn differences of 0.6–1.2 mL 0.1*N* KOH are recommended.

Unit of papain is amt of enzyme that produces, under conditions outlined, titrn difference of 1 mL 0.1*N* KOH, detd either graphically or arithmetically. Value of original prepn is then expressed in units/mg, or as mg papain prepn necessary to make one unit.

**Pharmaceutical Manufacturers Association—  
Food Chemicals Codex—AOAC Method (39)  
Official First Action**

**20.138****Reagents**

(a) *Sodium phosphate soln.*—0.05*M*. Dissolve 7.1 g anhyd.  $\text{Na}_2\text{HPO}_4$  in enough  $\text{H}_2\text{O}$  to make 1 L. Add drop of toluene as preservative.

(b) *Citric acid soln.*—0.05*M*. Dissolve 10.5 g citric acid.  $\text{H}_2\text{O}$  in enough  $\text{H}_2\text{O}$  to make 1 L. Add drop of toluene as preservative.

(c) *Casein substrate.*—Disperse 5 g Hammersten-type casein in 250 mL 0.05*M*  $\text{Na}_2\text{HPO}_4$ . Place in boiling  $\text{H}_2\text{O}$  bath 30 min with occasional stirring. Cool to room temp. and add 0.05*M* citric acid to pH  $6.0 \pm 0.1$ . Stir soln rapidly and continuously during addn of citric acid to prevent pptn of casein. Dil. to 500 mL with  $\text{H}_2\text{O}$ . Prep. fresh daily.

(d) *Phosphate-cysteine disodium ethylenedinitrilotetraacetate buffer soln.*—Dissolve 3.55 g  $\text{Na}_2\text{HPO}_4$  in 400 mL  $\text{H}_2\text{O}$  in 500 mL vol. flask. Add 7.0 g  $\text{Na}_2\text{H}_2\text{EDTA}$  and 3.05 g cysteine.  $\text{HCl.H}_2\text{O}$ . Adjust to pH  $6.0 \pm 0.1$  with 1*N* HCl or 1*N* NaOH and dil. to vol. with  $\text{H}_2\text{O}$ . Prep. fresh daily.

(e) *Trichloroacetic acid (TCA) soln.*—30%. Dissolve 60 g trichloroacetic acid in  $\text{H}_2\text{O}$  and dil. to 200 mL with  $\text{H}_2\text{O}$ . (Caution: See 51.082.)

(f) *Papain std soln.*—Accurately weigh 100 mg USP Papain Ref. Std in 100 mL vol. flask and add buffer soln, (d), to dissolve. Dil. to vol. with buffer soln, (d). Further dil. 4 mL of this soln to 100 mL with buffer soln. Use within 30 min of prepn.

**20.139****Preparation of Sample**

Accurately weigh amt sample contg activity equiv. to 100 mg ref. std and proceed exactly as in prepn of papain std soln.

**20.140****Determination**

Into each of 12 g-s 100 mL vol. flasks, pipet 25 mL casein substrate. Label flasks in duplicate (tests are run in duplicate except for blanks)  $S_1$ ,  $S_2$ , and  $S_3$  for papain std soln and  $U_2$  for sample soln. Label remaining 4 flasks (blanks)  $S_{1B}$ ,  $S_{2B}$ ,  $S_{3B}$ , and  $U_{2B}$ .

Add 5, 2.5, and 0 mL buffer soln, resp., to flasks  $S_1$ ,  $S_2$ , and  $S_3$  and also to their resp. blanks  $S_{1B}$ ,  $S_{2B}$ , and  $S_{3B}$ . To  $U_2$  and  $U_{2B}$  add 2.5 mL buffer soln. Place all flasks in 40° H<sub>2</sub>O bath and allow 10 min to reach bath temp.

Into each of duplicate flasks  $S_1$ , pipet 5 mL papain std soln, noting 0 time upon release of pipet with simultaneous swirling of flask to mix. Stopper and replace in bath. Into 2 flasks labeled  $S_2$ , pipet 7.5 mL papain std soln and proceed as before. Repeat for 2 flasks  $S_3$  to which 10 mL papain std soln is added and for 2 flasks  $U_2$  to which 7.5 mL sample soln is added.

After exactly 60 min add 15 mL 30% TCA to all 12 flasks and shake vigorously. With 4 flasks to which no std or unknown solns were added, prep. blanks by pipetting, resp., 5 mL ( $S_{1B}$ ), 7.5 mL ( $S_{2B}$ ), and 10 mL ( $S_{3B}$ ) papain std soln, and 7.5 mL ( $U_{2B}$ ) sample soln. Replace all flasks in 40° bath 30–40 min and let pptd protein fully coagulate. Filter thru Whatman No. 42, or equiv., paper, refiltering ca first half of filtrate thru same filter (filtrates must be completely clear).

Read  $A$  of filtrates at 280 nm against respective blanks. Plot readings for  $S_1$ ,  $S_2$ , and  $S_3$  against enzyme concn of each corresponding level in terms of mg/mL of 50 mL total test mixt. By interpolation from this curve, taking into consideration diln factors, calc. potency of sample in USP Units of Papain Activity/mg =  $C \times (100/W) \times (100/4) \times (50/7.5) \times U$ , where  $C$  = mg/mL obtained from std curve,  $W$  = mg sample, and  $U$  = activity of ref. std in units/mg.

**20.141****Definition of Unit**

One unit of papain activity represents activity which releases equiv. of 1  $\mu$ g tyrosine from specified casein substrate, under conditions of assay and at enzyme concn which liberates 40  $\mu$ g tyrosine/mL test soln. USP Papain contains  $\geq 6000$  papain units/mg.

**MISCELLANEOUS****Acetone Peroxides (40)—Official Final Action****20.142 In Baking Premixes**

Accurately weigh ca 8 g sample into flat-bottom centrf. bottle, pipet in 100 mL H<sub>2</sub>O, and stir 10 min after making sure no lumps remain. Centrf. at ca 1500 rpm ca 10 min. Pipet 25 mL supernate into erlenmeyer, add 25 mL H<sub>2</sub>SO<sub>4</sub> (1+4), and let stand  $\geq 3$  min, swirling occasionally. Titr. to light pink that lasts >20 sec with std 0.1*N* KMnO<sub>4</sub> soln, **50.025–50.026**.

Total peroxides in g H<sub>2</sub>O<sub>2</sub> equiv./100 g premix  
= mL KMnO<sub>4</sub>  $\times$  normality  $\times 0.0170 \times 100/0.25 \times$  g sample.

**20.143 In Milling Premixes**

Accurately weigh ca 200 mg sample into erlenmeyer, add 50 mL H<sub>2</sub>SO<sub>4</sub> (1+9), let stand >3 min, stirring occasionally, and titr. with std 0.1*N* KMnO<sub>4</sub>, **50.025–50.026**, to light pink that persists >20 sec.

Total peroxides in g H<sub>2</sub>O<sub>2</sub> equiv./100 g premix = mL KMnO<sub>4</sub>  
 $\times$  normality  $\times 0.0170 \times 100/\text{g sample}$ .

**Qualitative Test**

(Acetone peroxides are extremely explosive. Do not ext more org. peroxides from adsorbents than necessary for test. *Caution:* See **51.070(b)**.)

**20.144****Apparatus**

(a) *Recording infrared spectrophotometer.*—Suitable for work from 2 to 16  $\mu$ m.

(b) *Rock salt plate.*—Or other support stable to acetone and acetone peroxides and transparent in 2–16  $\mu$ m region.

**20.145****Test**

Weigh sample contg ca 10 mg H<sub>2</sub>O<sub>2</sub> equiv. of acetone peroxides into g-s flask. Add ca 1 g anhyd. Na<sub>2</sub>SO<sub>4</sub> and 10 mL acetone for every g adsorbate. Shake 3 min, filter (Whatman No. 12 paper has been found satisfactory) or centrf. (for baking premix), and carefully evap. clear soln to ca 1 mL under vac. at room temp.

Under warm light and gentle current of dry warm air, add concd acetone ext dropwise to rock salt plate. When film of viscous liq. is visible on plate, place it in IR light path and, without recording, check  $T$  of peak at ca 12.1  $\mu$ m. If necessary, add addnl portions of ext to give 20–25%  $T$ . Set spectrophtr at acetone peak at ca 9.2  $\mu$ m. Let radiation pass thru sample on plate until raised pen reaches max.  $T$  (acetone has evapd). Then record spectrum of film on salt plate from 2 to 16  $\mu$ m.

Compare curve to one obtained from ref. acetone peroxides treated in same manner.

**Brominated Vegetable Oils****Gas Chromatographic Method (41)—Official Final Action**

(*Caution:* See **51.011, 51.018, 51.034, 51.039, 51.040, 51.045, 51.054, and 51.066**.)

**20.146****Principle**

Extnd brominated oil is methylated and detd by GLC, using internal std.

**20.147****Apparatus and Reagents**

(a) *Gas chromatograph.*—Varian Model 1740-10, or equiv., with flame ionization detector, strip chart recorder fitted with disk integrator, 0.9 m (3')  $\times$   $\frac{1}{8}$ " od stainless steel column packed with 3% JXR or SE-30 (Supelco, Inc.) on 80–90 mesh Anakrom ABS. Operating conditions: temps (°)—injector 260, detector 270, column programmed from 150 to 270 at 10°/min; He carrier gas 40 mL/min.

(b) *Solvents.*—Ether, distil before use; anhyd. benzene, distil from Na wire; anhyd. MeOH, prep. as follows: Place 5 g clean, dry Mg turnings and 0.5 g resublimed I in 2 L r-b Pyrex flask fitted with double surface reflux condenser. Add 50–75 mL com. anhyd. MeOH thru condenser and warm mixt. on 100° H<sub>2</sub>O bath until I disappears. As H is vigorously evolved, remove flask from H<sub>2</sub>O bath. If vigorous evolution of H does not take place, add 0.5 g more I and heat mixt. until all Mg is converted to methoxide. Add 900 mL MeOH and boil 30 min under reflux. Distil mixt., with exclusion of moisture, discarding first 25 mL distillate.

(c) *Sodium in anhydrous methanol*.—Clean ca 1 g Na metal in hexane, dry with filter paper, and dissolve in 100 mL anhyd. MeOH in 250 mL conical flask fitted with silica gel drying tube.

(d) *Methyl 9,10-dibromostearate (DBS) std soln.*—2.0 mg/mL. Prep. DBS by dissolving 500 mg Me oleate (Applied Science Laboratories, Inc.) in 15 mL distd ether in 100 mL erlenmeyer held at 0°. Stir mag. and add 0.15 mL Br dropwise over 20 min. Stir addnl 10 min at 0°. Transfer soln with addnl 30 mL ether to 250 mL separator contg 50 mL 10% aq. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, shake, let layers sep., and discard aq. layer. Wash ether layer successively with two 10 mL portions 2% aq. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> and two 10 mL portions H<sub>2</sub>O. Dry ether layer over anhyd. Na<sub>2</sub>SO<sub>4</sub> and evap. on rotary evaporator at 40°.

Dissolve 200 mg DBS in anhyd. benzene in 100 mL vol. flask and dil. to vol. with anhyd. benzene.

(e) *Methyl 9,10,12,13-tetrabromostearate (TBS) std soln.*—2.0 mg/mL. Prep. TBS as in (d), except use Me linoleate (Applied Science Laboratories, Inc.) and 0.30 mL Br. Prep. std soln as in (d).

(f) *Brominated vegetable oil (BVO) std soln.*—1.0 mg/mL. Dissolve 50 mg BVO (Dominion Products, Inc., 882 3rd Ave, Brooklyn, NY 11232) in acetone in 50 mL vol. flask and dil. to vol. with acetone.

(g) *Methyl pentadecanoate (MPD) internal std soln.*—1.0 mg/mL. Dissolve 100 mg MPD (Applied Science Laboratories, Inc.) in anhyd. benzene in 100 mL vol. flask and dil. to vol. with anhyd. benzene.

## 20.148

### Preparation of Standards

(a) *Methyl 9,10-dibromostearate and methyl 9,10,12,13-tetrabromostearate std solns.*—Pipet 3, 5, and 10 mL (6, 10, and 20 mg) DBS std solns into 3 sep. dry conical flasks and add 3, 5, and 10 mL (3, 5, and 10 mg) MPD std soln to each. Similarly prep. TBS-MPD solns. Treat each soln as follows: Evap. solv. with N at 40°. Add 25 mL 1% Na in MeOH and 12 mL anhyd. benzene, and reflux 1 hr. Cool, and transfer to 125 mL separator contg 50 mL H<sub>2</sub>O. Acidify with 2N H<sub>2</sub>SO<sub>4</sub> and ext with three 30 mL portions ether, using first 30 mL to rinse flask. Combine ether exts in second separator, wash with two 10 mL portions H<sub>2</sub>O, dry over anhyd. Na<sub>2</sub>SO<sub>4</sub>, filter, and evap. solv. on rotary evaporator at 40°. Dissolve residue in 3 mL ether.

(b) *Brominated vegetable oil.*—Pipet 5 and 10 mL BVO std soln (5 and 10 mg) into sep. dry conical flasks, add 1 and 2 mL MPD std soln (1 and 2 mg), resp., and evap. solv. with N at 40°. Proceed as in (a), beginning "Add 25 mL 1% Na in MeOH . . ."

## 20.149

### Preparation of Sample

Decarbonate and mix by transferring several times from 1 beaker to another. Transfer 280 mL sample to 500 mL separator, sat. thoroly with NaCl, and add 1 mL MPD std soln (1 mg). Ext with three 100 mL portions ether. Combine exts in second separator and wash successively with 50 mL 2N NaOH, 50 mL 2N HCl, and two 25 mL portions H<sub>2</sub>O. Dry ether layer over anhyd. Na<sub>2</sub>SO<sub>4</sub>, filter, and evap. on rotary evaporator at 40°. Quant. transfer residue with ether to clean, dry conical flask, and evap. ether with N at 40°. Proceed as in 20.148(a), beginning "Add 25 mL 1% Na in MeOH . . ."

## 20.150

### Determination

Inject duplicate portions methylated DBS, TBS, BVO std, and sample solns. Det. peak area (PA) with disk integrator. Correct apparent areas of both TBS and DBS for area of common peak a (Fig. 20:06) as follows: Assume PA<sub>a</sub> in TBS chromatograms is

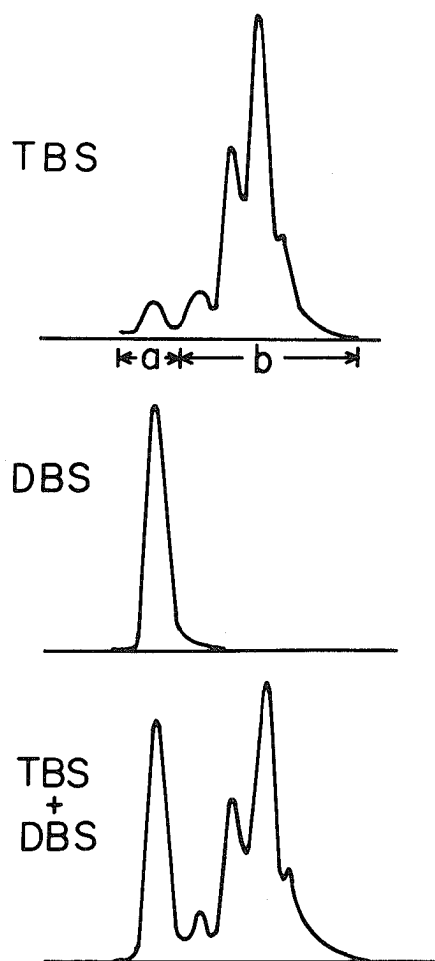

FIG. 20:06—Gas chromatograms of TBS, DBS, and TBS + DBS

5% of PA<sub>b</sub> and apparent PA<sub>DBS</sub> and PA<sub>TBS</sub> are 100 and 200 units, resp.

True DBS PA = 100 - 1/20 (200) = 90 units

True TBS PA = 200 + 1/20 (200) = 210 units

Det. av. response factors (RF) for each soln.

$$RF_{DBS \text{ or } TBS} = (\text{mg DBS or TBS}) \times PA_{MPD} / (\text{mg MPD} \times \text{true } PA_{DBS \text{ or } TBS})$$

(a) *Brominated vegetable oil (no sample) calculated from total peak areas.*—(Use for checking response factors, recoveries, and B, required for (b).)

$$\text{mg BVO} = ([PA_{16} + PA_{18} + (\text{true } PA \times RF)_{DBS} + (\text{true } PA \times RF)_{TBS}] \times \text{mg MPD}) / PA_{MPD}$$

where PA<sub>16</sub> and PA<sub>18</sub> = areas of C<sub>16</sub> and C<sub>18</sub> Me esters, resp.

(b) *Brominated vegetable oil in sample calculated from brominated derivatives only.*—

$$\text{mg BVO} = [(\text{true } PA \times RF)_{DBS} + (\text{true } PA \times RF)_{TBS} \times \text{mg MPD}] / (PA_{MPD} \times B)$$

where B = % (DBS + TBS) in BVO found by direct analysis (a).

### Sorbitol (42)—Official Final Action

(Apple and apple by-products contain naturally occurring sorbitol.) (Caution: See 51.011, 51.022, and 51.066.)

## 20.151

### Principle

Sorbitol is extd with MeOH, and acetate derivative is formed in presence of pyridine, extd with CHCl<sub>3</sub>, and detd by GLC.

## 20.152

**Apparatus**

(a) *Soxhlet extractor*.—Medium size (Corning No. 3740, Kimble No. 24071, or equiv.), with 33 × 80 mm extn thimble.

(b) *Gas chromatograph*.—Equipped with flame ionization detector, 1 mv strip chart recorder, and 1.8 m (6') × 4 mm id U-shaped glass column packed with 10% DC-200 on 100–120 mesh Gas-Chrom Q (Applied Science Laboratories, Inc.). Operating conditions: temps (°)—column 200 (or such that retention time of sorbitol acetate is 9–10 min), injector 230, detector 210; flow rates (mL/min)—N carrier gas 120, air 350–400, H optimal; sensitivity  $0.4 \times 10^{-9}$  amp for full scale deflection; or equiv. conditions so that acetate equiv. to 2.5 µg sorbitol will give ½ scale deflection.

## 20.153

**Reagents**

(a) *Diatomaceous earth*.—Celite 545, acid-washed.

(b) *Sorbitol*.—Reagent grade, or equiv. (Fisher Scientific Co. S-459).

## 20.154

**Extraction**

Place moist products in 60° forced-draft oven until dry (overnight drying is convenient). Chop dry sample in Hobart mixer. Weigh sample contg ca 400 mg sorbitol (usually ca 10 g), mix with 5 g Celite, and place in extn thimble. Place piece of glass wool on top of sample. Add 125 mL anhyd. MeOH to extn flask, and ext 2 hr at rapid boil. Quant. transfer MeOH ext to 200 mL vol. flask with MeOH and dil. to vol. with MeOH.

## 20.155

**Preparation of Standard Curve**

Accurately weigh ca 20, 40, 60, and 80 mg sorbitol into sep. 125 mL § 24/40 erlenmeyer. Add 3 mL pyridine and 10 mL Ac<sub>2</sub>O. Fit flask with air condenser and reflux 1 hr on steam bath. Add 60–80 mL H<sub>2</sub>O, mix, and cool. Ext with four 20 mL and one 15 mL portion CHCl<sub>3</sub>. Dil to 100 mL with CHCl<sub>3</sub> in vol. flask. Inject ca 5 µL into gas chromatograph.

Prep. std curve by plotting response (sq mm/µL injected) against mg sorbitol initially weighed.

## 20.156

**Determination**

Pipet 25 mL MeOH ext into 125 mL § 24/40 erlenmeyer. Evap. ext to dryness on steam bath with current of air. Proceed as in 20.155, beginning "Add 3 mL pyridine . . .", dissolving residue as completely as possible. Calc. % sorbitol as follows:

$$\% \text{ Sorbitol} = (\text{mg from std curve} \times 0.8) / \text{g sample}$$

**NONNUTRITIVE SWEETENERS****Identification (43)—Official First Action**

(Applicable to nonalcoholic beverages)

## 20.157

**Apparatus**

(a) *Thin layer apparatus*.—See 19.041.

(b) *Ultraviolet light*.—Capable of providing shortwave (254 nm) radiation (Spectronics Corp., 956 Brush Hollow Rd, Westbury, NY 11590, or equiv.).

## 20.158

**Reagents**

Prep. solns fresh on day of use.

(a) *Developing solv.*—*n*-BuOH-alcohol-NH<sub>4</sub>OH-H<sub>2</sub>O (40+4+1+9, by vol.).

(b) *Chromogenic agents*.—(1) Br in CCl<sub>4</sub>, 5% by vol. (Caution: See 51.047 and 51.049); (2) 0.25% fluorescein in dimethylfor-

mamide-alcohol (1+1); and (3) 2% *N*-1-naphthylethylenediamine.2HCl in alcohol.

(c) *Std mixture*.—50 mg Ca cyclamate, 10 mg Na saccharin, 4 mg dulcin, and 4 mg 5-nitro-2-propoxyaniline (P-4000) in 10 mL dil. alcohol (1+1). (5 µL = 25 µg cyclamate, 5 µg saccharin, 2 µg dulcin, and 2 µg P-4000.) Warm soln to dissolve dulcin, if necessary. Avoid contact with P-4000.

(d) *Silica gel*.—Adsorbosil-1 (Applied Science Laboratories, Inc.) or silica gel H (E. Merck, distributed by Brinkmann Instruments, Inc.).

## 20.159

**Preparation of Sample**

(Caution: See 51.011, 51.040, and 51.057.)

Decarbonate beverage by repeated shaking and pouring. To 50 mL sample in 125 mL separator, cautiously add 10 mL H<sub>2</sub>SO<sub>4</sub> (1+1). Cool, ext with two 50 mL portions pet ether (shake gently but thoroly), and discard pet ether. To aq. layer, cautiously add 5 mL 50% NaOH soln (w/w), cool, and ext with two 50 mL portions EtOAc. (Use 60 mL for cola samples to prevent emulsions.) Filter EtOAc exts thru EtOAc-washed cotton into beaker or flask with pouring lip. Evap. to 5–10 mL on steam bath, using air current, and transfer to graduated tube. (Do not let soln evap. to dryness before transfer. Compds may be difficult to redissolve.) Evap. soln in graduated tube to dryness on steam bath with air current. Dil. to 2.5 mL with NH<sub>4</sub>OH-H<sub>2</sub>O-alcohol (5+5+10) and mix thoroly. (Insol. residue in tube will not interfere with detn.)

## 20.160

**Preparation of Plates and Tank**

Slurry 35 g Adsorbosil-1 with 50 mL H<sub>2</sub>O or 30 g silica gel H with 75–80 mL H<sub>2</sub>O, and apply as 0.25 mm layer to five 8 × 8" (20 × 20 cm) plates. Dry plates > 1 hr at room temp. Do not dry in oven. Do not store in desiccator cabinet. Score layer 5 mm from each side edge and remove 5 mm band of adsorbent from bottom edge of layer. Use plates within 36 hr after prepn.

Line developing tank with absorbent paper. Pour 25 mL developing solv. into tank, wetting paper. Place V-shaped trough in tank and add 25 mL developing solv. to trough. (Alternatively, put developing solv. in tank to ca 1 cm.) Place lid on tank, seal, and let stand ca ½ hr to sat. tank atm.

## 20.161

**Determination**

(Caution: See 51.016 and 51.017.)

Mark TLC plate at side edges only, 2.5 cm from bottom to designate spotting line. Mark dotted line 10 cm above spotting line. Spot total of 5 µL each of std mixt. and sample (*Level 1*). Dil. sample to 5 mL with NH<sub>4</sub>OH-H<sub>2</sub>O-alcohol (5+5+10) and spot 5 µL (*Level 2*). Place spots ≥ 2 cm apart and 2 cm from edges. Spot 1 µL at a time and use warm-air blower to dry spot between applications to confine spot diam. Use same technic to spot sample and std. (Total vol. spotted should be ≤ 5 µL. Use mixed std rather than superimposed single stds.)

Place plate in tank and develop to 10 cm line (ca 1 hr). Dry plate in hood until layer is no longer translucent (ca 10 min). View under shortwave (254 nm) UV. Outline fluorescent saccharin spot at *R<sub>f</sub>* ca 0.5. (Spot may be crescent-shaped if large amt of cyclamate is present.) In hood, spray chromogenic agents (1) and (2), lightly to moderately, in immediate succession, on plate until cyclamate std appears as pink spot at *R<sub>f</sub>* ca 0.3–0.4. P-4000 is brown-pink spot at *R<sub>f</sub>* ca 0.85. Spray chromogenic agent (3) on plate until background pink fades to light yellow; contrast of cyclamate and P-4000 improves and at *R<sub>f</sub>* ca 0.7 dulcin appears. Dulcin spot may be brownish-pink or blue,

depending on condition of spray reagents and concn of sweetener. Plate may be resprayed with chromogenic agent (3) to restore contrast if pink background reappears.

### CYCLOHEXYLSULFAMATE (CYCLAMATE) SALTS

#### Qualitative Test—Official First Action

(SO<sub>2</sub> will interfere with test. Verify absence by 20.105.)

#### 20.162 Sodium Nitrite Test

Add 2 g BaCl<sub>2</sub> to 100 mL sample or aq. ext, prepd as in 20.093(c). Let stand 5 min and filter. Acidify with 10 mL HCl and add 0.2 g NaNO<sub>2</sub>. White ppt of BaSO<sub>4</sub> indicates presence of cyclohexylsulfamate.

#### 20.163 Quantitative Method (44)—Official Final Action

(Applicable to aq. solns and clear carbonated beverages; if caramel is present, confirm cyclamates by 20.157–20.161. SO<sub>2</sub> will interfere; verify absence by 20.105.)

To 100 mL soln contg 10–300 mg Na or Ca cyclohexylsulfamate add 10 mL HCl and 10 mL 10% BaCl<sub>2</sub> soln. Stir and let stand 30 min. If ppt forms, filter and wash with H<sub>2</sub>O. To filtrate or clear soln, add 10 mL 10% NaNO<sub>2</sub> soln, stir, cover with watch glass, and heat on steam bath ≥2 hr. Stir up ppt 3 times at 0.5 hr intervals. Remove from steam bath and leave in warm place overnight. Collect ppt on tared gooch, wash, and dry on asbestos mat over flame ≥10 min. Ignite, cool in desiccator, and weigh.

Wt BaSO<sub>4</sub> × 0.8621 = Na cyclohexylsulfamate;

Wt BaSO<sub>4</sub> × 0.9266 = Ca cyclohexylsulfamate.2H<sub>2</sub>O.

### Cyclohexylamine (CHA) in Cyclamates and Artificially Sweetened Products (46)

#### Official First Action

(Caution: Use effective fume removal device when evapg or distg CH<sub>2</sub>Cl<sub>2</sub>.)

#### 20.168

#### Apparatus

(Glassware Cat. numbers refer to Kontes Glass Co., unless otherwise noted.)

(a) *Evaporative concentrator*.—Kuderna-Danish, 250 mL, with § 24/40 column connection and § 19/22 lower joint (K-570000).

(b) *Concentrator tube*.—Size 425, § 19/22 joint, 4 mL; from 0 to 2 mL subdivided in 0.1 mL (K-570050), with § 19/22 pennyhead stopper (K-850500).

(c) *Distilling column*.—Snyder, size 121, column length 150 mm with § 24/40 joint (K-503000).

(d) *Funnel*.—Buchner, 60 mL, coarse porosity disk (K-955000).

(e) *Separator*.—250 mL, with Teflon stopcocks (K-636030).

(f) *Microliter syringes*.—10 and 100 µL (Hamilton Co., or equiv.).

(g) *Distillation apparatus*.—(1) 1 and 2 L r-b boiling flasks with § 24/40 joint (K-601000); (2) connecting adapter with § 24/40 and 10/30 joints (K-167000); (3) Liebig condenser, 200 mm jacket length with § 24/40 joints (K-447000); (4) adapter, bent 105° with § 24/40 joint (K-157000); (5) thermometer with § 10/30 joint, range –10 to 110°, 3" immersion (K-871000).

(h) *Heating mantles*.—Hemispherical, for 1 and 2 L r-b flasks. (Use with variable transformer heat control.)

(i) *Gas chromatographs*.—For convenience, 2 instruments may be used, one for actual detns and second for trapping: (1) Perkin-Elmer Corp., Model 881 (current equiv. model is 3920B), with dual flame ionization detectors, or equiv., with following column and conditions: 12' (3.7 m) × 1/8" stainless steel column packed with 10% Carbowax 20M (solid polyethylene glycols)

plus 2.5% NaOH on 90–100 mesh Anakrom SD support. Condition columns 16 hr at 200° while maintaining carrier gas (N) flow of 40 mL/min. Maintain following parameters thruout analyses: temps (°)—column 100, injector 180, detector 175; carrier gas flow 72 mL/min, H flow 35 mL/min, air flow 550 mL/min and attenuation range 5–50× at 1 × 10<sup>-11</sup> amp into 1 mv full scale recorder. (2) Hewlett-Packard Model 5750B research chromatograph (or 5800 series), with dual flame ionization detectors and effluent splitters (Hewlett-Packard, Rt 41, Avondale, PA 19311, or equiv.), and with same column and conditions used with Perkin-Elmer Model 881 above, with following exceptions: Carrier gas flow 75 mL/min thru column and 62 mL/min thru splitter, and attenuation range 640× at 2 × 10<sup>-14</sup> amp into 1 mv full scale recorder.

(j) *Infrared spectrophotometer and accessories*.—Perkin-Elmer Corp., Model 621 with 6× beam condenser and micro KBr attachment, or equiv.

(k) *Septum*.—Silicone rubber, diam. 19 mm (K-774150).

(l) *Aluminum foil*.—Ordinary household foil.

(m) *Microsampling die and accessories*.—KBr Ultra Micro Die, Perkin-Elmer Corp., or equiv. See Fig. 20.07. (1) *Metal funnel*.—Perkin-Elmer Corp., No. 186–1044, consisting of metal disk ca 2 cm diam. × 5 mm thick, with hole 1.5 mm diam. bored thru center of disk. Upper part of hole is flared out to width of 5–7 mm to form funnel. (2) *Plunger*.—Perkin-Elmer Corp., No. 186–1041, consisting of metal rod, one end of which has been turned down to 1.5 mm diam. to fit into funnel. (3) *Two polished stainless steel blocks*.—Approx. 5 cm diam. and 20–25 mm thick. (4) *Micro syringe*.—With end of needle cut off flat. (5) *Punch*.—Made from syringe needle 2 mm od with end cut off flat. (6) *Press*.—Capable of delivering 25,000 psi.

#### 20.169

#### Reagents

(a) *Methylene chloride*.—Certified reagent (D-37, Fisher Scientific Co.), or equiv. Redistil and check purity before use as follows:

Purify by distg in all-glass app. with air-cooled reflux condenser (ca 30 cm long) between distg flask and H<sub>2</sub>O-cooled condenser. Provide collection flask with drying tube to protect distd solv. from moisture. Distil solv. in 2 L lots, discard first 200 mL distillate, and collect next 1.5 L for use.

*Purity test*.—Place 80 mL (vol. used in actual extn) into 250 mL Kuderna-Danish concentrator fitted with 4 mL concentrator tube and conc. to 0.5 mL as in 20.170(a). Inject 1 µL into gas chromatograph. Solv. must be free of interfering peaks.

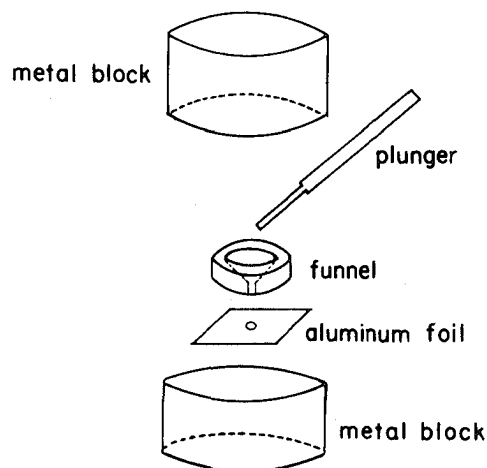

FIG. 20.07—Microsampling die

In addn to purity test, test solv. before use by concg 80 mL  $\text{CH}_2\text{Cl}_2$  contg 120  $\mu\text{g}$  CHA to 1.0 mL in Kuderna-Danish concentrator. If recovery of CHA is <90%, purify solv. by following alkali treatment and retest as above, after passage thru 30 g anhyd.  $\text{Na}_2\text{SO}_4$  prewetted with 25 mL alkali-treated solv. prep'd as follows: Dissolve 40 g NaOH in 200 mL  $\text{H}_2\text{O}$  in 500 mL erlenmeyer and cool under tap water. Transfer soln to 500 mL separator and add 105 mL  $\text{CH}_2\text{Cl}_2$  (80 mL for extn and 25 mL for  $\text{Na}_2\text{SO}_4$  wash). Shake 3 min, let layers sep., and drain  $\text{CH}_2\text{Cl}_2$  (lower layer) for use.

(b) *Carbon disulfide*.—Spectral grade (MC/B Manufacturing Chemists CX393, or equiv.).

(c) *Hydrochloric acid*.—6N (approx.). Transfer 50 mL HCl to 100 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ .

(d) *Sodium hydroxide*.—10N (approx.). Add 60 mL  $\text{H}_2\text{O}$  to 40 g NaOH.

(e) *Cyclohexylamine (CHA)*.—99.6%, bp 132–134° (Eastman Kodak Co., or equiv.). Prep. std solns as follows: (1) *For cyclohexylamine analysis of dietetic beverage and food products*.—Weigh 60 mg CHA into 50 mL vol. flask and dil. to vol. with redistd  $\text{CH}_2\text{Cl}_2$  (1.2 mg/mL). Transfer 20 mL of this soln to 200 mL vol. flask and dil. to vol. with redistd  $\text{CH}_2\text{Cl}_2$  (120  $\mu\text{g}$ /mL). Also, prep. 1.0 and 1.2 mg/mL CHA stds in  $\text{H}_2\text{O}$ . Transfer 8 and 10 mL of these solns, resp., to 200 mL vol. flasks and dil. to vol. with  $\text{H}_2\text{O}$  (40 and 60  $\mu\text{g}$ /mL, resp.). (2) *For cyclohexylamine analysis of artificial sweetener concentrates (liquid and dry) and cyclamates*.—Weigh 50 mg CHA into 50 mL vol. flask and dil. to vol. with redistd  $\text{CH}_2\text{Cl}_2$ . Transfer 10 and 20 mL aliquots to 200 mL vol. flasks and dil. to vol. with redistd  $\text{CH}_2\text{Cl}_2$  (50 and 100  $\mu\text{g}$ /mL, resp.). Also, prep. CHA std contg 1.0 mg/mL in  $\text{H}_2\text{O}$ . Transfer 5 and 10 mL of this soln to 200 mL vol. flasks and dil. to vol. with  $\text{H}_2\text{O}$  (25 and 50  $\mu\text{g}$ /mL, resp.).

(f) *pH test papers*.—Ranges 9–14 (No. 708) and 0–11 (No. DJ905, Micro Essential Laboratory, Inc., 4224 Ave H, Brooklyn, NY 11210).

(g) *Disodium dihydrogen ethylenedinitrilotetraacetate ( $\text{Na}_2\text{H}_2\text{EDTA}$ )*.—ACS.

## 20.170

### Isolation by Distillation

(Applicable to following artificially sweetened products: carbonated beverages and fruit juice drinks, dry beverage bases, canned fruits, and liq. and dry wt control formulations)

(a) *Carbonated beverages and fruit juice drinks*.—Transfer 300 mL aliquot of well mixed sample to 1 L boiling flask. Add boiling chips and enough 10N NaOH to obtain pH 14 as detd with test paper. Connect distn app. to boiling flask. Set up as receiver 250 mL beaker contg 2 mL 6N HCl and 2 boiling chips, and place under 105° adapter so that adapter tip is 5 cm above acid. Collect ca 35 mL distillate (ca 20 min). Mix by swirling and set beaker on hot plate; evap. to ca 3–5 mL at temp. just below bp.

Remove beaker from hot plate and cool under tap  $\text{H}_2\text{O}$ . Quant. transfer sample to 250 mL separator with four 25 mL portions  $\text{H}_2\text{O}$ . Add enough NaOH to obtain pH 14 as detd with test paper. Add 20 mL  $\text{CH}_2\text{Cl}_2$  and shake 2 min. Let layers sep. Filter  $\text{CH}_2\text{Cl}_2$  layer thru 30 g anhyd. granular  $\text{Na}_2\text{SO}_4$  (prewetted with 25 mL  $\text{CH}_2\text{Cl}_2$ ) into Kuderna-Danish evaporator with 4 mL concentrator attached. Immediately pass 20 mL  $\text{CH}_2\text{Cl}_2$  wash thru the  $\text{Na}_2\text{SO}_4$ . Repeat extn with two 10 mL portions  $\text{CH}_2\text{Cl}_2$ . Follow passage of each extn thru  $\text{Na}_2\text{SO}_4$  immediately with 10 mL portions  $\text{CH}_2\text{Cl}_2$ . Place SiC grains in concentrator tube, insert distg column into fitting of Kuderna-Danish concentrator, and carefully conc. solv. to ca 4 mL in steam bath. Remove app. from bath, let cool, and drain any remaining solv. in distg column and concentrator into concentrator tube. Conc. solv. in tube to 1.0 mL under stream

of ultra high purity N and reserve for injection into gas chromatograph.

(b) *Dry beverage bases*.—Dissolve content of each package according to directions. Transfer 300 mL well mixed sample to 1 L boiling flask and proceed as in (a).

(c) *Canned fruits*.—Place sample (fruit and sirup) in high-speed blender and blend ca 5 min. Transfer 300 g sample to 1 L boiling flask. Add 200 mL  $\text{H}_2\text{O}$  and enough 10N NaOH to obtain pH 14 as detd with test paper. Then add 10 drops Dow Corning *Antifoam Emulsion H-10* and distil as in (a), but collect 100 mL distillate in 400 mL beaker contg 2 mL 6N HCl and 2 boiling chips. Evap. acid soln to 3–5 mL, ext with  $\text{CH}_2\text{Cl}_2$ , and conc. combined exts as in (a).

(d) *Liquid weight control formulations*.—Transfer 200 g well mixed sample to 2 L boiling flask with 400 mL  $\text{H}_2\text{O}$ . Add enough 10N NaOH to obtain pH 14 as detd with test paper. Then add 7–8 drops *Antifoam Emulsion H-10* and mix. Distil as in (a). Collect 100 mL distillate in 400 mL beaker contg 2 mL 6N HCl and 2 boiling chips. Evap. on hot plate to 3–5 mL at temp. just below bp and, after cooling, quant. transfer to 250 mL separator with 100 mL  $\text{H}_2\text{O}$ . Adjust pH of soln to ca 1.0 with 6N HCl (test paper). Add 20 mL  $\text{CH}_2\text{Cl}_2$  and shake 2 min. Let layers sep. and discard  $\text{CH}_2\text{Cl}_2$  layer. Repeat extn with two 10 mL portions  $\text{CH}_2\text{Cl}_2$ . After discarding final  $\text{CH}_2\text{Cl}_2$  wash, adjust pH to 14 with 10N NaOH as detd with test paper. Ext with  $\text{CH}_2\text{Cl}_2$  and conc. combined exts as in (a).

(e) *Dry weight control formulations*.—Transfer content of packet (ca 20 g) to 1 L boiling flask. Add 300 mL  $\text{H}_2\text{O}$  and dissolve by swirling. Then add boiling chips, adjust pH to 14 with 10N NaOH as detd with test paper, and add 7–8 drops *Antifoam Emulsion H-10*. Proceed as in (d).

## 20.171

### Isolation by Extraction

(Applicable to cyclamate salts and food sweetener preps (dry bases and liq. concs))

(a) *Sodium cyclamate*.—Weigh 25 g well mixed sample in 100 mL beaker. Using powder funnel, transfer to 250 mL separator. Wash beaker with two 25 mL portions hot  $\text{H}_2\text{O}$  (ca 90°) and transfer each portion to separator. Add 50 mL more hot  $\text{H}_2\text{O}$  and shake to dissolve cyclamate completely. Cool under tap  $\text{H}_2\text{O}$  to ca 30°. Add enough 10N NaOH to obtain pH 14 as detd with test paper. Ext with  $\text{CH}_2\text{Cl}_2$  and conc. combined exts as in 20.170(a).

(b) *Food sweetener preparations (liquid concentrates containing sodium cyclamate)*.—Weigh 25 g well mixed sample in 100 mL beaker and transfer to 250 mL separator. Wash beaker with four 25 mL portions  $\text{H}_2\text{O}$  and transfer each portion to separator. Shake to dissolve cyclamate completely. Add enough 10N NaOH to obtain pH 14 as detd with test paper. Ext with  $\text{CH}_2\text{Cl}_2$  and conc. combined exts as in 20.170(a).

(c) *Calcium cyclamate*.—Weigh 25 g well mixed sample in 100 mL beaker. Using powder funnel, transfer to 250 mL separator. Wash beaker with three 25 mL portions hot  $\text{H}_2\text{O}$  (ca 90°) and transfer each portion to separator. Shake to dissolve cyclamate completely. Dissolve 25 g  $\text{Na}_2\text{H}_2\text{EDTA}$  in 65 mL  $\text{H}_2\text{O}$  and 10 mL 10N NaOH on steam bath. Pour this soln into separator and mix. Add enough 10N NaOH to obtain pH 14 as detd by test paper. Cool under tap  $\text{H}_2\text{O}$  to ca 30°. Ext with  $\text{CH}_2\text{Cl}_2$  and conc. combined exts as in 20.170(a).

(d) *Food sweetener preparations (liquid concentrates and dry bases containing calcium cyclamate)*.—Weigh 25 g well mixed sample in 100 mL beaker and transfer to 250 mL separator. Wash beaker with four 25 mL portions  $\text{H}_2\text{O}$  and transfer each portion to separator. For dry bases, use 25 mL portions hot  $\text{H}_2\text{O}$  (ca 90°) for transfer and shake funnel to dissolve dry base

completely. Dissolve 2.5 g  $\text{Na}_2\text{H}_2\text{EDTA}$  in 20 mL  $\text{H}_2\text{O}$  on steam bath, pour soln into separator, and mix. Add enough 10N NaOH to obtain pH 14 as detd by test paper. (For dry bases, cool separator under tap  $\text{H}_2\text{O}$  to ca  $30^\circ$ .) Ext with  $\text{CH}_2\text{Cl}_2$  and conc. combined exts as in 20.170(a).

## 20.172

**Gas Chromatography and Confirmation by Infrared Spectrophotometry**

Inject 1  $\mu\text{L}$   $\text{CH}_2\text{Cl}_2$  soln of sample ext into column. Det. presence and amt of CHA by comparing with appropriate aliquots of std solns injected directly into gas chromatograph. To confirm identity, install effluent splitters (use 5:1, vent: detector) and special triple laminated septa, and assemble collection trap as shown in Fig. 20:08. (Note: All glassware and associated equipment must be scrupulously clean.) Conc.  $\text{CH}_2\text{Cl}_2$  ext, 20.170(a), under N stream without heat to 0.1 mL (100  $\mu\text{L}$ ) and det. total CHA content. When  $<50 \mu\text{g}$  is present, inject 80  $\mu\text{L}$  into column. Collect peak effluent corresponding to retention time for CHA in 60  $\mu\text{L}$   $\text{CS}_2$  (previously cooled in solid  $\text{CO}_2$ ). Rinse connection tube with two 10  $\mu\text{L}$  portions  $\text{CS}_2$  into collection trap, stopper, and place in desiccator 10 min. Remove collection trap, add 3 mg anhyd. KBr, and remove excess  $\text{CS}_2$  under vac. at 64 cm.

For samples contg  $\geq 50 \mu\text{g}$  CHA, inject 50  $\mu\text{L}$   $\text{CH}_2\text{Cl}_2$  soln into column, collect appropriate effluent in 100  $\mu\text{L}$   $\text{CS}_2$ , and continue as above.

To prep. KBr disk (see Fig. 20:07), fold Al foil to provide 16 thicknesses and punch 2 mm hole thru it with punch. Place folded foil on steel block and place funnel, centered on hole, on foil. Firmly pack small portion KBr from collection trap into foil by use of plunger and funnel. Rub walls of collection tube with 2 mg powd KBr to ensure complete removal of the dithiocarbamate. Transfer this KBr loosely on top of thin layer of KBr in hole, tamp lightly, and carefully lift off funnel. Place second steel block on top of Al foil, and apply pressure of  $6.89 \times 10^7$  Pa (10,000 psi) for 30 sec. This produces transparent KBr disk suitable for IR spectroscopy.

Record IR spectrum and compare with ref. curve detd under identical conditions.

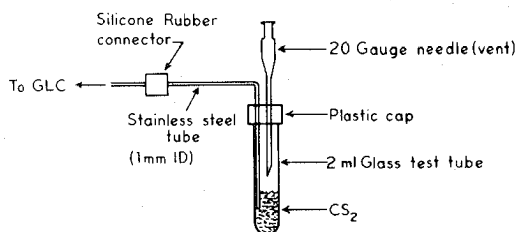

FIG. 20:08—GLC effluent collection trap for determination of cyclohexylamine

**DULCIN****20.173 Preparation of Sample—Official First Action**

(Caution: See 51.011 and 51.054.)

Ext 100 mL sample (made alk. with 10% NaOH soln, if necessary), or alk. aq. ext, prepd as in 20.093(c), with two or three 50 mL portions ether. Divide ether ext equally between 2 porcelain dishes, let ether evap. at room temp., and dry residues in oven at  $110^\circ$ .

**Qualitative Tests****20.174 Deniges-Tourrou Test (47)—Official First Action**

Moisten dry residue, 20.173, with  $\text{HNO}_3$  and add 1 drop  $\text{H}_2\text{O}$ . Presence of dulcin is indicated by formation of orange or brick-red ppt.

**20.175 Modified LaParola-Mariani Test (48) Official Final Action**

Expose dry residue, 20.173, to HCl gas for 5 min and add 1 drop *anisaldehyde*. Presence of dulcin is indicated by orange-red to blood-red color. Presence of 25 mg/L or kg original sample can usually be detected by this test.

**20.176 Quantitative Method (49)—Official First Action**

(Applicable to nonalcoholic beverages. Caution: See 51.011, 51.039, and 51.054.)

Pipet 50 mL sample into separator. If 5-nitro-2-propoxyaniline (P-4000) is present, ext with four 50 mL portions pet ether, shaking 2 min each time, and discard pet ether. Make aq. phase alk. to litmus with 10% NaOH soln and ext with four 100 mL portions ether, shaking 2 min each time. Combine exts, wash with 10 mL  $\text{H}_2\text{O}$ , and discard  $\text{H}_2\text{O}$ . Evap. ether in 400 mL beaker and dry residue 30 min at  $110^\circ$ .

Dissolve residue in ca 50 mL EtOAc, transfer to 100 mL vol. flask, dil. to vol. with 4 or 5 washings of the EtOAc, and mix. Read A in spectrophtr at 294 nm against redistd EtOAc. Det. amt of dulcin in final soln from previously prepd std curve and calc. to mg/L.

**5-NITRO-2-PROPOXYANILINE (P-4000)****Qualitative Tests****20.177 Organoleptic Test (50)—Official First Action**

(Caution: See 51.011, 51.039, and 51.073.)

Make alk. (pH 7.5–8.0) with 10% NaOH 200 mL liq. food or aq. ext of 200 g solid food or semisolid product, 20.185(c), and ext with three 25 mL portions pet ether. Wash combined exts once with 5 mL  $\text{H}_2\text{O}$ , transfer pet ether to small beaker or empty dish, let evap. spontaneously, and taste residue. Presence of 5 mg P-4000/L or kg original material may be detected by intensely sweet taste; or 12.5 mg/L or kg original material may be detected by its strong anesthetic effect.

**20.178 Diamine Test (51)—Official Final Action**

(Caution: See 51.011, 51.039, 51.047, and 51.073.)

Pipet 50 mL sample or aq. ext, 20.185(c), into separator, make alk. with 10% NaOH, and ext ca 1 min with 50 mL pet ether. Repeat extn with two 50 mL portions pet ether. Combine exts, wash with 10 mL  $\text{H}_2\text{O}$ , and discard  $\text{H}_2\text{O}$ . Transfer ext to small beaker and add 4 mL HCl (1+1). Evap. pet ether on steam bath. Add small piece mossy Sn and keep 5 min longer on steam bath. Decant soln into test tube; add, dropwise, satd  $\text{Br-H}_2\text{O}$ . Rose-red to deep burgundy-red soln is formed if P-4000 is present; this color is destroyed by excess Br.

**Quantitative Method (51)—Official Final Action**

(Applicable to nonalcoholic beverages)

**20.179****Reagent**

*1-Naphthol soln.*—Dissolve 50 mg 1-naphthol in 500 mL 1%  $\text{Na}_2\text{CO}_3$  soln. Prep. fresh daily and store in brown glass bottle.

**20.180****Preparation of Standard Curve**

Dissolve 100 mg 5-nitro-2-propoxyaniline in ca 150 mL 60% alcohol. Transfer to 250 mL vol. flask, dil. to vol. with 60% alcohol, and mix. Transfer 1.00, 2.00, 3.00, and 4.00 mL aliquots to 250 mL vol. flasks, dil. to vol. with H<sub>2</sub>O, and mix. Using 25 mL aliquots from each flask, proceed as in **20.181**, beginning "Ext with three 25 mL portions pet ether, . . ." Plot *A* against concn (0 to 0.16 mg/25 mL) final soln.

**20.181****Determination**

(Caution: See 51.011, 51.039, and 51.073.)

Pipet 20 mL sample into 250 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix. Transfer 25 mL aliquot to small separator, and add 10% NaOH soln, dropwise, until just alk. Ext with three 25 mL portions pet ether, shaking 1–2 min each time. Combine exts, wash with 5 mL H<sub>2</sub>O, and discard wash H<sub>2</sub>O. Transfer ext to small beaker, and add ca 10 mL H<sub>2</sub>O and 0.5 mL 0.1*N* HCl. Evap. pet ether on steam bath. Remove when few mL pet ether remain; let remaining pet ether evap. spontaneously. Cool soln to ca 20°, add 1.0 mL 0.125% NaNO<sub>2</sub> soln, and stir. After 1 min, add 5.0 mL 1-naphthol soln, mix, and dil. to 25 mL. Det. *A* at 515 nm within 1 hr against blank carried thru detn.

(mg P-4000/25 mL, from std curve) × 500 = mg/L.

**SACCHARIN****Qualitative Tests—Official Final Action****20.182 Organoleptic Test**

(Caution: See 51.011, 51.039, and 51.054.)

Acidify with HCl 50 mL nonalc. liq. food or aq. ext of 50 g solid or semisolid product, **20.185(c)**, and ext with three 25 mL portions ether. Wash combined ether exts once with 5 mL H<sub>2</sub>O, transfer to small beaker or evapg dish, let ether evap. spontaneously, and taste residue. (Presence of 20 mg saccharin/L or kg of original sample can usually be detected by its sweet taste.) Confirm by heating with NaOH and detecting salicylic acid formed thereby as in **20.183**.

**20.183 By Conversion to Salicylic Acid**

(Caution: See 51.011, 51.039, and 51.054.)

Acidify with HCl 50 mL nonalc. liq. food, or equiv. vol. aq. ext, **20.185**, and ext with 3 portions ether as in **20.182**. Dissolve residue remaining after evapn of ether in little hot H<sub>2</sub>O and test small portion of soln for salicylic acid as in **20.094** or **20.095**.

Dil. remainder of soln to ca 10 mL and add 2 mL H<sub>2</sub>SO<sub>4</sub> (1+3). Heat to boiling and add slight excess of 5% KMnO<sub>4</sub> soln dropwise; partly cool soln, dissolve ca 1 g NaOH in it, and filter mixt. into Ag dish (Ag crucible lids are suitable). Evap. to dryness and heat 20 min at 210–215°. Dissolve residue in H<sub>2</sub>O, acidify with HCl, and test ether ext for salicylic acid as in **20.094** or **20.095**. By this method all so-called "false saccharin" (J. Amer. Chem. Soc. **26**, 1627(1904)) and any salicylic acid naturally present (also added salicylic acid when not present in too large amt) are destroyed, whereas 5 mg saccharin/L is detected with certainty.

**20.184 Phenol-Sulfuric Acid Test (52)**

(Applicable to nonalc. beverages, semisolid preps, and baked goods. Caution: See 51.011, 51.039, 51.054, and 51.073.)

Prep. ether ext of sample as follows:

(a) *Nonalcoholic beverages*.—Add 3 mL HCl to 25 mL sample in separator. If vanillin is present, remove by extg with several

portions pet ether. Discard pet ether. Ext with 50, 25, and 25 mL ether-pet ether (1+1). Wash combined ether exts once with 5 mL H<sub>2</sub>O, remove major portion of solv., transfer to 30 mL beaker, and evap. at room temp.

(b) *Semisolid preparations*.—Transfer 25 g sample to 100 mL vol. flask with small amt hot H<sub>2</sub>O and add enough boiling H<sub>2</sub>O to make ca 75 mL. Let mixt. stand 1 hr, shaking occasionally. Then add 3 mL HOAc, mix thoroly, add slight excess (5 mL) of 20% *neut. Pb(OAc)<sub>2</sub> soln*, dil. to vol. with cold H<sub>2</sub>O, mix, let stand 20 min, and filter. Transfer ≥60 mL filtrate to separator and proceed as in (a).

(c) *Baked goods*.—Grind 25 g sample, mix thoroly with 50 g washed and ignited sea sand, and ext with pet ether in Soxhlet app. until essentially fat-free (1–2 hr). Transfer extd mass to 300 mL erlenmeyer, add 100 mL alcohol, and reflux on boiling H<sub>2</sub>O bath 30 min, shaking frequently. Filter thru buchner contg 7 cm Whatman No. 2 paper wet with alcohol. Transfer alc. filtrate to 100 mL beaker, evap. to ½ vol., add 50 mL H<sub>2</sub>O and enough 10% Na<sub>2</sub>CO<sub>3</sub> soln to make alk., and evap. to 50 mL. Transfer aq. soln to separator and proceed as in (a).

To residue remaining after evapn of solv. add 5 mL *phenol-H<sub>2</sub>SO<sub>4</sub> reagent* (pure colorless cryst. phenol dissolved in equal wt H<sub>2</sub>SO<sub>4</sub>) and heat 2 hr at 135–140°. Cool, dissolve in small amt of hot H<sub>2</sub>O, and pour into ca 250 mL H<sub>2</sub>O. Add small amt of Filter-Cel, let stand 3 hr or overnight, and filter. Make alk. with 10% NaOH soln and dil. to 500 mL. Magenta or reddish-purple color develops if saccharin is present. Yellow, buff, or pale salmon shade is not significant.

**Quantitative Methods****General Method I (53)—Official Final Action****20.185****Preparation of Sample**

(a) *Fruit juices and sirups*.—Transfer 100–200 g sample to 250 mL vol. flask with little H<sub>2</sub>O and dil. to ca 200 mL with H<sub>2</sub>O. Add 5 mL HOAc and mix. Add slight excess of 20% *neut. Pb(OAc)<sub>2</sub> soln*, mix thoroly, dil. to vol. with H<sub>2</sub>O, again mix thoroly, and filter.

(b) *Alcoholic liquids*.—Heat 100–200 mL liq. on steam bath to remove alcohol (usually done by evapg to ½ original vol.). With heavy sirups, dil. liq. with equal vol. H<sub>2</sub>O before beginning evapn. After removal of alcohol, transfer liq. to 250 mL vol. flask and proceed as in (a).

(c) *Solid or semisolid preparations*.—Transfer 50–75 g sample to 250 mL vol. flask with little hot H<sub>2</sub>O and add enough boiling H<sub>2</sub>O to make ca 200 mL. Let stand 2 hr, shaking occasionally. Add 5 mL HOAc, mix thoroly, add slight excess 20% *neut. Pb(OAc)<sub>2</sub> soln*, dil. to vol. with cold H<sub>2</sub>O, mix, let stand 20 min, and filter.

**20.186****Determination**

(Caution: See 51.011, 51.039, and 51.054.)

Transfer 150 mL filtrate, **20.185**, to separator, add 15 mL HCl, and ext with three 80 mL portions ether, shaking separator 2 min each time. Wash combined ether exts once with 5 mL H<sub>2</sub>O, remove ether by distn, and transfer residue to Pt crucible with little ether; or, if substances difficultly sol. in ether are present, use alternately small portions of H<sub>2</sub>O and ether. Evap. ether on steam bath, add to residue 2–3 mL 10% Na<sub>2</sub>CO<sub>3</sub> soln (or enough to make mixt. strongly alk.), rotate so that all saccharin is brought in contact with soln, and evap. to dryness on steam bath.

To dry residue add 4 g mixt. of equal parts of anhyd. Na<sub>2</sub>CO<sub>3</sub> and K<sub>2</sub>CO<sub>3</sub>. Heat gently at first and then to complete fusion 30 min. (Fusion may be conducted by closely fitting crucible into

hole cut into piece of heavy asbestos board so that  $\frac{1}{3}$  of crucible projects above asbestos, and heating lower portion of crucible by large Bunsen, Meker, or similar burner.) Cool, dissolve melt in  $\text{H}_2\text{O}$ , add ca 5 mL  $\text{Br-H}_2\text{O}$ , acidify with  $\text{HCl}$ , filter, wash paper with little  $\text{H}_2\text{O}$ , dil. filtrate and washings to ca 200 mL, heat to bp, and slowly add excess of 10%  $\text{BaCl}_2$  soln. Let mixt. stand overnight, collect  $\text{BaSO}_4$  on filter or on gooch, wash until  $\text{Cl}^-$  free, dry, ignite, cool, and weigh. Correct results thus obtained for any S present in fusion mixt. as found by blank detn. Saccharin = corrected wt  $\text{BaSO}_4 \times 0.7848$ .

Instead of mixed Na and K carbonates, 3–4 g  $\text{Na}_2\text{O}_2$  may be used for fusion. In this case Ni crucible must be used, and time of fusion may be reduced to 5 min. Sepn of little  $\text{PbCl}_2$  during extns does not interfere with accuracy of method.

#### 20.187 General Method II (By Sublimation) (54) Official First Action

(Caution: See 51.011, 51.039, 51.040, 51.049, and 51.054.)

Acidify 200 mL sample with 15 mL  $\text{HCl}$  and ext with three 50 mL portions  $\text{CCl}_4$ . Discard  $\text{CCl}_4$ , and ext aq. layer with three 80 mL portions ether. Let ether ext evap. to small vol. and transfer to sublimator with small amt of ether or alcohol. Evap. to dryness at room temp. or on  $\text{H}_2\text{O}$  bath, depending on whether ether or alcohol was used to transfer residue. Sublime residue 1 hr at 1–2 mm pressure and 140–160°. (Raise temp. so slowly that ca  $\frac{1}{2}$  hr is required to reach 140°.) Wash saccharin from condenser bulb of sublimator with warm alcohol into weighed beaker, and repeat sublimation until no further residue appears on condensing bulb. Evap. alcohol on  $\text{H}_2\text{O}$  bath, heat residue 2 hr at 100°, cool, and reweigh beaker.

#### 20.188 Special Method for Nonalcoholic Beverages (55) Official Final Action

(Caution: See 51.011, 51.039, and 51.054.)

Add 2 mL  $\text{HCl}$  to 50 mL sample in separator. Ext with two 50 mL portions ether. Filter ether exts thru cotton, and wash combined filtrates with ca 5 mL  $\text{H}_2\text{O}$  contg 1 drop  $\text{HCl}$ .

Sep. ether layer and evap. to dryness on  $\text{H}_2\text{O}$  bath. Add 5 mL  $\text{NH}_3$ -free  $\text{H}_2\text{O}$  and 6 mL  $\text{HCl}$  to residue, and evap. soln to ca 1 mL on hot plate, stirring constantly. Again add 5 mL  $\text{NH}_3$ -free  $\text{H}_2\text{O}$  and 6 mL  $\text{HCl}$ , and evap. to ca 1 mL. Dil. to 50 mL with  $\text{NH}_3$ -free  $\text{H}_2\text{O}$  and dil. 2 mL of this soln to 25 mL with  $\text{NH}_3$ -free  $\text{H}_2\text{O}$ . Add 1 mL Nessler reagent, 33.053(j), and compare with  $\text{NH}_4\text{Cl}$  stds in usual manner; 0.2921 g  $\text{NH}_4\text{Cl}$  = 1 g saccharin, insol. form ( $\text{C}_7\text{H}_5\text{NO}_3\text{S}$ ), and 1.317 g Na salt ( $\text{C}_7\text{H}_4\text{NNaO}_3\text{S} \cdot 2\text{H}_2\text{O}$ ). For convenience prep.  $\text{NH}_4\text{Cl}$  std equiv. to 200 ppm insol. form of saccharin.

## NUTRIENTS

### Monosodium Glutamate (56)—Official First Action

#### 20.189 Apparatus and Reagents

(a) *Chromatographic column*.—500  $\times$  22 mm od tube, 30 mL bed vol., with Dowex 50W-X8 ( $\text{H}^+$  form), 100–200 mesh.

(b) *Activated carbon*.—Darco G-60.

#### 20.190 Preparation of Sample

For products in dry form, reduce ca 40 g to powder in mortar and weigh 10 g sample into 250 mL beaker. For undild, concd soups or canned green beans, homogenize entire undild content of can in blender and weigh 20 g sample into 250 mL beaker. For consommé-type (clear, condensed) soup, weigh 20 g into 250 mL beaker.

Dil. sample to ca 70 mL with  $\text{H}_2\text{O}$  at room temp., and mix until all  $\text{H}_2\text{O}$ -sol. substances are in soln (ca 15 min). Add 6 g C and mix thoroly. (For products contg starch, also add 60 mL acetone to ppt starch and to aid sample soln.) Let stand 30 min. Filter with vac. thru 60 mL coarse fritted glass funnel contg asbestos pad. Wash flask and residue with six 25 mL portions  $\text{H}_2\text{O}$  or, if acetone was added, with six 25 mL portions acetone- $\text{H}_2\text{O}$  (1+1). Collect filtrate and washings in 400 mL beaker, add 2 drops  $\text{HCl}$  (1+2.5), and evap. on steam bath to ca 40 mL. ( $\text{HCl}$  prevents conversion of glutamic acid to pyrrolidone carboxylic acid.) Quant. transfer to 50 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

#### 20.191

#### Determination

Transfer 25 mL aliquot to prepd column and adjust flow to ca 0.5 mL/min. After all soln enters resin, wash column wall with ca 10 mL  $\text{H}_2\text{O}$ ; let wash pass into resin. Add 120 mL 0.8N  $\text{HCl}$  and maintain flow rate (0.8N  $\text{HCl}$  will elute any serine, threonine, and aspartic acid). After all 0.8N  $\text{HCl}$  passes into resin, add 170 mL 1N  $\text{HCl}$  and adjust flow to between 25 and 30 drops/min to elute glutamic acid; collect eluate in 400 mL beaker. (Any glycine present will elute after 200 mL 1N  $\text{HCl}$ .) Nearly neutze eluate with 50%  $\text{NaOH}$  and adjust potentiometrically to pH 7 with 0.1N  $\text{NaOH}$ .

Neutze 25 mL 37%  $\text{HCHO}$  to pH 7 with 0.1N  $\text{NaOH}$  and add to prepd neut. sample. Mix 10 min on mag. stirrer and titr. potentiometrically to pH 8.9 with 0.1N  $\text{NaOH}$ .

Det. blank by titrg to pH 8.9 mixt. of 25 mL neutzd  $\text{HCHO}$  and 170 mL 1N  $\text{HCl}$  neutzd to pH 7.

$$\% \text{ Glutamic acid} = [(S - B) \times N \times 0.147 \times 100] / W,$$

where  $S$  = mL  $\text{NaOH}$  used to titr. sample,  $B$  = mL  $\text{NaOH}$  used to titr. blank,  $N$  = normality of  $\text{NaOH}$ , and  $W$  = g sample in aliquot.

$$\% \text{ MSG} = \% \text{ glutamic acid} \times 1.15$$

Before using resin column again, remove any remaining amino acids by passing 150 mL 4N  $\text{HCl}$  thru column. Wash column with  $\text{H}_2\text{O}$  until  $\text{AgNO}_3$  soln gives neg. test for  $\text{Cl}^-$ .

## SOLVENTS

### Ethylene Dichloride and Trichloroethylene (57) Official Final Action

(Applicable to spice oleoresins)

#### 20.192

#### Apparatus

(All glassware must be  $\text{CHCl}_3$ -free; rinse with alcohol if necessary. Rinse pipets with alcohol after each use.)

(a) *Column*.—Porapak Q (50–80 mesh), available from Waters Associates, Inc. Pack 1.8 m  $\times$  6 mm od Al tube plugged at one end with glass wool, using slight vac. and light tapping to settle polymer beads. Add plug of glass wool to open end of column. Condition column 2 hr at 230°, passing N thru at 20 mL/min.

(b) *Gas chromatograph*.—Micro-Tek GC2503R or MT 220 gas chromatograph (Tracor Inc., 6500 Tracor Ln, Austin, TX 78721; current Models 550 or 222) or equiv., equipped with column, (a), Dohrmann Model C-200, C-200-A, or C-200-B microcoulometer (Dohrmann Division of Envirotech Corp.) connected to 1 mv (full-scale) strip chart recorder, combustion furnace, and Dohrmann T-200 titrn cell sensitive to halogens. Prep. Vycor tube in injection port with Pt gauze wrapped around loose plug of glass wool. Do not plug tube too tightly.

Operating parameters are as follows:

Coulometer, Mode II (low gain) and ca 200 ohms range, or range that provides ca half-scale deflection for 40  $\mu\text{L}$  injection of  $\text{C}_2\text{H}_4\text{Cl}_2$  std; removable inlet temp. 200°; column temp. 160°;

furnace temp. ca 825°; N flow 100 mL/min (measure with soap bubble flow meter); sweep 10–20 mL/min; O ca 25 mL/min.

**20.193****Reagents**

(Densities  $C_2H_4Cl_2$  and  $C_2HCl_3$  for converting from vol. to wt are 1.25 and 1.46, resp. Use absolute alcohol for all dilns.)

(a) *Internal std.*—(1) *Stock soln.*—Pipet 2.0 mL 1,2-dichloropropane into 200 mL vol. flask half filled with alcohol, immersing tip of pipet below surface of alcohol and then releasing contents. Wash pipet exterior with alcohol before withdrawing it from flask. Dil. to vol. and mix. (2) *Working std soln.*—Pipet 1.0 mL stock soln into 200 mL vol. flask half filled with alcohol, immersing pipet tip, as above, before releasing contents. Wash pipet exterior into flask, dil. to vol., and mix. Soln contains 0.05  $\mu$ L or 57.95  $\mu$ g 1,2-dichloropropane/mL alcohol.

(b) *Reference std.*—Prep. sep.  $C_2H_4Cl_2$  and  $C_2HCl_3$  stds as follows:

Pipet 2.0 mL chlorinated solv. into 200 mL vol. flask half filled with alcohol, immersing tip of pipet below surface of alcohol and then releasing contents. Wash pipet exterior with alcohol before withdrawing it from flask. Dil. to vol. and mix. Pipet 2.0 mL soln into 200 mL vol. flask as above, dil. to vol., and mix. Pipet 2.0 mL into 100 mL vol. flask as before, add 8.0 mL working internal std soln, and dil. to vol. Conc'n of stds:

Ethylene dichloride std = 2.50 ng  $C_2H_4Cl_2/\mu$ L and 4.64 ng 1,2-dichloropropane/ $\mu$ L.

Trichloroethylene std = 2.92 ng  $C_2HCl_3/\mu$ L and 4.64 ng 1,2-dichloropropane/ $\mu$ L.

**20.194****Determination**

Weigh 2.5 g well mixed oleoresin into 25 mL vol. flask, add 2.0 mL working internal std soln, and dil. to vol. with absolute alcohol. Shake vigorously ca 5 min.

Chromatograph duplicate portions, ca 30  $\mu$ L, in microcoulometric gas chromatograph set at prescribed conditions. Chromatograph duplicate portions of appropriate stds required to identify and quantitate. Vent ca 2 min after each injection and clean Vycor tube and contents after every 4 sample injections. (Det. venting time experimentally to release all alcohol.)

Approx. relative retention ratios relative to  $C_2H_4Cl_2$  = 1:  $C_2HCl_3$ , 1.6; 1,2-dichloropropane, 2.0.

Use relative retention ratios to identify chlorinated solv. residues found in samples. Inject 30  $\mu$ L absolute alcohol as solv. blank.

**20.195****Calculations**

Det. area of each peak and calc. as follows:

ppm chlorinated solv. residue =  $[(D \times I')/(I \times D')] \times C' \times (V/W)$ , where  $D$  = area of sample peak;  $D'$  = area of std peak;  $I$  = area of internal std peak from sample soln;  $I'$  = area of internal std from ref. std soln;  $C'$  = concn,  $\mu$ g/mL, of std chromatgd;  $V$  = mL to which sample is dild;  $W$  = g sample weighed.

## 21. Food Additives: Indirect

### Polycyclic Aromatic Hydrocarbons and Benzo[a]pyrene (7) Official Final Action

(Caution: See 51.011, 51.016, 51.039, 51.040, 51.045, 51.062, and 51.066.)

#### 21.001

#### Principle

Polycyclic aromatic hydrocarbons are extd from comminuted food sample after saponification with alc. KOH, purified by solv. partition and column chromatgy, sepd by TLC, detd by UV spectrophotometry, and confirmed by spectrophotofluorometry.

#### 21.002

#### General Instructions

Because of sensitivity of method, possibility of errors from contamination is great. All glassware must be thoroly cleaned to remove all org. matter such as oil, grease, detergent residues, etc. Do not use grease on stopcocks or joints. Rinse all glassware with purified solvs immediately before use. Because these compds are somewhat susceptible to photooxidn, perform detn as far as possible under subdued light and store std solns in low actinic flasks. Use care in prep g stds and handling exts, since some of these compds are carcinogenic.

#### 21.003

#### Apparatus

(a) *Separators*.—125, 500, 1000, and 2000 mL, with Teflon stopcocks.

(b) *Evaporation flasks*.—125, 250, and 1000 mL all-glass flasks (Kontes Glass Co., No. K-617250, or equiv.) with  $\frac{1}{8}$  24/40 wash bottle stopper (No. K-331751, or equiv.) having inlet and outlet tubes to permit passage of N across surface of liq. to be evapd. Inlet tube of stopper used to convey N is cut off 2 cm below joint, and outlet tube connected to vac. is bent downward at 45° angle to prevent backflow of condensate into flask.

(c) *Boiling flask*.—1 L r-b, with  $\frac{1}{8}$  24/40 joint and pouring lip.

(d) *Condenser*.—Friedrich-type with  $\frac{1}{8}$  24/40 joint.

(e) *Chromatographic tube*.—230 × 38 mm id, with coarse porosity fritted glass filter.

(f) *Pressure filter*.—30 mL, fine porosity, with  $\frac{1}{8}$  24/40 outer joint (Kontes Glass Co., No. K-953100, or equiv.) and adapter with  $\frac{1}{8}$  24/40 inner joint (Kontes Glass Co., No. K-183000, or equiv.) for connection to N cylinder.

(g) *Nitrogen cylinder*.—H<sub>2</sub>O-pumped purity N, or equiv., in cylinder with regulator and valve to control flow at 5 psig.

(h) *Heating mantle*.—Elec., hemispherical, for 1 L, r-b flask with variable transformer heat control.

(i) *Ultraviolet equipment*.—(1) *Lamps*.—Longwave, 3660Å; shortwave, 2537Å. (2) *Chromato-Vue cabinet*.—Available from Ultra-Violet Products, Inc.

(j) *Recording spectrophotometer and accessories*.—Cary 11 (current Models Cary 14 and 17, Varian Instrument Division), or equiv., with fused rectangular quartz cells, optical path 10 ± 0.005 mm, 1.5 mL (Optical Cell Co., Inc., 10792 Tucker St, Beltsville, MD 20705, No. 2-203 Q-QUV (Tol. A), or equiv.).

(k) *Spectrophotofluorometer and accessories*.—Aminco-Bowman with 1P28 photomultiplier tube and slit arrangement No. 2 (American Instrument Co., No. 4-8202, or equiv.); fused rectangular quartz cells (Optical Cell Co., Inc., No. 5-501 QS-QUV, or equiv.).

(l) *Thin layer chromatographic apparatus*.—(Available from Brinkmann Instruments, Inc.). (1) Glass plates, 10 × 20 cm (No.

25-10-110-3); (2) applicator, adjustable, Model S-II (No. 25-09-050-1); (3) mounting board, Plexiglas, std size for plate up to 20 cm wide (No. 04-10-000-0); (4) drying rack (No. 25-09-150-7); (5) developing tank, std, rectangular, 22 deep × 8.5 wide × 20.5 cm long (No. 04-10-080-8); (6) desiccating storage cabinet, stainless steel, 30 wide × 25 cm deep (No. 04-11-500-7).

(m) *Dipping tank*.—Type 302 stainless steel, capacity 370 mL; inside dimensions  $8\frac{3}{8} \times \frac{3}{16} \times 8\frac{3}{8}$ ", with cover (Arthur H. Thomas Co., No. 2749-H50, or equiv.).

(n) *Syringe*.—50  $\mu$ L (Hamilton Co., Inc., Type 705N, or equiv.).

#### 21.004

#### Reagents

Distil all reagents, where specified, with use of air-cooled, 30 cm reflux condenser between distg flask and H<sub>2</sub>O-cooled condenser. Use 2 L lots, discarding first 200 mL distillate and collecting next 1600 mL for use.

Purify isooctane, benzene, and MeOH to meet following test:

To specified vol. solv. in 250 mL evapn flask, add 1 mL purified *n*-hexadecane and place container on steam bath. Insert tube assembly, and connect inlet tube to N supply and outlet tube to solv. trap and vac. liné. Discontinue evapn when  $\leq 1$  mL residue remains. (To residue from benzene, add 10 mL purified isooctane, reevap., and repeat once to ensure complete removal of benzene.) Add 4.0 mL isooctane to 1.0 mL *n*-hexadecane residue. Det. A in 1 cm path length cell (1.5 mL) against isooctane as ref.; A of soln of solv. residue (except for MeOH) must be  $\leq 0.01$ /cm path length between 250 and 400 nm. For MeOH, A must be  $\leq 0.03$ /cm path length between 250 and 275 nm;  $\leq 0.015$  between 275 and 300 nm;  $\leq 0.010$  between 300 and 350 nm; and 0.00 between 350 and 400 nm.

(a) *Isooctane (2,2,4-Trimethylpentane)*.—Purify by distn or by passing thru column of activated silica gel, (k)(2), ca 90 long × 5–8 cm id. Use 180 mL for test.

(b) *Benzene*.—ACS. Purify by distn. Use 150 mL for test.

(c) *Hexadecane*.—99%, olefin-free. Purify by percolation thru column of activated silica gel, (k)(2). Det. A of 1 mL in 1 cm cell against isooctane as ref.; A must be 0.00/cm path length between 250 and 400 nm.

(d) *Methanol*.—ACS. Purify as follows: Reflux 2 L MeOH with 10 g KOH and 25 g Zn dust 3 hr. Distil thru air-cooled reflux condenser connected to H<sub>2</sub>O-cooled condenser. Provide collection flask with drying tube to protect distd solv. from moisture. Use 50.0 mL for test.

(e) *Alcohol*.—USP. Redistil before use.

(f) *Toluene*.—ACS. Redistil before use. (Caution: Flammable liq.)

(g) *Dimethyl sulfoxide (DMSO)*.—Spectroquality (MC/B Manufacturing Chemists, MX1457, or equiv.). (Caution: See 42.124(c).)

(h) *Acetylated linters powder*.—21% acetylated (S&S No. 124/21 ac, or equiv.).

(i) *Florasil*.—60–100 mesh (available from Fisher Scientific Co., No. F-100, or equiv.). Place 300 g Florasil in 1 L g-s erlenmeyer. Add 700 mL redistd MeOH, stopper, and shake 1 min, removing stopper periodically to release pressure. Transfer slurry to 600 mL coarse porosity fritted buchner and let drain by gravity. Wash flask with three 35 mL portions redistd MeOH and pass thru buchner. Wash adsorbent in funnel with addnl 100 mL redistd MeOH and let drain. Apply vac. to remove most of MeOH. Transfer treated Florasil to tray lined with Al foil (free

of rolling oil). Dry in vac. oven (66–71 cm; 26–28"; 88–94 kPa) at 50° overnight. Store adsorbent in amber bottle.

Test prep'd adsorbent before use as follows: Pour 10 g treated Florisil into clean 30 mL coarse porosity fritted glass funnel (30 mm diam.). Place 15 g anhyd.  $\text{Na}_2\text{SO}_4$  on adsorbent and wash with 50 mL purified isooctane. Prep. 1.0  $\mu\text{g}/\text{mL}$  soln of benzo[a]pyrene in isooctane. Pipet 1 mL soln onto anhyd.  $\text{Na}_2\text{SO}_4$ , let filter into 125 mL evapn flask, and wash adsorbent with four 20 mL portions isooctane, letting column drain completely between washes. Remove and retain first evapn flask and replace with second 125 mL evapn flask. Elute benzo[a]pyrene from column, using four 25 mL portions redistd benzene; let column drain completely between washes. Add 1.0 mL hexadecane to each eluate in the 2 evapn flasks. Evap. under stream of N on steam bath to residue of 1 mL hexadecane. Add 5 mL isooctane to residue from benzene eluate in second evapn flask and re-evap. Repeat once to ensure complete removal of benzene. Transfer the 1.0 mL residue to 1.0 cm path length cell (1.5 mL capacity) and record *A* with recording spectrophtr from 350 to 400 nm, against isooctane in ref. cell. No benzo[a]pyrene should be present in first (isooctane) eluate, and 95–100% of added benzo[a]pyrene should be found in benzene eluate as calcd from *A* at 386 nm max. Conc'n of 1  $\mu\text{g}$  benzo[a]pyrene/mL isooctane gives *A* of 0.12/cm path length at 386 nm max. (Reading in hexadecane results in bathochromic shift of max.)

(j) *Sodium sulfate*.—Anhyd., granular.

(k) *Silica gel*.—Activated (available from Fisher Scientific Co.).

(l) *Desiccant*.—Grade 42, 6–16 mesh (No. S-160). (2) *Adsorbent*.—Grade 12, 28–200 mesh (No. S-157).

(l) *Polycyclic aromatic hydrocarbons*.—Prep. sep. std solns contg 0.5 and 1.0  $\mu\text{g}$  hydrocarbon/mL isooctane. Check purity by TLC, using cellulose and cellulose acetate plates. No fluorescent impurities should be observed after chromatgy of 2–3  $\mu\text{g}$  hydrocarbon stds. If impurities are noted, purify by recrystn from benzene.

To prep. std curve for benzo[a]pyrene and other polycyclic hydrocarbon compds (e.g., benzo[e]pyrene, benzo[a]anthracene, benzo[ghi]perylene, etc.), transfer 1 mL hexadecane to 2 sep. 50 mL erlenmeyers and add 1 mL std soln contg 0.5  $\mu\text{g}$  std/mL to 1 flask and 1 mL std soln contg 1.0  $\mu\text{g}$  std/mL to other flask. Place flasks on steam bath and evap. under N to 1 mL hexadecane. For benzo[a]pyrene in hexadecane, observed max. are 255, 267, 285, 297, 363, 382, and 386 nm. *A* of 1  $\mu\text{g}$  benzo[a]pyrene/mL hexadecane is 0.12/cm path length at 386 nm (major max. in 350–400 nm region), using isooctane as ref.

(m) *Cellulose*.—Purified (Brinkmann Instruments, Inc., No. MN 300-HR; 66 00 110-5).

(n) *N,N*-Dimethylformamide (DMF).—Redistil before use.

## 21.005

### Extraction

Grind sample in meat grinder. Place 100 g in 1 L boiling flask and add 400 mL alcohol, 15 g KOH (10 g for cheese), and boiling chips. Insert Friedrich condenser and reflux 2 hr at rapid rate. (To prevent foaming, gradually increase heat to rapid reflux rate only after refluxing at relatively slow rate ca 5–10 min.)

## 21.006

### Purification

Remove condenser and transfer material while warm to 2 L separator. Wash flask twice with 125 mL  $\text{H}_2\text{O}$  and then twice with 100 mL alcohol and transfer washes to separator. Wash flask with 150 mL isooctane and pour into separator. Shake separator 3 min. Let layers sep. and drain lower layer into second 2 L separator. Let residual solids in first separator settle addnl min and carefully drain completely into second separator.

Repeat extn with 100 mL isooctane. Let sep., drain aq. layer and residual solids as before into third separator, and again ext with 100 mL isooctane. Drain aq. layer, let solids settle, and carefully remove. Discard aq. layer and solids. Wash each isooctane ext 4 times with 250 mL warm (ca 50°)  $\text{H}_2\text{O}$  by gentle swirling. (Avoid vigorous shaking; it may cause emulsions.) Discard aq. layer after each wash.

Pour 60 g treated and tested Florisil into chromatgc tube, with gentle tapping to settle contents. Place 50 g anhyd.  $\text{Na}_2\text{SO}_4$  on top of adsorbent, tapping to level surface. Prewet column with ca 75 mL isooctane, let drain by gravity, and discard eluate. Place 1 L evapn flask under column. Pass isooctane ext in first separator thru column. Let column drain by gravity. Wash first separator with ext contained in second separator and filter thru column by gravity. Wash second and first separators successively with ext in third separator, filter thru column, and again let drain. Wash third, second, and first separators in that order with 50 mL isooctane and pass wash thru column as before. Pass 125 mL benzene thru column into 1 L evapn flask. Let column drain completely. (If only benzo[a]pyrene is desired, discard all isooctane eluates and collect benzene eluate in 250 mL evapn flask.)

Add 2 mL hexadecane to eluate. Fit tube assembly into evapn flask and evap. solv. under N on steam bath as in purity test, 21.004, but evap. only to 2 mL residual hexadecane (loose Al foil jacket around flask speeds evapn). To ensure complete removal of benzene, add 10 mL isooctane, re-evap., and repeat once.

Quant. transfer the 2 mL hexadecane conc. to 500 mL separator, using total of 198 mL isooctane. Wash soln twice with 100 mL portions  $\text{H}_3\text{PO}_4$ , shaking 1 min each time. After each wash, let layers sep. (ca 10 min) and discard lower (acid) layer. After draining acid in final wash, swirl separator and let stand few min. Carefully drain any residual acid which settles out. Add 50 mL DMSO, pre-equilibrated with isooctane, and shake 2 min. Set up three 125 mL separators contg 25 mL isooctane pre-equilibrated with DMSO. After sepn of phases in 500 mL separator, drain lower (DMSO) layer into first 125 mL separator, and wash in tandem with isooctane in the three 125 mL separators, shaking each wash 1 min. Repeat extn with 2 addnl 50 mL portions DMSO, washing each ext in tandem thru same 3 portions isooctane.

Collect successive DMSO exts (150 mL total) in 1 L separator contg 300 mL  $\text{H}_2\text{O}$  and 50 mL isooctane. Let mixt. cool few min after addn of last ext, as some heat of diln is generated. Shake vigorously 2 min and let sep. Drain lower aq. phase into second 1 L separator, and repeat extn with 50 mL isooctane. Drain and discard aq. phase. Wash each 50 mL ext twice with 75 mL portions  $\text{H}_2\text{O}$ , shaking each wash ca 15 sec. Let sep. and discard aq. layer after each wash. Filter isooctane ext in first separator thru anhyd.  $\text{Na}_2\text{SO}_4$  (ca 35 g in 30 mL coarse fritted glass funnel or in 65 mL funnel with glass wool plug, and previously washed with isooctane) into 250 mL evapn flask. Rinse first separator with ext from second separator, and pass thru filter. Wash second and first separators successively in tandem with two 25 mL portions isooctane and pass individual portions thru filter. Evap. combined filtrate on steam bath under N as before to ca 10 mL. Quant. transfer soln with benzene to 50 mL g-s erlenmeyer and conc. on steam bath under N to  $\leq 0.5$  mL. (Do not evap. to dryness, since prolonged heating of polycyclic hydrocarbons in dry state will cause losses.) Reserve concd soln for TLC.

## 21.007

### Thin Layer Chromatography

To det. individual polycyclic aromatic hydrocarbons, use cellulose reverse phase technic in conjunction with cellulose

acetate multiphase technic. To det. only benzo[a]pyrene, apply conc. directly to cellulose acetate plate.

Place 20 g cellulose, (m), and 100 mL H<sub>2</sub>O in high-speed blender and homogenize 3 min at rapid speed. With thin layer applicator, apply adsorbent to five 20 × 20 cm plates at thickness of 500 μm. Let plates air dry completely. Wash plates before use in chromatgc tank by allowing mobile solv., isooctane, to migrate to top of plate in same direction as in development of chromatogram and 90° angle to application of adsorbent. Remove plate and let excess isooctane evap. Scrape off 1 cm band across top of plate to remove interfering background material which has migrated during wash. Store plates in desiccator until needed.

Pour 50 mL mobile solv., isooctane, in developing tank and equilibrate ≥30 min. In partially darkened room, apply entire benzene ext conc. to plate with micropipet or 50 μL syringe in streak ca 0.5 cm wide, 10 cm long, 2 cm from bottom of plate. (For complete seps it is essential to maintain narrow band in application of conc. This is best achieved by applying conc. in 50 μL increments and letting solv. evap. after each application without prolonged drying.) Wash sides of flask with three 0.2 mL portions benzene from graduated pipet and transfer solv. from each wash to plate as before. Complete application of conc. with 3 washings in ca 10 min. To aid identification, spot mixt. of std solns of polycyclic hydrocarbons adjacent to unknown.

Invert plate 180° and wet it to within 0.5 cm of starting line by immersion in dipping tank contg immobile solv., DMF-ether

(20+80). Remove plate and let excess immobile solv. drain ca 15–20 sec. Return plate to original position (starting line on bottom), place in tank satd with isooctane, and develop in dark until mobile solv. reaches top of plate (ca 1 hr at 25°).

When development is complete, remove plate from tank and observe positions of polycyclic compds on *wet* plate under both longwave and shortwave UV light. Outline fluorescent bands.

Remove plate from cabinet, scrape off excess adsorbent around bands with spatula, and discard. Transfer each outlined band of adsorbent to sep. 125 mL beakers, and immediately elute polycyclic hydrocarbon by extg with 5–10 mL portions hot MeOH until fluorescence under UV light can no longer be seen in last portion of solv. Swirl flask repeatedly during extn and successively decant individual exts thru 30 mL pressure filter, 21.003(f), under N into 50 mL flask. (Pulverize collected adsorbent in beaker with spatula prior to hot MeOH extn to aid complete recovery of compds. Three or 4 extns are usually enough to remove compds from adsorbent.) After extn, evap. each ext to ca 0.5 mL, add 5 mL benzene, and re-evap. to ca 0.2–0.3 mL. Do *not* evap. to dryness. Reserve concs for TLC on cellulose acetate plates.

Place 50 g cellulose acetate and 275 mL alcohol in high-speed blender and homogenize 3 min at rapid speed. (Ten plates can be prep'd with this amt slurry.) With thin layer applicator, apply adsorbent to plates (10 × 20 cm) at thickness of 1000 μm. Let plates air dry 4 hr and store in desiccator over silica gel, (k)(1), until needed.

Pour 50 mL mobile solv. (alcohol-toluene-H<sub>2</sub>O, 17+4+4) in

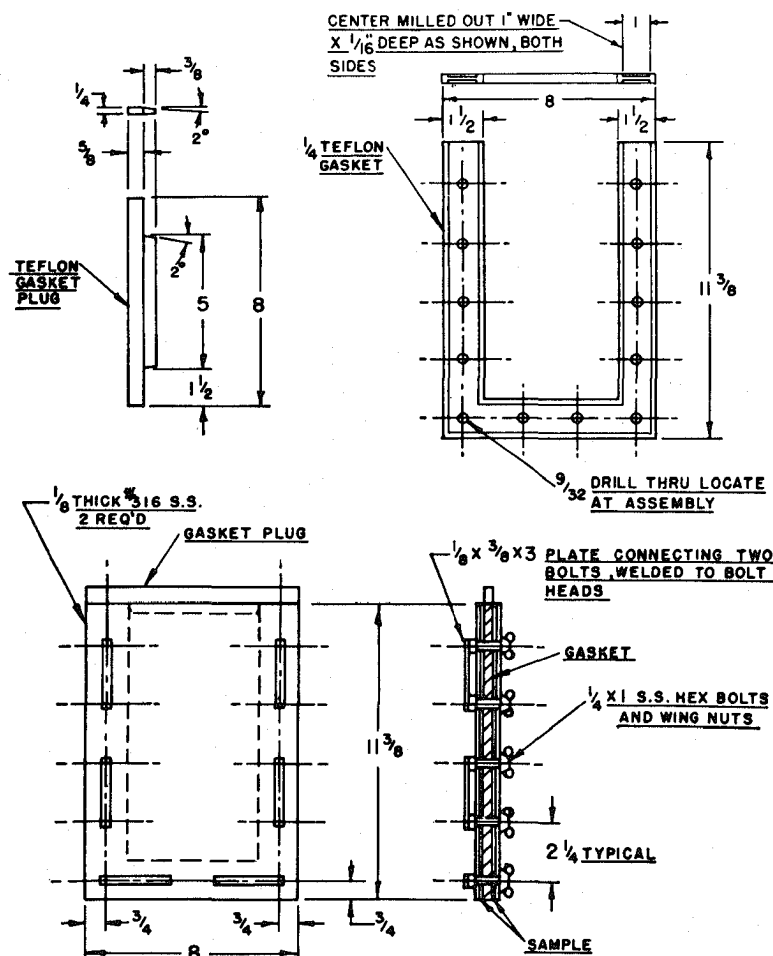

FIG. 21:01—Test cell

developing tank and equilibrate  $\geq 1$  hr. In partially darkened room, apply exts obtained from cellulose plate in streak as above. Wash sides of flask with four 0.2 mL portions benzene from graduated pipet and transfer solv. from each wash to plate as before. Complete transfer of each ext in ca 10 min. After solv. evaps, place plate in tank and let chromatogram develop in dark until solv. front reaches top of plate (ca 1.5 hr at 25°).

When development is complete, remove plate from tank and observe positions on wet plate under both longwave and shortwave UV light in Chromato-Vue cabinet. Outline fluorescent bands.

## 21.008

**Ultraviolet Spectrophotometry**

Remove plate from cabinet, scrape off adsorbent around bands with spatula, and discard. Transfer each outlined band of adsorbent to sep. 50 mL pressure filters; elute hydrocarbons from adsorbent by extg with 5–10 mL portions hot MeOH, and filter thru 30 mL pressure filter, 21.003(f), under N into 50 mL flask. Repeat this operation 3 addnl times with 5–10 mL portions hot MeOH. After extn, add 1 mL hexadecane to combined ext and evap. MeOH on steam bath under N. Remove any residual MeOH in flask by adding two 5 mL portions isooctane and re-evapg under N.

Carefully transfer 1.0 mL hexadecane soln to 1 cm path length cell (total capacity 1.5 mL) and record UV spectrum in 250–400 nm range against isooctane in ref. cell. Compare any max. observed with those in spectra obtained for std solns of polycyclic aromatic hydrocarbons. Est. amt of identified hydrocarbons by using baseline technic.

## 21.009

**Spectrophotofluorometry**

Carefully transfer soln from spectrophtr cell into fluorometer cell and record excitation and emission spectra. Compare fluorescence spectra obtained with those of 0.5 and 1.0  $\mu\text{g/mL}$  std solns of compds and calc. amt present.

**Exposing Flexible Barrier Materials for Extraction****ASTM-AOAC Method (2)—Official Final Action**

## 21.010

**Principle**

Method provides std liq. extn method for flexible barrier materials, singly, coated, or combined, including extns thru flexible barrier materials of surface coating ingredients, by food-simulating solvs. Specimens of flexible barrier materials are exposed to extg liqs in test cell and amt of nonvolatile extractives remaining after exposure is measured.

## 21.011

**Apparatus**

(a) *Test cell*.—See Fig. 21.01. Consists of two  $8 \times 11\frac{3}{4} \times \frac{1}{8}$ " No. 316 stainless steel plates, degreased; one  $\frac{1}{4} \times 1\frac{1}{2}$ " U-shaped virgin TFE-fluorocarbon (Teflon) gasket, grooved on both sides as shown; twelve  $\frac{1}{4} \times 1$ " stainless steel bolts with wing nuts; one  $\frac{1}{4} \times 1 \times 8$ " TFE-fluorocarbon gasket plug tapered to provide tight fit. (Available from Scientific Products, No. E6200.) To prep. app. for use, wash plates and gaskets in aq. detergent soln. Rinse with  $\text{H}_2\text{O}$  and dry at 100°. Wash with *n*-heptane and redistd acetone. Immerse new gaskets in *n*-heptane overnight. Rinse gaskets with fresh *n*-heptane and dry at 100°.

(b) *Oven rack*.—See Fig. 21.02. To hold extn test cells.

(c) *Hot air oven*.—With safety provisions for flammable solvs. Vac. oven or autoclave is suitable.

## 21.012

**Reagents**

Use solvs (usually  $\text{H}_2\text{O}$ , dil. alcohol, and *n*-heptane) specified in regulations (Code of Federal Regulations, Title 21, Sec. 175.300(d) Table 2; 176.170(c) Table 2). Solv. for blanks and detn should be from same container.

## 21.013

**Preparation of Cells**

Select samples of flexible barrier material and protect from exposure to liqs or contamination by migration from contact

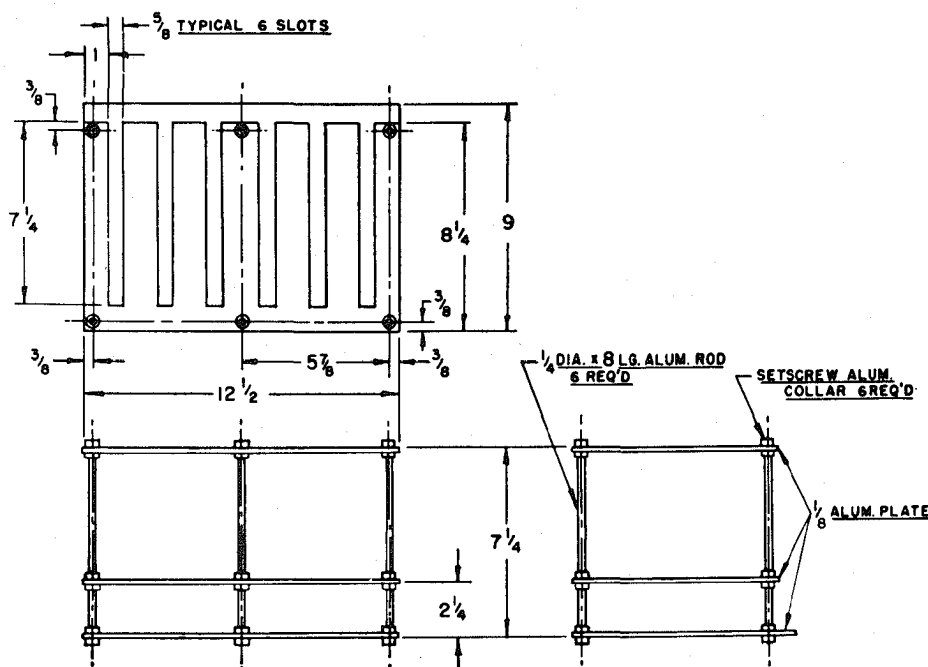

FIG. 21.02—Oven rack

with other materials, and from wrinkling or abrasion. Samples shall equal or exceed cell dimensions ( $8 \times 11\frac{3}{4}$ ").

Place 1 stainless steel plate of cell on flat surface with bolts protruding up thru holes in plate. Place prepunched specimen (side to contact liq. up) on plate with 1 edge aligned with bottom of plate, 2 edges aligned with sides of plate, and bolts passing thru prepunched holes. Place gasket on specimen with outer edges of gasket aligned with cell bottom and sides. If desired, place second prepunched specimen (side to contact liq. down) on top of gasket. If only 1 sheet is used for test, place inert barrier sheet such as Teflon or electrolytically cleaned Sn foil in place of second sheet. Place second stainless steel plate on top of assembly. Place wing nuts on bolts and tighten.

Preheat assembly (including TFE-fluorocarbon gasket plug) to test temp. and retighten nuts so that assembly is liq.-tight.

#### 21.014

#### Determination

Place measured vol. of extg liq., preheated to test temp., into assembly. Use vol. of liq. such that top of liq. is 0.5" below top of specimen. In no case should vol. of extg liq. be >200 mL. Insert gasket plug in top of cell. Expose cell in rack in oven to conditions of time and temp. specified by regulations. If vac. oven is used, operate it at atm. pressure. Align cells in rack in oven parallel with air flow.

After exposure, remove cell from rack, remove gasket plug, and immediately pour out extg liq. into graduate. (If solids flake from specimen and it is desired to det. only sol. materials, filter thru fritted glass filter from cell into graduate.) If vol. of extg liq. is <90% of original vol., investigate cause.

Det. total nonvolatile extractives by evapg total vol. extg liq. to apparent dryness in weighed Pt evapg dish on steam bath. Dry in oven 30 min at 100°. Cool 30 min in desiccator and weigh.

Perform  $\geq 2$  blank detns with 200 mL extg liq. each and glassware that will be used in detn. Preclean glassware with chromic acid soln followed by H<sub>2</sub>O rinse. Place equal vol. extg liq. into each of blank-receiving containers. If filter is used on extg liq. from exposed samples, include contact of solv. of blank with filter. Wt blank must be <2.0 mg/200 mL and <30% of wt extractives.

#### 21.015

#### Calculation

With 2 sheets in cell, ratio of exposure area to vol. extg liq. used to fill cell is 2 mL/sq in. Calc. mg extractives/sq in. exposed sample = (mg extractives - mg blank)/sq in. exposed sample.

#### Extractives from Rubber Articles (3)—Official Final Action

#### 21.016

#### Apparatus

(a) *Extraction flasks*.—500 mL wide-mouth erlenmeyer, neck id ca 35 mm (500 mL Pyrex g-s  $\frac{3}{8}$  40/50 flasks are satisfactory).

(b) *Reflux condenser*.—Block Sn coil (Sargent-Welch Scientific Co., No. S-31555, or equiv.).

(c) *Measuring tools*.—Micrometer and precision ruler.

(d) *Punch*.—1-, 2-, or 3-hole conventional paper punch with punch of  $\geq \frac{3}{8}$ " diam.

#### 21.017

#### Preparation of Sample

Punch out disks of ca  $\frac{3}{8}$ " diam. from test material. Wash disks by hand in dil. soap soln at ca 40°; rinse with 40° H<sub>2</sub>O and then distd H<sub>2</sub>O and blot dry with paper towel.

#### 21.018

#### Measurement of Surface Area

Measure thickness of 20 disks with micrometer ( $\pm 0.001$ ") and calc. av. thickness. Measure diam. to nearest  $\frac{1}{32}$ " and verify measurements of  $\geq 10$  disks. If deviations of  $\pm \frac{1}{32}$ " are noted, then det. av. diams for  $\geq 20$  disks. Calc. total surface area for disks tested as follows:

$$\text{Total surface area} = N[2 \times (22/7) \times (d^2/4) + (22/7) \times d \times t],$$

where  $N$  = no. of disks,  $d$  = av. diam. in in., and  $t$  = av. thickness in in.

#### 21.019

#### Determination

(Caution: See 51.011, 51.039, and 51.061.)

Place counted number of disks into extn flask; add few SiC chips and measured vol. of solv. ( $n$ -hexane or H<sub>2</sub>O). (Total surface area of disks should be 10–20 sq in. and vol. of solv., in mL, is 20 times number of sq in. surface area.) Mark level of solv. and add fresh solv. if losses occur during extn. Attach thoroly cleaned and acetone-rinsed condenser to flask and reflux 7 hr on hot plate. Adjust temp. of hot plate to give boiling rate that keeps disks in motion without excessive foaming. If disks tend to stick together, agitate them 5–6 times during extn. Rinse condenser with small amt solv. and remove flask from hot plate. Decant ext into beaker and rinse flask and disks with three small portions hot solv. Discard disks.

Weigh 125 mL fat flask, or 100 mL beaker, contg few SiC chips, after heating 1 hr at 100° and cooling 1 hr in desiccator. Transfer ext and rinses, in 50–80 mL portions, to tared flask or beaker. For blank, transfer vol. solv. equal to ext plus rinses to similar weighed beaker or flask. Evap. each portion to ca 20 mL before adding more ext. Swirl flask or beaker frequently while heating until soln begins to boil. Hexane ext can be evapd to dryness entirely on steam bath with stream of filtered air; H<sub>2</sub>O ext can be concd to ca 10 mL on hot plate before evapg to dryness on steam bath.

Wipe outside of flask with damp paper towel and place flask on its side in oven. Dry hexane ext at 70° and H<sub>2</sub>O ext at 105° 1 hr. Cool in desiccator 1 hr and weigh on anal. balance. Subtract wt of solv. blank from wt of residue. Divide corrected wt of residue in mg by total surface area of test disks and report as mg/sq in.

## 22. Fruits and Fruit Products

### 22.001 Sampling (7)—Procedure

(a) *Boxed dried fruit*.—Remove cover, bottom, or one side of box, as convenient. Remove block comprising  $\frac{1}{4}$  of contents of box taken from one corner as follows: With sharp knife make vertical cut midway between *ends* of box to center of top surface, extending cut half way to bottom. Make another vertical cut midway between *sides* of box, extending half way to bottom, and continue it until it meets first cut. Remove all fruit included in angle formed by the 2 cuts. Working rapidly, break up lumps, mix thoroly, and take enough sample to fill qt (1 L) Mason jar, replacing remainder in box. Seal jar and send to laboratory. Sample enough boxes from different parts of pile to constitute at least sq root of lot.

(b) *Frozen pack fruit in barrels*.—Use stainless steel or corrosion-resistant tube ca 3 cm (1.25") diam. and 90 cm (36") long, one end serrated and set to run freely, other end with removable cap and arrangement for use of elec. motor in drilling. To aid in removal of core samples use wooden ram smaller in diam. but longer than tube.

Remove bottom of barrel and take 3 cores evenly spaced around its circumference near chime, parallel to and thru full length of barrel. Take fourth core at approx. center of barrel.

(c) *Frozen pack fruit in small containers (30–50 lb)*.—Use modified corrosion-resistant auger 2.5–3.0 cm (1–1.5") diam. and 50 cm (19") long that can be operated by elec. motor. (Auger should have no lead screw or cutters and angle of face should not be flat but 170–175°.) Collect borings in corrosion-resistant sampling can ca 15 cm (6") diam. and 10 cm (4") high, open at one end, with outlet at other end ca 2.5 cm (1") long and of diam. slightly larger than that of auger. Place sampling can on surface of frozen fruit and operate auger thru small opening at bottom. Take 3 vertical cores evenly spaced around circumference and ca 1.3 cm (0.5") from edge of container and take 1 core at or near center. Remove both sampling can and auger simultaneously to prevent borings from falling thru delivery outlet.

### 22.002 Net Contents of Frozen Fruits—Procedure

See 32.050–32.051.

#### Fill of Container of Frozen Fruits (2)—Official First Action

### 22.003

#### Apparatus

(a) *Overflow can*.—With device for lowering frozen fruit into liq. and for removing it, Fig. 22:01. Can is ca 20 cm (8") diam. and ca 23 cm (9") high with overflow spout of 0.5 cm ( $\frac{3}{16}$ " id) ( $\frac{1}{4}$ " od) Cu tubing. Solder tubing to opening on side of can ca 1.3 cm (0.5") from bottom and bend upward parallel to side of can to ca 5 cm (2") below top where it is bent away and downward to form inverted U. Form spout by cutting tubing on outer side of U where it makes ca 45° angle with can, making cut parallel to bottom of can. Opening of spout is ca 0.3 cm ( $\frac{1}{16}$ ") below lower surface of U-bend. Bend end of spout up or down until overflow, caused by adding excess of liq. to can, will end abruptly. (Proper adjustment of tube and addn of enough liq. will secure this effect.) Lowering device consists of 1.3 cm (0.5") metal frame 14.6 cm (5.75") square contg 1.3 cm (0.5") mesh screening attached on one side to perpendicular handle 30 cm (12") long bent outward at top.

(b) *Plastic bags*.—Polyethylene; pliable at 0°F; capable of holding vac.; ca 8 × 10" when flat.

(c) *Freezer or cold room*.—At or near 0°F.

(d) *Refined light mineral oil such as odorless kerosene*.

### 22.004

#### Determination

Transfer frozen sample from container and inner wrapper, if any, to plastic bag. Remove excess air from bag by inserting glass tube attached to vac. line. Twist bag top to close, hold twist with pinch clamp, and trim off loose end. Pretest bags to be certain they will not leak.

Place overflow can in freezing compartment and fill can, in which lifting device is inserted, with light mineral oil at temp. of freezing compartment (ca 0°F). Add enough excess mineral oil (ca 300 mL) to produce siphon effect in overflow, collecting overflow in beaker. Place empty, calibrated graduate under overflow tube and immerse frozen fruit sample completely in the mineral oil, using lifting device. Record vol. of overflow in graduate to nearest mL. Correct this vol. for displacement of empty plastic bag and pinch clamp (ca 7 mL) to obtain net displacement of frozen fruit. Redet. displacement of sample to check reproducibility of operation.

For packages with square corners, calc. H<sub>2</sub>O capacity of outer container by multiplying inside length, width, and ht in cm. For packages with curved edges or irregular shape, det. H<sub>2</sub>O capacity as follows: Place empty container in beaker or pan contg enough H<sub>2</sub>O to reach to within 1 cm of top of container when it is resting on bottom of beaker or pan. Note that no air is trapped by bottom of container. Add H<sub>2</sub>O from calibrated 500 mL buret to fill container to capacity, or to measured headspace if indented top has been removed. Read H<sub>2</sub>O capacity directly from buret.

Det. % fill of container by dividing net displacement of frozen fruit by H<sub>2</sub>O capacity of outer container and multiply by 100.

### 22.005 Drained Weight of Frozen Fruits (3)

#### Official First Action

After obtaining gross wts, immerse packages in H<sub>2</sub>O agitated and maintained at 20±1°. (If packages are not H<sub>2</sub>O-tight, place in suitable plastic bag, remove excess air by use of vac., and tie off.) Avoid agitation of packages during thawing by using clamps

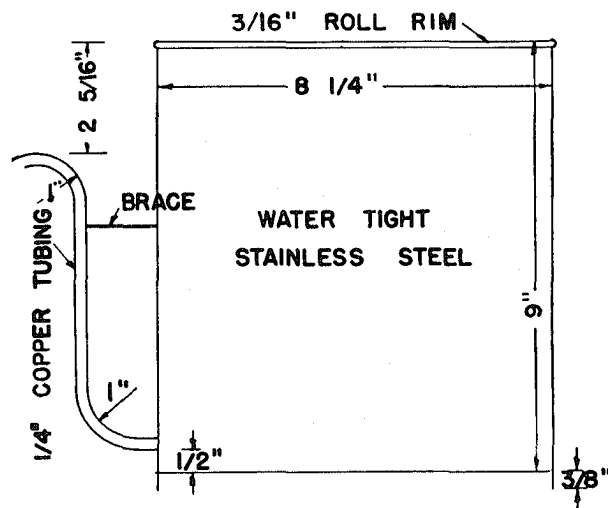

FIG. 22:01—Apparatus for determining volume of frozen fruits by displacement

or weights if necessary. When center of packages reaches bath temp. as detd by preliminary experiments (ca 2–3 hr for 10.5–16 oz (300–450 g) containers), remove from bath, blot off adhering H<sub>2</sub>O, and open with min. agitation.

Tare No. 8 sieve with light-wt drip pan. Use 8" (20 cm) diam. sieve if container holds ≤3 lb (1.4 kg), 12" (30 cm) if more. With screen tilted and supported for drainage, distribute contents of package evenly over screen in one sweeping motion. After 2 min from time drainage begins, transfer sieve with fruit to drip pan and weigh. Obtain net wt of packages by subtracting wt empty containers from their gross wts.

#### 22.006 Thawing Frozen Fruit (4)—Procedure

(FAO/WHO Method)

Use entire package or intact sample unit; for bulk products, use 1–2 kg representative sample. Apply 1 of following technics appropriate to product, e.g., for corn, use air thawing or indirect contact to avoid leaching solids. Use method which will provide most rapid thawing without altering or degrading product characteristics. Proceed until product is sufficiently free from ice crystals to permit easy sepn and handling of individual units. Light-colored fruits (apricots, peaches) and red cherries oxidize readily and should be examined for color while some ice crystals remain in product.

(a) *Air thawing*.—Thaw in unopened container at room temp. To hasten thawing, apply forced air from fan and sep. packages.

(b) *Indirect water thawing*.—Place sample in plastic bag capable of being sealed H<sub>2</sub>O-tight. Remove most of air, seal, and apply wts or clamps if necessary to avoid agitation of sample. Immerse in stationary or flowing H<sub>2</sub>O at ≤30°.

#### 22.007 Approximate Fruit Content of Fruit-Sugar Mixtures (5)—Procedure

Let sample thaw and come to room temp. in original container. Mix sample thoroly in high-speed blender. Filter portion of sample thru strong lens paper or other suitable medium. Det. refractometer reading, **31.011**, correct to 20°, and report as % sol. solids (sucrose). Calc. % fruit, *X*, from equation:

$$X = (100 - M) 100 / (100 - F),$$

where *M* is sol. solids (as sucrose) of fruit-sugar mixt. and *F* is sol. solids of fruit ingredient in mixt. if known; otherwise use av. sol. solids of authentic fruits (JAOAC **21**, 502(1938); **47**, 1068(1964); **48**, 523(1965); **51**, 1203(1968); **52**, 643, 1047, 1150(1969); **55**, 200, 1104(1972).

#### 22.008 Preparation of Sample—Procedure

Transfer samples received in open packages (*i.e.*, not sterile) without delay to g-s containers and keep in cool place. To avoid effects of fermentation, make prompt detns of alcohol, total and volatile acids, solids, and sugars, particularly in case of fruit juices and fresh fruits. (Portions for detn of sucrose and reducing sugars may be weighed and kept several days without fermenting if the slight excess of neut. Pb(OAc)<sub>2</sub> soln required in detn is added. *Note*: Pb(OAc)<sub>2</sub> is toxic. Label samples to show its addn.) Prep. various products for analysis as follows:

(a) *Juices*.—Mix thoroly by shaking to ensure uniform sample, and filter thru absorbent cotton or rapid paper. Prep. fresh juices by pressing well pulped fruit and filtering. Express juice of citrus fruits by one of common devices used for squeezing oranges or lemons, and filter.

(b) *Jellies and sirups*.—Mix thoroly to ensure uniform sample. Prep. soln by weighing 300 g thoroly mixed sample into 2 L flask and dissolve in H<sub>2</sub>O, heating on steam bath if necessary. Apply as little heat as possible to minimize inversion of sucrose.

Cool, dil. to vol., mix thoroly by shaking, and use aliquots for the various detns. If insol. material is present, mix thoroly and filter before taking aliquots.

(c) *Fresh fruits, dried fruits, preserves, jams, and marmalades*.—Pulp by passing thru food chopper, or by use of soil dispersion mixer, Hobart mixer, or other suitable mech. mixing app., or by grinding in large mortar, and mixing thoroly, completing operation as quickly as possible to avoid loss of moisture. With dried fruits, pass sample thru food chopper 3 times, mixing thoroly after each grinding. Set burrs or blades of food chopper as close as possible without crushing seeds. Grind entire contents of No. 10 or smaller container. Mix contents of larger containers thoroly by stirring and remove portion for grinding. With stone fruits, remove pits and det. their proportion in weighed sample.

Prep. soln by weighing into 1.5–2 L beaker 300 g fresh fruit, or equiv. of dried fruit, preserves, jams, and marmalades, well pulped and mixed in blender or other suitable type of mech. grinder; add ca 800 mL H<sub>2</sub>O; and boil 1 hr, replacing at intervals H<sub>2</sub>O lost by evapn. Transfer to 2 L vol. flask, cool, dil. to vol., and filter. With unsweetened fruit, ashing is facilitated by addn of sugar before boiling; therefore weigh 150 g fruit, add 150 g sugar and 800 mL H<sub>2</sub>O, and proceed as above.

(d) *Canned fruits*.—See **32.001–32.002**. Carefully invert by hand all fruits having cups or cavities if they fall on sieve with cups or cavities up. Cups or cavities in soft products may be drained by tilting sieve, but no other handling of these products while draining is permissible. Examination of sirup in which fruits are preserved is often enough. Sep. liquor by draining, **32.002**, and treat as in (a).

#### Apparent Viscosity (Consistency) (6)—Official Final Action

(Applicable to fruit nectars and fruit juice products)

##### 22.009

##### Apparatus

*Capillary viscometer*.—See Fig. **22.02**. *A*, Lucite tube chamber; *B*, inner tube, ground 120° included angle; *C*, Lucite plug, 60° included angle; *D* Tygon packing gland, turned 60° included angle (both ends); *E*, brass outer tube, ground 60° for packing gland nut; *F*, brass tube, chrome plated; *G*, inner tube, precision Pyrex glass, id 3±0.01 mm; *H*, Tygon sleeve. Scribe calibration line around outside of reservoir at level reached by H<sub>2</sub>O in 13 sec under conditions specified in **22.010**. (Available from S. M. I. Inc., 800 University Ave, Berkeley, CA 94710, Cat. No. 8500.)

##### 22.010

##### Calibration

Add H<sub>2</sub>O to tube at 24±2° and establish steady flow. Stop flow by placing finger over end of capillary tube. Completely fill tube to overflow point and level off with spatula or by sighting across top of tube. Remove finger from tube and immediately begin timing. Time required for top of meniscus to reach calibration line must be 13.0±0.2 sec.

##### 22.011

##### Determination

Clean and dry app. and maintain at 24±0.5° during detn. Adjust sample to 24±0.5° and mix thoroly without incorporating air bubbles. Add sample to tube and let flow until steady flow is obtained. Place finger over end of capillary tube to stop flow. Fill tube almost full and check for air bubbles; if air bubbles occur, remove by gently stirring with stirring rod or thermometer (check temp. at this point). Fill to overflow point and level off as in **22.010**. Remove finger from tube and immediately begin timing. Record time to nearest 0.1 sec for top of meniscus to reach calibration line.

Obtain ≥2 readings on each sample, mixing sample before

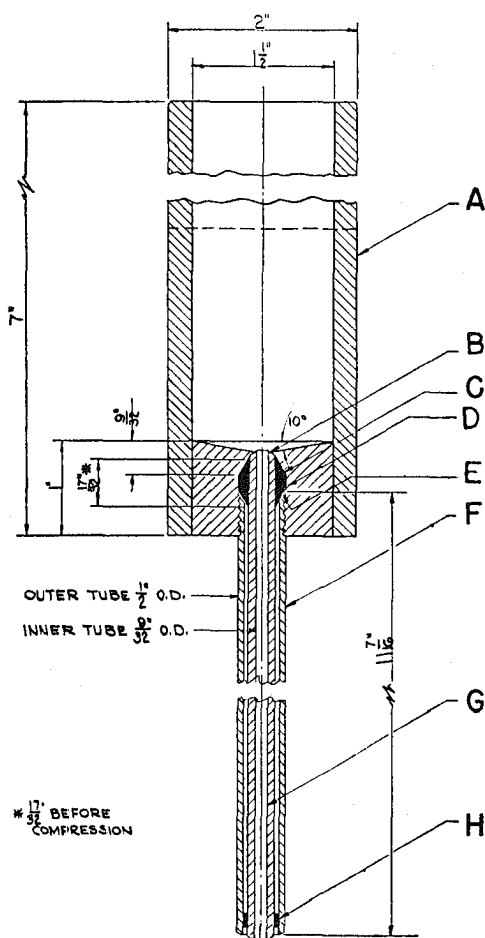

FIG. 22:02—Capillary viscometer

each detn. Rinse viscometer with H<sub>2</sub>O between each reading of viscous samples (>30 sec flow time). (Do not let product dry in app. or let app. become greasy or develop air leak at packing seal of capillary tube.) Remove H<sub>2</sub>O in capillary tube by letting sample flow thru before making detn. Check calibration at frequent intervals.

#### 22.012 Alcohol—Official Final Action

Det. alcohol in 50 g original material as in 11.005.

#### 22.013 Moisture in Dried Fruits (7)—Official Final Action

Spread 5–10 g prepd sample, 22.008(c), as evenly as possible over bottom of metal dish ca 8.5 cm diam. provided with tight-fit cover, weigh, and dry 6 hr at  $70 \pm 1^\circ$  under pressure  $\leq 100$  mm Hg (13.3 kPa). (Metal dish must be in direct contact with metal shelf of oven.) During drying, admit to oven slow current of air (ca 2 bubbles/sec) dried by passing thru H<sub>2</sub>SO<sub>4</sub>. Replace cover, cool dish in desiccator, and weigh. Disregard any temporary drop in oven temp. during early part of drying period owing to rapid evapn of H<sub>2</sub>O.

With raisins, and other fruit rich in sugar, use ca 5 g sample and dry and weigh in dish with ca 2 g finely divided asbestos. (Caution: See 51.086.) Moisten with hot H<sub>2</sub>O, mix sample and asbestos thoroly, evap. barely to dryness on steam bath, and complete drying as above.

Duplicate detns should agree within 0.2%.

#### Moisture in Prunes and Raisins—Official First Action

##### Alternative Method (8)

#### 22.014

##### Apparatus

Dried fruit moisture tester meter.—Type A series (DFA of California, PO Box 270A, Santa Clara, CA 95052); see Fig. 22:03 for elec. circuit.

	R12	10K	±5	(wire-wound)

**22.015****Determination**

Grind sample 3 times thru food chopper, using cutter with 16 teeth. If testing hot fruit from processor, cool fruit as follows: Mix ca 60 g chopped solid CO<sub>2</sub> with fruit and then grind mixt. 3 times before taking moisture reading. Pack ground sample into Bakelite cylinder with fingers, making certain that it is packed tightly around bottom electrode. Fill cylinder completely with tightly packed sample, and level.

Lower top electrode and press it into sample until top electrode lever is against stop. Insert thermometer into ground sample until thermometer bulb is ca halfway between electrodes.

Select correct table for type and condition of fruit being tested (Table 22:01: natural or low moisture, tap 6 setting; Table 22:02: processed, tap 3 setting). Set switch (S2) to number given on table selected.

Plug tester into 110 v ac outlet and put switch to "on". (Red light indicates current.) Keep push button down and turn dial so that meter needle moves toward 0. Adjust dial so that needle is at its lowest, or turning, point. After making fine adjustment of dial to meter 0 or turning point, read dial and then read thermometer.

**22.016****Use of Tables**

Choose temp. column of appropriate table nearest to sample

temp. Read down this column to figure closest to dial reading, then read across to "% Moisture" column.

**22.017****Example**

Examination of processed raisin sample gave following data: dial setting 76 and temp. 74°F, on tap 3. Looking down 74° column (Table 22:02), obtain 75.2 at 18.5% moisture and 78.4 at 19.0% moisture. Since reading is nearer to 18.5 than 19.0%, report sample as contg 18.5% moisture, or interpolate.

**Total Solids—Official Final Action****22.018 Insoluble Matter Present**

*Fresh and canned fruits, jams, marmalades, and preserves.*—Accurately weigh, into large flat-bottom dish, 20 g pulped fresh fruit, or wt of fruit products that will give ≤3–4 g dry material. If necessary to secure thin layer of material, add few mL H<sub>2</sub>O and mix thoroly. Dry at 70° under pressure ≤100 mm Hg (13.3 kPa) until consecutive weighings made at 2 hr intervals vary ≤3 mg.

**22.019 Insoluble Matter Absent**

*Fruit juices, jellies, and sirups.*—Proceed as in 31.007, 31.008, 31.009, 31.010, or 31.011, using sample prepd as in 22.008(a) or (b).

**Water-Insoluble Solids (9)—Official First Action****22.020 Method I**

For use with buchner, prep. filtering medium consisting of either circular disk of absorbent cotton ca 80 mm diam., weighing ca 1.5 g, or coarse, qual. filter paper (7–15 cm diam., Whatman No. 4 or 41-H, or equiv.). For use with 60° funnel, prep. absorbent cotton circle ca 12.5 cm diam. weighing ca 2 g, or 12.5 cm filter paper. Wash filtering medium with hot H<sub>2</sub>O, and dry overnight at 100–110° in open, flat-bottom Al dish of suitable size provided with tight-fit cover. Cool closed dish and contents 1 hr in desiccator and weigh to nearest mg.

Weigh 25 or 50 g well mixed sample, **22.008(c)**, to nearest 10 mg, transfer to 400 mL beaker, dil. to ca 200 mL mark with hot H<sub>2</sub>O, mix, and boil gently 15–20 min, occasionally replacing H<sub>2</sub>O lost by evapn. Filter by gravity thru the prepd cotton or paper, and keep H<sub>2</sub>O-insol. solids from forming closely adhering mat on surface of filtering medium by frequent addns of portions of sample. Wash with ca 800 mL hot H<sub>2</sub>O, loosening H<sub>2</sub>O-insol. solids from filter with each addn. Remove excess H<sub>2</sub>O from cotton by gently squeezing it on 60° funnel, or by application of suction on buchner. Transfer to original weighing dish, and wipe off any remaining portions of H<sub>2</sub>O-insol. solids on filter or funnel with previously weighed portion of prepd filtering medium. Dry overnight at 100–110°, cool 1 hr in desiccator, and weigh.

**Method II (Rapid Method)****22.021****Apparatus**

(a) *Weighing dishes*.—Al or tinned Fe, 13 cm (5.25") diam. × 1.9 cm (0.75") high, with tight-fit cover (16 mm film holders obtainable from camera stores; Al dishes weigh ca 40 g, tinned Fe ca 85–90 g).

(b) *Rapid drying device*.—Moisture Teller, model 276, manufactured by Harry W. Dietert Co., 9330 Roselawn Ave, Detroit, MI 48204, or forced-draft drying oven set at 100°.

**22.022****Determination**

Fit 15 cm filter paper (Whatman No. 4 or 41-H, or equiv.) into 12.5 cm buchner, add half of 7 cm paper (used to wipe any insol. solids from buchner after filtering and washing sample), wash with boiling H<sub>2</sub>O, apply suction, and dry, using Moisture Teller and pan or forced-draft oven. Transfer to weighing dish, cool, and weigh, using tare consisting of weighing dish and paper. (Approx. time of drying, 5 min at 102±3°.)

Weigh 25 or 50 g well mixed sample (high-speed blender) to nearest 10 mg, transfer with hot H<sub>2</sub>O to 400 mL beaker, adjust to ca 200 mL with hot H<sub>2</sub>O, stir, and boil gently few min. Place prepd filter in buchner; attach to suction flask, but do not attach flask to suction line. Pour 50–100 mL boiling H<sub>2</sub>O on filter, and when steady flow of H<sub>2</sub>O passes thru filter, transfer sample to filter, portionwise if necessary. Wash insol. solids with boiling H<sub>2</sub>O and collect 850–900 mL filtrate. During washings, keep solids from forming tight mat on surface by portionwise addns of boiling H<sub>2</sub>O. When washing is finished, apply suction and aspirate thoroly. Transfer paper and H<sub>2</sub>O-insol. solids to Moisture Teller pan, using extra piece of weighed filter paper to complete transfer, and dry at 102±3° ca 15 min, depending on amt of H<sub>2</sub>O-insol. solids. After drying, transfer sample to weighing dish, cool in desiccator, and weigh. (Wt H<sub>2</sub>O-insol. solids/wt sample) × 100 = % H<sub>2</sub>O-insol. solids.

**22.023 Seeds in Berry Fruits (10)—Official First Action**

Prep. sample by mixing with blender, **22.008(c)**. Transfer 50±0.01 g with ca 500 mL hot H<sub>2</sub>O to blender and mix 1–2 min.

Transfer mixt. to No. 20 screen and use addnl hot H<sub>2</sub>O to transfer and wash bare seeds (hot H<sub>2</sub>O from tap is suitable). Transfer seeds on screen to Al dish, previously weighed, with tight-fit cover (readily accomplished by transferring to 7 cm Whatman No. 4 paper previously dried and weighed with the dish, in 12.5 cm buchner). Dry at 100° in forced-draft oven 30 min and weigh. To det. av. wt of one seed, count out and weigh sep. several 100-unit lots. Report av. wt of one seed in mg and number of seeds/100 g sample. After detn of H<sub>2</sub>O-insol. solids of sample, calc. and report % of total due to bare seeds and % due to nonseed H<sub>2</sub>O-insol. solids.

**Soluble Solids by Refractometer—Official First Action****22.024 Fresh and Canned Fruits, Fruit Jellies, Marmalades, and Preserves (11)**

(Insol. matter present)

Proceed as in **31.011**. % sol. solids = % solids detd by refractometer × (100 – b)/100, where b = % H<sub>2</sub>O-insol. solids.

*Note:* U.S. Federal stds for frozen fruits, canned fruits, fruit jellies, and preserves make no correction for H<sub>2</sub>O-insol. solids, invert sugar, or other substances.

**22.025 Frozen Concentrate for Lemonade (12)**

Proceed as in **22.024**. Correct values for sucrose by refractometer for acidity by adding (– 0.027 + 0.125 x) to sucrose value, where x = % anhyd. citric acid in sample as detd in **22.060** or **22.061**.

**22.026 Ash (13)—Official Final Action**

Proceed as in **31.012** or **31.013**, ashing at ≤525°, using 25 g juices, fresh fruits, or canned fruits, and 10 g jellies, sirups, preserves, jams, marmalades, or dried fruits.

If ash of H<sub>2</sub>O-sol. portion only is desired, evap. 100 mL prepd soln, **22.008(b)** or (c), to dryness on steam bath. Proceed as in **31.012** or **31.013**.

**22.027 Alkalinity of Ash—Official Final Action**

Introduce measured excess of 0.1N HCl into Pt dish contg ash obtained in **22.026**, warm on steam bath, cool, add few drops Me orange, and titr. excess acid with 0.1N NaOH. Report as alky, number of mL 0.1N acid required to neutze ash from 100 g sample, and as alky number, number of mL 1N acid required to neutze 1 g ash. Reserve soln for detn of S in ash.

**Potassium (14)—Official Final Action****22.028****Ashing of Sample**

(a) *Slow ashing*.—Ash 15–30 g sample (representing ca 15 g fruit) as in **22.026**.

★(b) *Rapid ashing*.★—See **20.019(b)**, 10th ed.

**★ Chloroplatinate Methods ★****22.029****Reagents**

(a) *Ammonium chloride soln*.—Dissolve 100 g NH<sub>4</sub>Cl in 500 mL H<sub>2</sub>O, add 5–10 g pulverized K<sub>2</sub>PtCl<sub>6</sub>, and shake at intervals 6–8 hr. Let mixt. settle overnight and filter. (Residue may be used to prep. fresh supply.)

(b) *Chloroplatinic acid soln*.—Dissolve 4.4 g H<sub>2</sub>PtCl<sub>6</sub> (contains 2.1 g Pt) in H<sub>2</sub>O and dil. to 100 mL. 1 mL of this soln ppts ca 10 mg K<sub>2</sub>O. Use ca 20% excess.

★ Surplus method—see inside front cover.

**22.030****Preparation of Ash Solution**

Wet down ash, **22.028**, with 5–10 mL  $H_2O$ , cover dish with watch glass, and acidify with slight excess of  $HCl$  (1+4) (2–3 mL).

**22.031****Determination**

(a) *Gravimetric chloroplatinate method*.—Rinse watch glass into dish and evap. ash soln to dryness on steam bath. Add 5 drops  $HCl$  (1+1) to residue. Add 5–10 mL hot  $H_2O$  and rub sides and bottom of container with policeman. Transfer ash soln to 250 mL beaker with 50–75 mL hot  $H_2O$ , add few glass beads, and heat to bp. Make distinctly alk. with  $NH_4OH$  and add enough satd  $(NH_4)_2C_2O_4$  soln for complete pptn (usually  $\leq 1$  mL), cover beaker, and heat until ppt becomes granular enough to filter readily (incipient boiling 30 min usually suffices). Filter thru 5 or 7 cm fine texture paper into large Pt dish and wash thoroly with hot  $H_2O$  (5–6 fillings of filter usually suffice).

Evap. soln nearly to dryness on steam bath and add 1 mL  $H_2SO_4$  (1+1). Rotate dish so that  $H_2SO_4$  comes in contact with all residue, adding little  $H_2O$  if necessary. Return dish to steam bath and evap. all  $H_2O$  possible at that temp. Heat dish, preferably on hot plate, at ca  $150^\circ$  until bubbling caused by decomposition of oxalates ceases, and gradually increase temp. until  $H_2SO_4$  evaps. (When properly controlled, this treatment takes 45–90 min.) Cautiously heat sample over burner, being careful to avoid loss due to sputtering during decomposition of  $NH_4$  compds. Finally heat dish to redness to remove traces of  $NH_4$  compds and complete ignition. Cool, and add 5 drops  $HCl$  (1+1) to residue.

Transfer ash soln to 100–200 mL r-b porcelain dish, using ca 50 mL hot  $H_2O$ . Add small excess  $H_2PtCl_6$  soln. Place mixt. on steam bath and rotate dish from time to time to prevent ppt from baking on side of dish, and evap. to paste. (It is advisable to start evapn with several steam bath rings removed, and as concn progresses, to replace rings so that heat is applied only to surface of dish covered by liq.) Avoid exposure to  $NH_3$  fumes at all times.

Add ca 50 mL 90% alcohol to dish and transfer to gooch with asbestos mat, or 30 mL gooch with medium porosity fritted disk. Wash 8 or 10 times with 20 mL portions 90% alcohol; then 5 or 6 times with 10 mL portions  $NH_4Cl$  soln, (a). Again wash thoroly 6 or 8 times with 20 mL portions 90% alcohol.

Dry ca 30 min in  $100^\circ$  oven, cool, and weigh. Wash the  $K_2PtCl_6$  thru gooch with hot  $H_2O$ , using slight suction; then wash gooch with alcohol, dry, cool, and weigh. Difference in wt  $\times 0.1938 = K_2O$ . Report results as mg/100 g original sample.

(b) *Short gravimetric chloroplatinate method*.—Proceed as in (a), pars. 3–5, using ash soln, **22.030**, from ash, **22.028(a)**.

★(c) *Short volumetric chloroplatinate method*.★—See **22.022(c)**, 10th ed.

★(d) *Long volumetric chloroplatinate method*.★—See **22.022(d)**, 10th ed.

**22.032 ★ Gravimetric Cobaltinitrite Method ★**

See **22.026–22.027**, 11th ed.

**22.033 Rapid Flame Photometric Method(15)  
Official Final Action**

(Caution: See **51.007**.)

Prep. sample soln as in **22.008**. Dil., if necessary, to reduce K concn to range covered by flame photometer (preferably 40–80 ppm). Aspirate sample soln (dild or undild) directly into flame.

Prep. stds as in **11.024(a)** except cover range 10–100 ppm K in 10 ppm steps. Det. %T for stds or follow instructions of

manufacturer, making check detns as necessary. If internal std instrument is used, add appropriate amt of  $LiCl$  to both std and sample solns.

From %T of sample and std curve, det. ppm K. Report as mg  $K_2O/100$  g sample.  $K \times 1.2046 = K_2O$ .

**Sodium (16)—Official Final Action**

(Caution: See **51.007**.)

**22.034****Reagents and Apparatus**

(a) *Sodium std solns*.—Dry reagent grade  $NaCl$  at  $100^\circ$  overnight and dil. 2.5422 g to 1 L with  $H_2O$ . (Soln contains 1000 ppm Na.) Dil. 10 mL to 100 mL, and further dil. 1, 2, 4, 6, 8, and 10 mL dild soln to 100 mL to make std solns contg, resp., 1, 2, 4, 6, 8, and 10 ppm Na. Store in clean, dry polyethylene bottles.

(b) *Flame spectrophotometer*.—See **11.024(b)**.

**22.035****Determination**

Prep. sample soln as in **22.008**. Dil., if necessary, to reduce Na concn to range covered by flame photometer (preferably 4–10 ppm Na). Aspirate sample soln (dild or undild) directly into flame.

Det. %T for stds and plot curve of %T against ppm Na. Det. %T for sample and use std curve to det. ppm Na in sample or follow instructions of manufacturer, making check detns as necessary. If internal std instrument is used, add appropriate amt of  $LiCl$  to both std and sample solns.

Report as mg  $Na_2O/100$  g sample.  $Na \times 1.3480 = Na_2O$ .

**22.036 ★ Manganese (17)—Official First Action ★**

(Caution: See **51.047** and **51.081**.)

See **20.026–20.027**, 10th ed.

**★ Calcium (18)—Official First Action ★****22.037 Double Precipitation Method**

See **20.028**, 10th ed.

**22.038 Single Precipitation Method**

See **20.029**, 10th ed.

**22.039 ★ Magnesium (19)—Official First Action ★**

See **20.030**, 10th ed.

**Phosphorus****22.040 ★ Volumetric Method (20) ★  
Official Final Action**

(Not applicable to acid fruit products stored for appreciable time in tin cans)

Pptn as phosphomolybdate, soln in excess std  $NaOH$ , and back titrn of excess alkali (see **14.029**). See **22.039–22.040**, 12th ed.

**22.041 ★ Colorimetric Method (21) ★**

See **22.037–22.039**, 11th ed.

★ Surplus method—see inside front cover.

**Spectrophotometric Molybdovanadate Method (22)  
Official First Action**

(Do not clean glassware with P-contg detergents.)

**22.042****Apparatus and Reagents**

(a) *Spectrophotometer*.—Prism or grating, with matched 1 cm cells.

(b) *Molybdovanadate reagent*.—Dissolve 60 g  $\text{NH}_4$  molybdate,  $4\text{H}_2\text{O}$  in 900 mL hot  $\text{H}_2\text{O}$ , cool, and dil. to 1 L. Dissolve 1.5 g  $\text{NH}_4$  metavanadate in 690 mL hot  $\text{H}_2\text{O}$ , add 300 mL  $\text{HNO}_3$ , cool, and dil. to 1 L. Gradually add molybdate soln to vanadate soln with stirring. Store at room temp. in polyethylene or g-s Pyrex bottle. (Reagent is stable indefinitely in polyethylene, but in Pyrex, ppt gradually forms after several months. Discard reagent if ppt forms.)

(c) *Phosphate std solns*.—(1) *Stock soln*.—0.5 mg  $\text{P}_2\text{O}_5$ /mL. Dissolve 0.2397 g pure (if assay <100%  $\text{KH}_2\text{PO}_4$ , 0.2397 g  $\times$  100/%  $\text{KH}_2\text{PO}_4$  = correct wt) and dried (2 hr at  $105^\circ$ ) primary std  $\text{KH}_2\text{PO}_4$  in  $\text{H}_2\text{O}$  and dil. to 250 mL. (2) *Working solns*.—Dil. 0, 5, 10, 15, 20, 25, 30, and 35 mL stock soln to 500 mL to obtain 0.00, 0.05, 0.10, 0.15, 0.20, 0.25, 0.30, and 0.35 mg  $\text{P}_2\text{O}_5$ /10 mL, resp.

**22.043****Preparation of Standard Curve**

(Caution: See 51.018 and 51.026.)

Pipet 10 mL of each working std soln into 25 mL erlenmeyers and stopper immediately to prevent evapn. As rapidly as possible for entire series, pipet 5 mL molybdovanadate reagent into each, stopper, and mix. Let stand 10 min for color development and read  $A$  of each soln within 1 hr.

Fill 4 matched cells with 0.00 mg std. Set spectrophtr at 400 nm and adjust to 0  $A$  with 1 cell. Read each cell  $A$  against this cell. Use cell with lowest  $A$  with 0.00 mg std in future measurements. If  $A$  of 0.00 mg std in other cells are >0.001 against this std in ref. cell, subtract these  $A$  from subsequent readings. Det.  $A$  of each std with instrument adjusted to 0  $A$  for 0.00 mg std. After every 3 detns, refill cell contg 0.00 mg std to avoid error due to evapn and temp. changes. Plot  $A$  against mg  $\text{P}_2\text{O}_5$ /10 mL (vol. working std soln).

(Note: Use Pyrex dropper to fill and empty cells. Do not remove cells from holder. Use dropper tube with greater capacity than cell to prevent liq. from entering bulb. Bulb should be just large enough that cell can be filled or emptied in one operation. Rinse cell with succeeding std or sample soln. Use different dropper to fill and empty ref. cell.)

**22.044****Preparation of Sample**

Proceed as in 22.026. (Add 1 teaspoon sucrose to samples low in sugar to speed ashing.) Dissolve ash in 10 mL  $\text{HCl}$  (1+3) and evap. to dryness on steam bath. Dissolve residue in 10 mL  $\text{HCl}$  (1+9) on steam bath and transfer to 100 mL vol. flask. Cool, dil. to vol., and mix. Filter thru dry paper if any insol. matter is present. If ash has >3.5 mg  $\text{P}_2\text{O}_5$ , dil. to >100 mL or make secondary dilns so 10 mL aliquot contains <0.35 mg  $\text{P}_2\text{O}_5$ . (See Watt, B. K., and Merrill, A. L., *Composition of Foods*, USDA Handbook No. 8, p. 6–67, Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402, rev. Dec. 1963, for data on P content of fruit products and other foods.) If ash wt is not desired, use smaller sample aliquot to reduce drying and ashing time.

**22.045****Determination**

Into sep. 25 mL erlenmeyers pipet 10 mL aliquots std solns contg 0.00 and 0.20 mg  $\text{P}_2\text{O}_5$ /10 mL. Develop color as for std curve. Adjust instrument to 0  $A$  for 0.00 mg std and det.  $A$  of 0.20 mg std. ( $A$  of this std should be within  $\pm 1\%$  of  $A$  of std

curve; if not, prep. new std curve.) Develop color and det.  $A$  of sample ash solns concurrently with and in same manner as for std solns. Calc. as follows:

(a) *From std curve*.—mg  $\text{P}_2\text{O}_5$ /100 g sample =  $100 \times (\text{mg } \text{P}_2\text{O}_5/10 \text{ mL from std curve})/\text{g sample in 10 mL ash soln}$ .

(b) *From formula*.—mg  $\text{P}_2\text{O}_5$ /100 g sample =  $A \times S \times 100/W$ , where  $A$  refers to sample soln at 400 nm,  $S$  = slope of std curve =  $(\Sigma r)/n$ ;  $\Sigma r$  = sum of ratios of mg  $\text{P}_2\text{O}_5$ /10 mL to  $A$  of each std, and  $n$  = number of std solns used in calcns; and  $W$  = g sample in 10 mL ash soln.

**Gravimetric Quinoline Molybdate Method  
(22)—Official First Action**

**22.046****Reagent**

See 2.026(c).

**22.047****Preparation of Sample**

Prep. as in 22.044, but transfer  $\text{HCl}$  (1+9) soln of residue to 500 mL erlenmeyer, filtering if any insol. matter is present. If sample ash has >25 mg  $\text{P}_2\text{O}_5$  (see Watt and Merrill, 22.044), dil. to 100 mL or other definite vol. and use aliquot contg <25 mg  $\text{P}_2\text{O}_5$ . Dil. soln to ca 100 mL with  $\text{H}_2\text{O}$ .

**22.048****Determination**

Proceed as in 2.028(b), except boil 3 min. Report results as mg  $\text{P}_2\text{O}_5$ /100 g.

**22.049 ★ Sulfur in Ash (23)—Official Final Action ★**

(For products contg a basic ash)

Gravimetric detn of pptd  $\text{BaSO}_4$ . See 22.050, 12th ed.

**22.050 ★ Total Sulfur (24)—Official First Action ★**

(For sulfured products and for samples  
contg little ash or acidic ash)

Gravimetric detn of pptd  $\text{BaSO}_4$ . See 22.050, 12th ed.

**22.051 Total Chlorine (25)—Official First Action**

See 3.071–3.074.

**22.052 ★ Alcohol Precipitate (26) ★  
Official First Action**

Gravimetric detn of alcohol ppt. See 22.052, 12th ed.

**22.053 ★ Pectic Acid (27)—Official First Action ★**

Pptn of pectin with alcohol, soln in alkali, repptn with acid,  
and weighing. See 22.053, 12th ed.

**22.054 Protein—Official Final Action**

Proceed as in 2.057, using 5 g jelly or other fruit product contg  
large amt of sugar, or 10 g juice or fresh fruit, and larger amt  
of  $\text{H}_2\text{SO}_4$  if necessary for complete digestion. % N  $\times$  6.25 = %  
protein.

**Betaine (28)—Official First Action**

(Applicable to orange juice)

**22.055****Reagents**

(a) *Ammonia soln*.—2%. Dil. 140 mL  $\text{NH}_4\text{OH}$  to 2 L with  $\text{H}_2\text{O}$ .

(b) *Ammonium reineckate soln*.—2.5%. Shake 2.5 g in 75 mL

★ Surplus method—see inside front cover.

H<sub>2</sub>O 30 min. Filter thru paper and dil. to 100.0 mL. Adjust pH to 1.0 with HCl and filter thru fine porosity glass crucible. Prep. fresh before betaine pptn. Do not use reagent contg ppt.

(c) *Acetone soln.*—70%. Dil. 70 mL to 100 mL with H<sub>2</sub>O.

(d) *Aqueous ether.*—Add 1 mL H<sub>2</sub>O to 140 mL ether.

(e) *Ion exchange resins.*—(1) *Amberlite IR-120 medium porosity (20–50 mesh, wet).*—Prep. 250 g in H form by treating with 2 bed vols 2*N* HCl (ca 500 mL). Soak 2 hr. Drain resin and wash with H<sub>2</sub>O until neut. and Cl-free. (2) *Amberlite IRA-400 (20–50 mesh, wet).*—Prep. 250 g in OH form by treating with 2 bed vols 2*N* NaOH (ca 500 mL). Drain and wash NaOH-free with H<sub>2</sub>O. Mix with IRC-50 immediately for column II prep. (3) *Amberlite IRC-50.*—Prep. 125 g in H form by treating with 2 bed vols 2*N* HCl. Drain and wash Cl-free with H<sub>2</sub>O.

(f) *Betaine std soln.*—1 mg anhyd. betaine/mL. Weigh 0.2623 g betaine.HCl in 200 mL vol. flask and dil. to vol. with H<sub>2</sub>O.

## 22.056

### Preparation of Columns

(a) *Column I.*—Use 18 mm id chromatgc tube with medium or coarse porosity fritted glass and with stopcock. Add aq. slurry Amberlite IR-120(H) to 12.5 cm bed depth (wet resin). To regenerate resin, pour thru 100–200 mL 1*N* HCl and wash Cl-free with H<sub>2</sub>O.

(b) *Column II.*—Intimately mix 2 vols Amberlite IRA-400(OH) with 1 vol IRC-50(H) and transfer to column as above to 7.5 cm bed depth. Resins have different densities, and excess H<sub>2</sub>O causes undesirable sepn. Bed must be intimate mixt. Resin mixt. cannot be regenerated. Use for 2 detns only.

## 22.057

### Preparation of Sample

Prep. juice as in 22.008(a).

## 22.058

### Determination

Add accurately measured amt prepd juice (10–20 mL) contg 5–7 mg betaine to small beaker. Dil. to ca 30 mL with H<sub>2</sub>O and adjust to pH 3.0 with 0.1*N* HCl, using pH meter. Transfer to column I. Collect eluate at ca 3 mL/min. When liq. reaches top of resin, wash column with 200 mL H<sub>2</sub>O or until carbohydrate-free. Discard eluate and wash soln. Elute betaine by washing column with  $\geq 150$  mL 2% NH<sub>4</sub>OH, ensuring eluate is alk. Follow with 100 mL H<sub>2</sub>O. Reduce eluate to ca 25 mL by boiling. Cool, adjust to pH 7.0 with 0.1*N* HCl, and transfer to Column II. (Reduce vol. in erlenmeyer and then transfer to small beaker for pH adjustment.)

Collect eluate at 1 mL/min. When liq. reaches top of resin bed, wash with 50 mL H<sub>2</sub>O. Conc. combined eluates and washings to 15–20 mL, cool, and adjust to pH 1.0 with 1*N* HCl. Cool to 0 $\pm$ 3° and gradually add, with stirring, 20 mL 2.5% NH<sub>4</sub> reineckate, adjusted to pH 1.0 and cooled to 0 $\pm$ 3°. Let stand 3 hr at 0 $\pm$ 3°. Filter while cold thru medium porosity 60 mL fritted glass crucible with vac. Transfer ppt with small amts cold filtrate. Wash ppt with three 5 mL portions aq. ether. Dissolve ppt in 10 mL 70% acetone and transfer to 25 mL vol. flask. Dil. to vol. with 70% acetone. Det. A at 525 nm on spectrophtr, using 1 cm cell, against 70% acetone as ref. (Make readings within 4 hr.) Det. amt betaine from std curve.

## 22.059

### Preparation of Standard Curve

Transfer 2.5, 5.0, 7.5, 10.0, 12.5, and 15.0 mL betaine std soln to beakers, using 10 mL buret. Add H<sub>2</sub>O to ca 20 mL and proceed as in 22.058, beginning, "... adjust to pH 1.0 with 1*N* HCl."

Plot of mg anhyd. betaine/mL against A should be straight line.

## Titrateable Acidity (29)—Official Final Action

### 22.060 Indicator Method

(a) *Colorless or slightly colored solns.*—Dil. to ca 250 mL, with neutrd or recently boiled H<sub>2</sub>O, 10 g prepd juice, 22.008(a), or 25 mL prepd soln, 22.008(b) or (c). Titr. with 0.1*N* alkali, using 0.3 mL phthln for each 100 mL soln being titrd, to pink persisting 30 sec. Report as mL 0.1*N* alkali/100 g or 100 mL original material.

(b) *Highly colored solns.*—Dil. sample of known wt with neutrd H<sub>2</sub>O and titr. to just before end point with 0.1*N* alkali, using 0.3 mL phthln for each 100 mL soln being titrd. Transfer measured vol. (2 or 3 mL) of soln into ca 20 mL neut. H<sub>2</sub>O in small beaker. (In this extra diln, color of fruit juice becomes so pale that phthln color is easily seen.) If test shows that end point is not reached, pour extra dild portion back into original soln, add more alkali, and continue titrn to end point. By comparing dilns in small beakers, differences produced by few drops 0.1*N* alkali can be easily observed.

## Glass Electrode Method—Official First Action

### 22.061

#### Determination

Before use, check app. with std buffer solns, 50.007 and Table 50.02. Rinse glass electrode in H<sub>2</sub>O several times until reading is ca pH 6. Immerse electrodes in sample contained in beaker. (Sample should titr. 10–50 mL 0.1*N* NaOH and be contained in initial vol. of 100–200 mL.) Stir moderately. Add alkali quite rapidly until near pH 6. Then add alkali slowly to pH 7. After pH 7 is reached, finish titrn by adding 0.1*N* alkali 4 drops at time, and record total vol. and pH reading after each addn. (Add whole drops, so that fraction of drop does not remain on buret tip.) Continue titrn  $\geq 4$  drops beyond pH 8.1, and interpolate data for titrn corresponding to pH 8.1. pH values used for interpolation should lie in range 8.10 $\pm$ 0.2.

*Notes:* (1) Always keep glass electrode covered with H<sub>2</sub>O when not in use.

(2) If strongly acid cleaning solns are used, electrode requires several hr to come to equilibrium on standing in H<sub>2</sub>O.

(3) If electrode and stirrer are wiped lightly with piece of filter paper before insertion into std buffer, same soln may be used for several checks on instrument.

## 22.062 Volatile Acidity—Official Final Action

Dissolve 10 g sample, dil. to 25 mL, and steam distil as in 11.040. 1 mL 0.1*N* alkali = 0.0060 g HOAc.

## Total Tartaric Acid (30)

### 22.063 ★ Bitartrate Method—Official Final Action ★

Removal of pectin with alcohol, pptn of org. acids as Pb salts, removal of Pb with H<sub>2</sub>S, and pptn of K bitartrate which is titrd with alkali. See 22.063–22.065, 12th ed.

## Citric Acid

### 22.064 ★ Pentabromacetone Method (31) ★ Official Final Action

Removal of pectin with alcohol, pptn of org. acids as Pb salts, removal of Pb with H<sub>2</sub>S, and oxidn of citric acid with KMnO<sub>4</sub> in presence of bromide to insol. pentabromacetone which is detd gravimetrically. See 22.066–22.069, 12th ed.

★ Surplus method—see inside front cover.

**22.065 ★ Total Malic Acid (Laevo- and Inactive) (32) ★**  
**Official First Action**

(Either isocitric acid or tartaric acid or both may be present.)

Removal of pectin with alcohol, pptn of org. acids as Pb salts, removal of Pb with  $H_2S$ , sepn of liberated acids by silica gel chromatography, and titrn of malic acid fraction with alkali. See 22.070–22.073, 12th ed.

**Citric and Isocitric Acids**

**22.066 ★ Chromatographic Method (33) ★**  
**Official First Action**

Org. acids pptd as Pb salts, liberated with  $H_2SO_4$ , and incorporated into silica gel column. Citric acid fraction is titrd to det. total citric acid. Normal citric acid is detd by volumetric penta-bromacetone method and isocitric acid is detd by difference. See 22.074–22.077, 12th ed.

**Laevo-Malic Acid**

**22.067 ★ Method I (34)—Official First Action ★**

Removal of pectin with alcohol, pptn of org. acids as Pb salts, removal of Pb with  $H_2S$  and tartaric acid as K bitartrate, repptn of org. acids as Pb salts, removal of Pb with  $H_2S$ , and detn of laevo-malic acid polariscopically as the uranyl complex. See 22.078–22.080, 12th ed.

**22.068 ★ Method II (35)—Official First Action ★**

(Not applicable in presence of isocitric acid—blackberry)

Caution: See 51.083 and 51.084.)

Laevo-malic acid is detd polariscopically as uranyl complex in filtrate from tartaric detn, 22.063★, after decolorization with C. See 22.081, 12th ed.

**Method III (36)—Official First Action**

(Caution: See 51.083 and 51.084.)

**22.069**

**Apparatus and Reagents**

- (a) *Polarimeter*.—Accurate to  $0.01^\circ$ , with Na lamp.  
 (b) *Carbon*.—Activated, acid-washed (Darco G-60, or equiv.).  
 (c) *L-Malic acid*.—Calbiochem A Grade, or equiv. Must meet following purity test: Dissolve 0.5 g (–)malic acid in ca 50 mL  $H_2O$ , adjust pH to 5.5 with 1N NaOH, and dil. to 100 mL with  $H_2O$ . To ca 35 mL, add 1.5 g uranyl acetate.  $2H_2O$  and let stand in dark 30 min. Filter, and read optical rotation in 200 mm tube. Optical rotation of  $\alpha = -4.88^\circ$  to  $-4.84^\circ$  should be obtained.

(d) *L-Malic acid std solns.*—(1) *Stock soln.*—10 mg/mL. Place 1.0 g *L*-malic acid and 4.0 g citric acid in 150 mL beaker, add ca 50 mL  $H_2O$ , and adjust to pH 5.5 with 50% NaOH soln, using pH meter and mag. stirrer. Quant. transfer to 100 mL vol. flask and dil. to vol. with  $H_2O$ . (2) *Working solns.*—1, 2, and 3 mg/mL. Pipet 10, 20, and 30 mL stock soln to sep. 100 mL vol. flasks and dil. to vol. with  $H_2O$ .

**22.070**

**Preparation of Standard Curve**

Det. optical rotation ( $\alpha_1$ ) of each std soln in 200 mm polarimeter tube. To ca 35 mL of each std soln in 50 mL erlenmeyer, add 1.5 g uranyl acetate.  $2H_2O$ . Keep in dark 30 min and swirl occasionally. Filter and det. optical rotation ( $\alpha_u$ ) of clear uranyl malate complex in 200 mm polarimeter tube. Plot mg *L*-malic acid/100 mL against difference in rotation ( $\alpha = \alpha_u - \alpha_1$ ).

★ Surplus method—see inside front cover.

**22.071**

**Preparation of Sample**

(a) *Fruit juices*.—Weigh 62.5 g into 250 mL vol. flask. Add 0.1 g KOAc and 100 mL alcohol, and mix. Dil. to vol. with alcohol, mix, and let stand 1 hr. Filter thru rapid paper.

(b) *Preserves and high-sugar content products containing pieces of fruit*.—Comminute, and weigh 62.5 g into 250 mL beaker. Add 0.1 g KOAc, 30 mL  $H_2O$ , and 100 mL alcohol, mix, and transfer quant. to 250 mL vol. flask, using alcohol. Dil. to vol. with alcohol, mix, and let stand 1 hr. Filter thru rapid paper.

(c) *Fruit*.—Comminute, and weigh 62.5 g into 250 mL beaker. Proceed as in (b) except omit addn of 30 mL  $H_2O$ .

(d) *Grape juice*.—Weigh 125 g into 500 mL vol. flask, add 1.0 mL satd KOAc soln and 200 mL alcohol, and mix. Dil. to vol. with alcohol, mix, and let stand overnight. Filter thru Whatman No. 40 paper, or equiv.

(e) *Grape preserves and other high-sugar content grape products*.—Comminute, and weigh 125 g into 500 mL beaker. Add 1.0 mL satd KOAc soln, 50 mL  $H_2O$ , and 200 mL alcohol. Mix and transfer quant. to 500 mL vol. flask with alcohol. Dil. to vol. with alcohol, mix, and let stand overnight. Filter thru Whatman No. 40 paper, or equiv.

(f) *Grapes*.—Comminute, and weigh 125 g into 500 mL beaker. Proceed as in (e) except omit addn of 50 mL  $H_2O$ .

**22.072**

**Determination**

Transfer 200 mL aliquot filtrate to 250 mL (8 oz) wide mouth bottle, 5.7 cm od  $\times$  13 cm high ( $2.25 \times 5$ ). Add mag. stirring bar and 30 mL absolute alcohol. Potentiometrically titr. 10 mL remaining filtrate to pH 8.4, using 0.1N NaOH. Calc. mL NaOH necessary to neutze the 200 mL aliquot. Add to bottle 0.6 mL satd  $Pb(OAc)_2$  soln for each mL 1N NaOH calcd to neutze 200 mL aliquot. Stir 10 min with mag. stirrer and centrf. 6 min at 1500 rpm. Test supernate for complete pptn with few drops satd  $Pb(OAc)_2$  soln. Decant and wash ppt by stirring 5 min with 200 mL alcohol. (Use 85% alcohol with grapes and grape products.) Centrf. 5 min, decant, add 25 mL  $H_2O$  to ppt, and mix well to slurry. Use pH meter and adjust pH to 1.5 with  $H_2SO_4$  (1+9). Remove  $PbSO_4$  by vac. filtration on coarse porosity 60 mL fritted glass crucible contg asbestos pad. Wash ppt with 10 mL portions  $H_2O$  and combine washings with filtrate in 150 mL graduated beaker. Total vol. should be  $<90$  mL. Adjust pH to 5.5 with 50% NaOH, using pH meter. Transfer quant. to 100 mL vol. flask and dil. to vol. with  $H_2O$ . Add ca 6 g C and mix thoroly. Let stand 30 min and filter thru fine paper. Filtrate must be colorless. Det. optical rotation ( $\alpha_1$ ) on this filtrate, using 200 mm tube. To ca 35 mL filtrate in 50 mL erlenmeyer add 1.5 g uranyl acetate.  $2H_2O$  and keep in dark 30 min with occasional swirling. Filter and det. optical rotation ( $\alpha_u$ ) of clear soln of uranyl malate complex. Calc. mg *L*-malic acid/100 g sample by one of following:

(a)  $(\alpha_x \times C \times 100)/(\alpha_s \times W)$ , where  $\alpha_x$  = difference in rotation of sample =  $\alpha_{ux} - \alpha_{1x}$ ;  $\alpha_s$  = difference in rotation of std =  $\alpha_{us} - \alpha_{1s}$ ;  $C$  = mg *L*-malic acid in 100 mL std soln; and  $W$  = g sample in 100 mL final soln.

(b)  $\alpha_x \times 2 \times (\text{sum of mg } L\text{-malic acid in std curve solns})/(\text{sum of number degrees in std curve solns})$ .

(c) (mg *L*-malic acid/100 mL) (from std curve)  $\times 2$ .

**Inactive Malic Acid (37)—Official First Action**

(As method is empirical, all directions must be rigidly followed, particularly with respect to dilns. Substitution of vol. flasks of capacities different from those specified is not permissible.)

**22.073**

**Reagents**

(a) *Lead acetate soln*.—Dissolve 40 g  $Pb(OAc)_2 \cdot 3H_2O$  in  $H_2O$ , add 0.5 mL HOAc, and dil. to 100 mL.

(b) *Tribasic lead acetate std soln.*—Prep. soln from tribasic  $\text{Pb}(\text{OAc})_2$ , (c). To 5 g of the salt in 500 mL erlenmeyer add 200 mL  $\text{H}_2\text{O}$  and shake vigorously. Neutze 3 mL 1N  $\text{H}_2\text{SO}_4$ , dild with 200 mL  $\text{H}_2\text{O}$ , with the soln, using Me red as indicator. Note vol. Pb soln required. In detn use 2 mL in excess of this vol. (Soln should be freshly prepd.)

(c) *Tribasic lead acetate.*—Dissolve 82 g  $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  in 170 mL  $\text{H}_2\text{O}$ . Prep 100 mL dil.  $\text{NH}_4\text{OH}$  soln contg 5.8 g  $\text{NH}_3$  as detd by titrn (Me red). Heat solns to 60°, mix thoroly, and let stand overnight. Shake vigorously to break up ppt, and filter on buchner. Wash once with  $\text{H}_2\text{O}$  and suck dry, then twice with alcohol, and finally with ether. Let dry in air.

(d) *Potassium permanganate std soln.*—Dissolve 14.5214 g purest  $\text{KMnO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L. Stdze as follows: Pipet 50 mL oxalic acid soln, (e), into 600 mL beaker and add 70 mL  $\text{H}_2\text{O}$  and 10 mL  $\text{H}_2\text{SO}_4$  (1+1). Heat to 80°, immediately add  $\text{KMnO}_4$  soln to faint pink, again heat to 80°, and finish titrn. 50 mL  $\text{KMnO}_4$  soln should be equiv. to 50 mL oxalic acid soln.

(e) *Oxalic acid std soln.*—Dissolve 28.7556 g purest  $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L (1 mL = 5 mg malic acid (laevo or inactive)).

## 22.074

### Preparation of Sample

Subject 2 portions of sample to isolation, 22.075(a); use one portion for detn of laevo-malic acid (polarization), 22.075(b), and other for total malic acid, laevo + inactive (oxidn), 22.075(c). Choose amt of sample with titratable acidity  $\leq 150$  mg acid calcd as malic acid. Designate as x mL 1N alkali required to neutze amt of sample chosen. In no case should solids content be  $> 20$  g (200 mL sample soln of jam or jelly).

Adjust sample soln to ca 35 mL by evapn or addn of  $\text{H}_2\text{O}$ , pour into 250 mL vol. flask, rinse with 10 mL hot  $\text{H}_2\text{O}$  and then with alcohol, and dil. to vol. with alcohol. Shake, let stand until pectin seps, leaving clear liq. (overnight if necessary), and filter thru folded paper, draining thoroly and covering funnel with watch glass. Pipet 225 mL filtrate into centr. bottle.

## 22.075

### Determination

(Caution: See 51.059.)

(a) *Isolation of total malic acid.*—To soln in centr. bottle add ca 25 mg citric acid and vol. of  $\text{Pb}(\text{OAc})_2$  soln, (a), equal to x (x + 3 mL if saponification was made), shake vigorously 2 min, and centr. Carefully decant supernate from pptd Pb salts and test with small amt of  $\text{Pb}(\text{OAc})_2$  soln. If ppt forms, return to centr. bottle, add more  $\text{Pb}(\text{OAc})_2$ , shake, and again centr. If sediment lifts, repeat centrfg, increasing speed and time. Let ppt drain thoroly by inverting bottle several min.

Add 200 mL 80% alcohol, shake vigorously, and again centr., decant, and drain. To Pb salts add ca 150 mL  $\text{H}_2\text{O}$ , shake vigorously, and pass in rapid stream of  $\text{H}_2\text{S}$  to saturation. Stopper bottle and shake ca 1 min. Transfer mixt. to 250 mL vol. flask with  $\text{H}_2\text{O}$ , dil. to vol., shake, and filter thru folded paper.

Pipet 225 mL filtrate into 600 mL beaker, and evap. to ca 100 mL to expel  $\text{H}_2\text{S}$ . Transfer to 250 mL vol. flask with  $\text{H}_2\text{O}$ . (Vol. in flask should be ca 200 mL.) Add 5 mL  $\text{HOAc}$  (1+9) and same amt of  $\text{Pb}(\text{OAc})_2$  soln previously used. Shake vigorously, dil. to vol. with  $\text{H}_2\text{O}$ , and filter.

Pass rapid stream of  $\text{H}_2\text{S}$  into clear filtrate to saturation, stopper flask, shake vigorously, and filter. Pipet 225 mL filtrate into 600 mL beaker, add ca 75 mg tartaric acid, and evap. over burner and gauze to ca 50 mL. Cool, neutze with 1N potassium hydroxide (phthln), and add 5 drops excess. Add 2 mL  $\text{HOAc}$  and transfer mixt. to 250 mL vol. flask with alcohol. Dil. to vol. with alcohol, shake, and pour into 500 mL erlenmeyer. Add

small handful of glass beads and cool to 15°. Stopper flask, shake vigorously 10 min, and place in refrigerator 30 min. Again shake 10 min and filter thru folded paper.

Adjust clear filtrate to 20° and pipet 225 mL into centr. bottle. Add  $\text{Pb}(\text{OAc})_2$  soln equal to x (x + 3 mL if saponification was made), shake vigorously ca 2 min, centr., decant, and drain. Add 200 mL 80% alcohol, shake, centr., decant, and drain.

Transfer Pb salts to 500 mL erlenmeyer with ca 175 mL  $\text{H}_2\text{O}$ . Add 3 mL 1N  $\text{H}_2\text{SO}_4$  and heat to bp; add 1 mL  $\text{HOAc}$  (5+95) and vol. std tribasic  $\text{Pb}(\text{OAc})_2$  soln previously detd in 22.073(b). Boil mixt. 5 min, cool to room temp., transfer to 250 mL vol. flask with  $\text{H}_2\text{O}$ , dil. to vol., shake, and pour into 500 mL erlenmeyer. Add small handful of glass beads, cool to ca 15°, shake vigorously 5 min, and place in refrigerator 30 min. Again shake 5 min and filter thru folded paper. Sat. clear filtrate with  $\text{H}_2\text{S}$ , shake vigorously, and filter. Use one of the two portions for polarization and other for oxidn.

(b) *Polarization.*—Evap. 225 mL clear filtrate over burner and gauze to ca 10 mL, neutze with 1N KOH (phthln), make slightly acid with  $\text{HOAc}$  (5+95), and evap. to ca 5 mL. Transfer to 25–27.5 mL Giles flask with  $\text{H}_2\text{O}$ , dil. to 27.5 mL mark, shake, and pour into small g-s erlenmeyer. If Giles flask is not available, use 25 mL graduate, dil. to vol., and add 2.5 mL  $\text{H}_2\text{O}$  from buret. Add small handful of glass beads and 4 g powd uranyl acetate, shake vigorously 10 min, and filter. (As U-malic complex is light sensitive, wrap flask in towel while shaking and protect from light as much as possible during filtration and polarization.) Polarize in 200 mm tube at 20°, using white light. After filling tube, release tension on glass disks by slightly loosening caps, and let stand  $\geq 30$  min at 20° before making readings. °S (31.020(a))  $\times 10.2$  = mg laevo-malic acid contained in aliquot (l in formula, (d)).

If control for adjusting to std temp. of 20° is lacking, det. temp. of polariscope and at this temp. prep. soln of U-complex as above. Make readings after letting tube remain in trough of instrument 30 min.

(c) *Oxidation.*—Evap. 225 mL clear soln to ca 10 mL to expel all alcohol, dil. to ca 120 mL with  $\text{H}_2\text{O}$ , and add 10 mL 30% NaOH soln and 25 mL  $\text{KMnO}_4$  soln. Heat to ca 80° and keep in boiling  $\text{H}_2\text{O}$  bath 30 min. Add 25 mL oxalic acid soln and 10 mL  $\text{H}_2\text{SO}_4$  (1+1), stirring vigorously. Adjust to 80°, and titr. to faint pink with  $\text{KMnO}_4$  soln. Again heat to 80° and finish titrn. mL  $\text{KMnO}_4$  soln used  $\times 5$  = total oxidizable material (as malic acid) present in aliquot (t in formula, (d)).

(d) *Calculation.*—Calc. mg inactive malic acid, X, in portion taken for analysis =  $4(t - 5 - l)$ , where t = mg oxidizable as malic acid; l = mg laevo-malic acid; 5 = correction factor for mg nonmalic material as malic acid; and 4 = factor for reverting inactive malic acid in aliquot back to amt of inactive acid in sample taken for analysis.

## 22.076 ★ Lactic Acid (38)—Official Final Action ★

Removal of pectin with alcohol, extn of lactic acid with ether, and spectrophtric detn as ferric lactate. See 22.089, 12th ed.

## Foreign Organic Acids (39)—Official First Action

(Caution: See 51.059.)

## 22.077

See 19.044.

## Apparatus

★ Surplus method—see inside front cover.

**22.078****Reagents**

(a) *Sodium acetate soln.*—Dissolve 15 g anhyd. NaOAc in H<sub>2</sub>O and dil. to 100 mL.

(b) *Lead acetate soln.*—Dissolve 8 g Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(c) *Std acid soln.*—Dissolve 1.5 g DL-malic acid, 0.85 g anhyd. citric acid, and 0.25 g tartaric acid in H<sub>2</sub>O, and dil. to 100 mL.

(d) *Aniline-furfural chromogenic agent.*—See 19.045(b)(1).

**22.079****Determination**

Place 10 mL single-strength juice in 50 mL capped centrif. tube, add 1 mL 1*N* HNO<sub>3</sub> and 25 mL alcohol, and mix. Centrif. and filter supernate thru small cotton plug into second 50 mL capped centrif. tube. Discard material in first tube. Add 1 mL NaOAc soln and 2.5 mL Pb(OAc)<sub>2</sub> soln to second tube and mix. Centrif. and discard supernate. Wash ppt with 25 mL portions 80% alcohol, 95% alcohol, and ether, successively mixing, centrifg. and discarding supernate each time. Let ether evap. spontaneously ca 10 min, add 2.0 mL H<sub>2</sub>O, and break up any lumps with narrow end of glass tube. Pass H<sub>2</sub>S thru this tube 5 min and then pass air thru same tube 5 min to remove excess H<sub>2</sub>S. Centrif. and decant clear supernate into small vial. In some cases it may be necessary to transfer material to 15 mL conical centrif. tube and centrif. until clear supernate is obtained.

Spot 20  $\mu$ L liq. on 12  $\times$  12" Whatman No. 1 chromatgc paper, using two 10  $\mu$ L portions and drying each spotting with warm air jet. Also spot 20  $\mu$ L std acid soln in same way. Develop paper as in 19.046, beginning "... roll paper and connect edges slightly apart ..." except use ether-HCOOH-H<sub>2</sub>O (20+5+3) developing solv.

After development, let paper air dry overnight. Treat portion of air-dried paper with aniline-furfural chromogenic agent by dipping and note color of background. If not pink, steam and dry paper as in 19.046, last par., to ensure complete removal of HCOOH.

If paper is pink, it need not be treated with steam. If background is dark, redistil furfural and prep. new chromogenic agent. Dip paper in chromogenic agent and let spots form by air drying. Note position and intensity of spots and compare with std acid soln. Top std spot (malic acid) has intensity value of I (intense); center spot (citric acid) has intensity value of D (dense); lowest spot (tartaric acid) has intensity value of F (faint). Classify acid spots obtained from juices as VI (very intense), I, D, F, or VF (very faint). Compare with chromatograms made simultaneously from pure fruit juices.

**Carbohydrates in Juices (40)—Official First Action****22.080****Apparatus**

*Gas chromatograph.*—Varian Aerograph Model 1520 (replaced by model 3720), with dual column and thermal detectors operated at 250° and 200 ma. GLC conditions: 1.8 m  $\times$  6 mm (6'  $\times$  1/4") stainless steel column packed with 3.8% SE-30 on 60–80 mesh silanized Diatoport S (replaced by Supelcoport, Supelco, Inc., or Chromosorb W-HP, Analabs, Inc.), programmed at 4°/min from 190 to 275° (for sharper sepn of sorbitol and glucose peaks, program at 2°/min until complete invert sugar pattern appears, and then at 4°/min); injector temp. 225°; He gas flow 40 mL/min; sample size and attenuation adjusted to give 50% full scale deflection for fructose peak.

**22.081****Reagents**

(a) *Neutral lead acetate soln.*—See 19.048(a).

(b) *Tri-Sil reagent.*—See 19.048(c).

**22.082****Determination**

Place 2.0 mL single-strength fruit juice in 15 mL capped centrif. tube, add 0.5 mL Pb(OAc)<sub>2</sub> soln and 10 mL alcohol, mix, and centrif. Decant clear supernate into small porcelain dish. Wash residue once with 5 mL 80% alcohol, mix, centrif., and add clear supernate to porcelain dish. Evap. to dryness on steam bath and keep on bath 15 min after apparent dryness. Ext sugars with five 2 mL portions hot pyridine, thoroly mixing each portion with residue and heating on steam bath during mixing. Filter each hot ext thru small glass wool plug into small flask. Cool combined exts and transfer 0.5 mL to 5 mL vial with Teflon-lined cap. Add few pieces of Drierite to vial; then add 2.0 mL Tri-Sil reagent. Let stand 1 hr at 37° and inject vol. soln such that fructose peak is ca half scale. (Turbidity in final soln does not affect GLC detn.) Compare curve with authentic sample prep'd in same way. Order of appearance is fructose,  $\alpha$ -glucose, sorbitol,  $\beta$ -glucose, and sucrose.

**Sucrose—Official Final Action****22.083 By Polarization**

Det. by polarizing before and after inversion. See 31.025, 31.026, or 31.030.

**22.084 By Reducing Sugars Before and After Inversion**

Transfer sample representing (if possible) ca 2.5 g total sugars to 200 mL vol. flask; dil. to ca 100 mL and add excess of satd neut. Pb(OAc)<sub>2</sub> soln, 31.021(d) (ca 2 mL is usually enough). Mix, dil. to vol., and filter, discarding first few mL filtrate. Add dry K or Na oxalate to ppt excess Pb used in clarification, mix, and filter, discarding first few mL filtrate. Take 25 mL filtrate or aliquot contg (if possible) 50–200 mg reducing sugars and proceed as in 31.038–31.039.

For inversion at room temp. transfer 50 mL aliquot clarified and deleadcd soln to 100 mL vol. flask, add 10 mL HCl (1+1), and let stand at room temp. ( $\geq 20^\circ$ ) 24 hr; exactly neutze with concd NaOH soln, using phthln, and dil. to 100 mL. Take aliquot and det. total sugars as invert as in 31.038–31.039. Calc. sucrose as in 31.031.

**22.085 Reducing Sugars—Official Final Action**

Proceed as in 22.084, par. 1. Express results as invert sugar.

**22.086 Commercial Glucose—Procedure**

See 31.033.

**Starch****22.087 Qualitative Test—Official Final Action**

Dil. portion of sample with H<sub>2</sub>O, heat nearly to bp, add several mL H<sub>2</sub>SO<sub>4</sub> (1+9), and then 10% KMnO<sub>4</sub> soln until all color is destroyed. Cool, and test with I soln, 30.029(d). (Presence of starch is not necessarily indication of its addn as adulterant. It is usually present in small amt in apples and occasionally in other fruits, and unless it is found in the fruit product in considerable amt its presence may be due to these natural sources.)

**Essential Oil (41)—Official First Action****22.088****Apparatus**

Use app. of 19.127, substituting 2 L flask with  $\S$  24/40 joint.

## 22.089

## Determination

Place 1 L sample in boiling flask and add few glass beads. Fill oil separatory trap with H<sub>2</sub>O, connect with boiling flask and condenser, and boil 1 hr. Remove heat and let stand several min. Drain enough H<sub>2</sub>O to bring oily layer within graduated portion of trap, let stand  $\geq 5$  min to complete drainage, and measure vol. of oil from bottom of lower meniscus to highest point of upper meniscus.

## Recoverable Oil (42)—Official Final Action

## 22.090

## Principle

Oil recoverable by distn from orange, tangerine, and grapefruit juices is  $\geq 98\%$  *d*-limonene, which, after co-distn with isopropanol, is detd after acidification by titrn with std KBr-KBrO<sub>3</sub> soln. Reaction involves release of Br *in situ* and subsequent formation of limonene tetrabromide. Oil from lemon juice contains up to 5%  $\alpha$ -pinene and 4% citral. Since  $\alpha$ -pinene consumes Br at same rate, and citral at  $\frac{1}{2}$  rate, as *d*-limonene, method is only slightly less accurate with lemon juice.

## 22.091

## Reagents

(a) *Potassium bromide-bromate std solns.*—(1) *Stock soln.*—0.099*N*. Prep. and stdze as in 50.020–50.021. (2) *Titration soln.*—0.0247*N*. Dil. stock soln 1+3. 1 mL 0.0247*N* KBr-KBrO<sub>3</sub> = 0.0010 mL (equiv. to 0.00084 g) *d*-limonene. Solns are stable 6 months.

(b) *Methyl orange indicator.*—0.1% in H<sub>2</sub>O. Use 1 drop per titrn, or add 5 mL to 1 L HCl (1+2).

## 22.092

## Apparatus

(a) *Electric heater.*—With recessed refractory top, 500–750 watts.

(b) *Still, all-glass.*—500 mL distn flask with  $\frac{3}{8}$  24/40 neck; 200 mm Graham condenser with 28/15 receiving socket and drip tip; connecting bulb and adapter. See Fig. 22:04.

(c) *Buret.*—10 mL, 0.05 mL subdivisions; suitable for rapid and dropwise titrn.

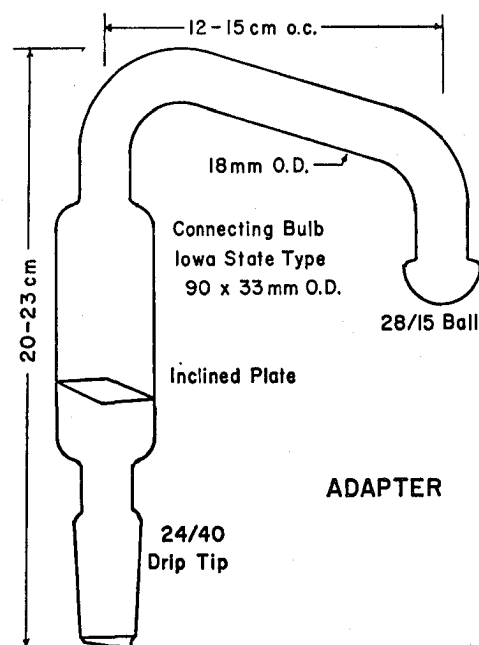

FIG. 22:04—Connecting tube adapter for direct distillation

## 22.093

## Determination

Preheat elec. heater. Pipet 25 mL well mixed sample into distn flask contg SiC chips or glass beads, and add 25 mL isopropanol. Distil into 150 mL beaker. Continue distn until solv. ceases to reflux, and remove flask, leaving heater on for next detn. Place short mag. bar in beaker, and add 10 mL HCl (1+2) and indicator. Titrn with std KBr-KBrO<sub>3</sub> while stirring. Major portion of titrant may be added rapidly, but end point (disappearance of color) must be approached at ca 1 drop/ sec.

Det. reagent blank by titrg 3 sep. mixts of 25 mL isopropanol, 10 mL HCl (1+2), and indicator without refilling buret. Total mL titrant/3 = av. blank.

% recoverable oil by vol. = (mL KBr-KBrO<sub>3</sub> soln used in titrn – mL av. blank)  $\times 0.001 \times 100/25$ .

## Anthocyanins (43)—Official Final Action

(Applicable to grape and dark colored fruit juices. *Caution:* See 51.017.)

## 22.094

## Apparatus

(a) *Chromatographic tank or cylinder.*—To hold cylinder made from 12  $\times$  12" Whatman No. 1 chromatgc paper. (18  $\times$  6" (46  $\times$  15 cm) glass cylindrical tank, with ground top and glass cover, is convenient.)

(b) *Spectrophotometer.*—Beckman Model DU, Bausch & Lomb Spectronic 20, or equiv.

## 22.095

## Reagents

(a) *Lead acetate soln.*—See 22.078(b).

(b) *Developing solvent.*—*n*-BuOH-HOAc-H<sub>2</sub>O (6+1+2).

(c) *Modified Forestal solvent.*—Dissolve 0.5 g oxalic acid in 60 mL H<sub>2</sub>O, add 30 mL HCl and 150 mL HOAc, and mix.

(d) *Chromogenic spray.*—2% phosphomolybdic acid in H<sub>2</sub>O.

(e) *Eluting solvent.*—Dissolve 0.2 g oxalic acid in 100 mL alcohol, add 0.2 mL HCl, and mix.

## 22.096

## Extraction of Anthocyanins

Add 10 mL Pb(OAc)<sub>2</sub> soln to 10 mL single-strength juice in 50 mL screw-cap centr. tube and mix. Add 0.5 mL NH<sub>4</sub>OH and mix. Centrf. until ppt is well packed and discard clear supernate. (If supernate is not clear, add more Pb(OAc)<sub>2</sub> soln and recentrf.) Wash ppt twice with 25 mL portions 80% alcohol, mixing well each time before centrfg; discard washings. After second wash, invert tube 5 min to drain liq. Add 10 mL *n*-BuOH and 1 mL HCl, shake vigorously until all colored ppt has been transformed into PbCl<sub>2</sub>, and centrfg. Decant clear liq. into 125 mL separator. Wash ppt with 5 mL *n*-BuOH, mix well, and centrfg. to obtain clear upper liq. Add washings to first ext in separator. Add 100 mL pet ether to separator, shake well, and swirl to bring down colored aq. soln. (If no aq. liq. seps, add 0.5 mL H<sub>2</sub>O, shake, and swirl.) Let liqs sep. completely and drain lower aq. layer (usually ca 2 mL) into 15 mL conical graduated centr. tube. Add 0.2–0.5 mL portions H<sub>2</sub>O to separator, shaking each time and draining lower layers, until total of 2.5 mL is collected. (Occasionally,  $\geq 2.5$  mL will be collected in first sepn of liqs; make no addnl H<sub>2</sub>O extns in this case.) Mix soln and use 0.5 mL for chromatgc test for anthocyanin. Retain anthocyanin soln in refrigerator until used.

## 22.097

## Preparation of Anthocyanidins

Add equal vol. 2*N* HCl to liq. in centr. tube contg small boiling chip. Fit tube with air condenser made from glass tubing and cork. Place tube in boiling H<sub>2</sub>O bath and heat 30 min. Remove from bath and cool in H<sub>2</sub>O. Add 1 mL isoamyl alcohol, shake

vigorously, and centr. With glass tube drawn out to capillary tip at one end and small bulb, transfer clear, upper layer to small bottle. (Do not remove any turbid aq. liq. in tube.) Keep anthocyanidin soln in refrigerator until used.

**22.098****Chromatography**

Use 12 × 12" Whatman No. 1 papers for tests (a) and (b). Papers require overnight development; prep. in late afternoon to permit 16 hr development.

(a) *Qualitative anthocyanin ascending paper chromatography*.—(Definitive for fruit juices other than grape juice; not definitive for grape juice where pattern is extremely complicated, but may be useful as guide.) Prep. streaks of soln, **22.096**, 2.5 cm above bottom of paper and ca 2.5 cm apart. Make streaks 3 cm long and 0.3–0.6 cm wide, using capillary mp tube, **22.101(c)**. Concord grape juice requires 5–7 applications to obtain satisfactory intensity; other juices usually require more; some may require fewer. Make 2 sep. streakings from same soln, using different intensities, one of which may yield better chromatgc pattern. Dry between each application with cold air blast only. After streakings are completed, dry streaks, and make cylinder of paper by sewing ends with cotton, leaving ca 1 cm space between ends. (Do not use metal clips to make cylinder.) Place developing solv., (b), to ca 1 cm depth in tank and place cylinder in tank. Let develop overnight at room temp., remove paper, and air dry.

Simultaneously test authentic fruit juice anthocyanins and compare patterns. Note differences in daylight and under long-wave UV light. Spray with phosphomolybdic acid soln and observe changes in pattern. Foreign natural coloring material is indicated by significant differences from authentic pattern.

(b) *Quantitative anthocyanidin ascending paper chromatography*.—(Definitive for grape juice but optional for other fruit juices.) Pipet 0.10 mL anthocyanidin soln, **22.097**, into small flask, add 10.0 mL eluting solv., and mix. Read *A* at 545 nm in 1 cm cell. Calc. vol. anthocyanidin soln to give *A* of 0.400 under these conditions; use this vol. for transfer to chromatgc paper.

Place calcd vol. anthocyanidin soln in small test tube. Using capillary tube, make successive applications on paper, each ca 3 cm long and 0.5 cm wide. Keep different sample streaks ca 2.5 cm apart. Dry each application with cold air blast before applying next streak. Prep. streaked paper as in (a).

Develop overnight (16 hr) at room temp., using Forestal solv. Air dry and examine under longwave UV light. (3 distinct orange to red spots should be present. For juices other than grape, compare pattern with authentic pattern. If no differences in intensities of the 3 spots are noted, it is not necessary to make quant. measurements of the anthocyanidin colors.) Alternatively, measure intensity of colors in spots with densitometer, using green filter. (Expose paper to HCl fumes few min before using densitometer.)

Elute colors and measure in spectrophtr as follows: Outline top spot and bottom 2 spots with soft pencil under longwave UV light. Cut out top spot, and cut it into several small pieces before transferring to screwcap test tube or small g-s erlenmeyer. Cut out each of 2 lower spots, starting ca 0.6 cm above origin line for lowest spot. Combine these 2 spots for grape juice, but keep sep. for other juices. Cut strips into several smaller pieces and place in test tube(s) or flask(s). Pipet 10 mL eluting solv., (e), into each tube or flask, and agitate 1 hr. (Rotating device can be used with test tubes and agitator with flasks. In absence of agitating device, let eluting soln remain in contact with paper 3 hr in dark, with occasional swirling.) Centr. alc. exts in 15 mL conical centr. tube and decant clear, upper liq. for color measurements. Cover cells while reading to avoid evapn. Read *A* at

445, 545, and 645 nm. Correct 545 nm (max.) readings for background by subtracting ½ algebraic sum of 445 and 645 nm readings.

Designate the 3 spots as S1 (lowest), S2 (central), and S3 (top) spots. Calc. % color in each spot of total color (S1 + S2 + S3), using corresponding corrected *A*. Significant differences from authentic % indicate presence of foreign coloring.

Concord anthocyanidins show deeply colored S1 and S2 spots while S3 spot is faint. Significant increase in S3 color % indicates addn of other grape juice to Concord. Use qual. anthocyanin chromatograms to confirm presence of non-Concord grape juice.

**Malvidin Glucosides (44)—Official First Action****22.099****Principle**

Anthocyanin components are sepd by paper chromatgy, pigments are converted to oxchlorides with HCl vapor, and chromatogram is scanned for presence of malvidin mono- or diglucosides, which are present in minimal concns in Concord grape juice.

**22.100****Reagent**

*Citric acid soln*.—0.1M (MacIvaine's buffer soln B). Dissolve 45 g citric acid.H<sub>2</sub>O and dil. to 2 L with H<sub>2</sub>O. Titr. 10 mL with 0.1N NaOH, **50.034–50.035**, using phthln. Adjust with H<sub>2</sub>O or citric acid to require 30.00 mL 0.1N NaOH in repeat titrn.

**22.101****Apparatus**

(a) *Densitometer*.—Beckman Analytrol Model RB, 550 nm interference filter, or equiv.

(b) *Spectrophotometer*.—Beckman Model B (replaced by model 25), or equiv.

(c) *Melting point capillary tubes*.—1.5–2.0 × 100 mm. Heat and draw out to form application tubes, 1 mm id, open at both ends, and drawn out to ca ½ diam. at one end. Diam. should be such that streak 3 mm wide is deposited.

**22.102****Preparation of Sample**

Mix 5 mL grape juice sample with 5 mL MeOH. Filter thru glass wool.

Det. streaking vol. so amt of pigment in each streak is comparable. Mix sep. 1 mL Concord grape juice std and 1 mL of each sample filtrate with 25 mL citric acid buffer. Det. *A* at 525 nm with spectrophtr.

Calc. mL of filtrate to be streaked = (*A* Concord grape juice std × 0.6 mL)/*A* sample.

0.6 mL Concord grape juice std with *A* = 0.54 gives optimum sepn and color intensity of bands.

Acidify filtrates with 4 drops HCl/5 mL filtrate. Transfer samples to small capped vials to prevent evapn of MeOH.

**22.103****Chromatography**

Draw line 4 cm from bottom of paper, 46 × 57 cm, Whatman 3MM, or equiv., along length of paper to locate five 8 cm streaks. Apply filtrates 8–12 times with application tubes to form 8 cm streaks, 3 mm wide. Let dry between applications. Apply one streak of Concord grape juice std and others of samples. Dry thoroly and acidify by exposing both sides of paper to HCl vapor.

Form streaked paper lengthwise into cylinder and staple both ends, making sure edges of paper do not touch. Fasten 2–3 addnl staples by hand thru holes made with needle.

Add 250 mL H<sub>2</sub>O to cylindrical chromatgy jar, Pyrex or equiv.,

10 1/4" diam., 18" high. Carefully lower paper cylinder into jar (cylinder should not touch sides of jar), cover jar with plastic bag, 12 x 6 x 24", Kordite Turkey Bag, or equiv., and seal bag with masking tape. Remove bag when H<sub>2</sub>O has risen to top of cylinder. Fold filter paper (46 x 57 cm Whatman 3 MM, or equiv.) lengthwise, cut semi-circle at folded edge with diam. ca that of cylindrical chromatogram, open, and place as collar around paper cylinder, resting on top edge of jar. Place cardboard over exposed top edge of cylinder which is just above top of jar and continue developing 10 hr. Pigments should be resolved into well-defined bands. Air dry at room temp. Expose both sides of chromatogram to HCl vapor to convert pigments to red oxchlorides.

**22.104****Determination**

Cut 4 cm strip from center of each streak, mark origin and point 25 cm from origin, and use second mark to position strip in densitometer with 550 nm filter. Obtain densitometer traces and compare std with samples.

Pigments sep. by classes. Sequence of classes from origin is: acylated monoglucosides, monoglucosides, acylated diglucosides, diglucosides, sugars, and more H<sub>2</sub>O-sol. compds. Within classes from origin are: delphinidin, petunidin, cyanidin, peonidin, and malvidin. Malvidin compds, very intense purple or violet, travel at front edge of each class.

Concord grape juice contains min. concns of malvidin mono- and diglucosides while California red grape concs and Italian grape juice color (Enocianina) contain relatively high concns of malvidin mono- or diglucoside. Comparison of malvidin peak of Concord control with malvidin peak of sample will indicate presence of malvidin-contg products (JAOAC 50, 299(1967); *J. Agr. Food Chem.* 11, 263(1963)).

**LEMON JUICE (45)—OFFICIAL FIRST ACTION****22.105 Preparation of Sample**

Mix ca 5–6 g Celite analytical filter aid with 175 mL lemon juice (ca 80–100 milliequiv. acid/100 mL juice). Filter with suction (if not completely clear, refilter thru fresh Celite pad) and store in g-s flask.

**22.106 Total Amino Acids**

Pipet 25 mL prepd sample into 150 mL beaker. (If sample is suspected of contg SO<sub>2</sub>, boil exactly 1 min and cool.) Add NaOH (1+1) dropwise to pH 6–7. Titr. potentiometrically with 0.1*N* NaOH to pH 8.4. Add 10 mL neutzd 37% HCHO (titrd potentiometrically with 0.1*N* NaOH to pH 8.4 ≤ 1 hr before use) and titr. resulting acidity back to pH 8.4 with 0.1*N* NaOH. Total amino acids (milliequiv./100 mL juice) = 0.4 x mL 0.1*N* NaOH for second titrn.

**22.107 Total Polyphenolics**

(a) *Calibration of spectrophotometer.*—Accurately weigh two 1.4–1.5 g portions KNO<sub>3</sub>. Transfer to 250 mL vol. flasks, dissolve in H<sub>2</sub>O, and dil. to vol. Zero instrument at 302 nm and measure *A* of each soln in 1 cm cell. Calc. std *A* for each soln, *A'* = *a* x molarity KNO<sub>3</sub> = (6.99 x g KNO<sub>3</sub>)/(101.11 x 0.25) = 0.2765 x g KNO<sub>3</sub>. Divide av. *A'* by av. measured *A* at 302 nm to obtain correction factor.

(b) *Determination.*—Pipet 0.5 mL prepd sample into 10 mL vol. flask, and dil. to vol. with alcohol. Transfer to centr. tube, cover with Al foil to prevent evapn, and centr. Measure UV spectrum of supernate with recording spectrophtr from 300 to 400 nm or with manual spectrophtr at 2 nm intervals from 325

to 335 nm. Multiply *A* of 325–335 nm peak by correction factor, (a), and report as *A* of total polyphenolics.

***L*-Malic Acid (46)****22.108****Standard Rotation for *L*-Malic Acid**

Accurately weigh ca 15, 25, and 35 mg *L*-malic acid (Calbiochem) into 25 mL vol. flasks. Add ca 0.4 g citric acid to each flask. Dissolve in 5 mL H<sub>2</sub>O, add 1 drop phthln, and neutze with NaOH (1+1). Add HOAc until phthln color disappears, then 2 drops excess. Dil. to vol. with H<sub>2</sub>O. Measure initial optical rotation ( $\alpha_1$ ) of each std soln. (Exercise great care in measuring optical rotation, since small uncertainty in measurement will cause large error in final result.) Sat. 10 mL of each std soln with 1.3 g uranyl acetate.2H<sub>2</sub>O. Keep in dark 30 min with occasional shaking. (Exposure of uranyl complex to strong light causes it to become insol.; therefore conduct operations in semidarkness.) Filter off excess uranyl acetate and measure optical rotation ( $\alpha_u$ ) within 5 min after filtering. Calc. std rotation (*R*<sub>std</sub>) for each soln as follows:

$$C_{\text{malic}} = (\text{mg malic acid}/67.04) \times 4 \\ = \text{milliequiv. malic acid}/100 \text{ mL}$$

$$\Delta\alpha = \alpha_1 - \alpha_u$$

$$R_{\text{std}} = C_{\text{malic}}/\Delta\alpha$$

Use av. std rotation for subsequent calcs.

**22.109****Determination**

In graduate mix 15 mL sample, 22.105, with 45 mL alcohol and let stand 10 min. Centr. pectin ppt. Evap. alc. juice to thick sirup (ca 1–2 mL) in rotary vac. evaporator (≤50°). Add 13–14 mL H<sub>2</sub>O to sirup and mix thoroly. Pipet 2 mL pectin-free sample into 100 mL beaker, and add 25 mL H<sub>2</sub>O. Titr. potentiometrically to pH 8.4 with stdzd 0.1*N* NaOH. Acidity (milliequiv./100 mL pectin-free sample) = 5 x (mL alkali). Pipet 10 mL pectin-free sample into 25 mL vol. flask, add 1 drop phthln, and proceed as in detn of std rotation. *L*-Malic acid concn in dild, neutzd sample, [MA]<sub>D</sub> = *R*<sub>std</sub> x ( $\alpha_1 - \alpha_u$ ). Calc. citric acid:malic acid ratio by dividing 0.4 times acidity of pectin-free sample by [MA]<sub>D</sub>.

**22.110 Recoverable Oil—Official Final Action**

See 22.090–22.093.

## 23. Gelatin, Dessert Preparations, and Mixes

### GELATIN

#### 23.001 Preparation of Sample—Procedure

Mix ground gelatin thoroly. Break sheet gelatin into small pieces by hand. Further comminution is unnecessary in either case.

#### 23.002 Moisture—Official Final Action

Proceed as in 14.003, using 2 g sample prep'd as in 23.001.

#### 23.003 Ash—Official Final Action

See 31.012 or 31.013.

### Total Phosphorus

#### Gravimetric Quinolinium Molybdophosphate Method (1)—Official Final Action

#### 23.004

#### Reagents

(a) *Magnesium oxide-magnesium nitrate slurry*.— See 42.005(b).

(b) *Citric-molybdic acid reagent*.—See 2.026(a).

(c) *Quinoline soln.*—See 2.026(b).

#### 23.005

#### Determination

Weigh ca 3 g sample into Pt dish and mix with 10 mL  $\text{MgO-Mg(NO}_3)_2$  slurry, (a). Evap. mixt. to dryness under IR lamp or on steam bath. Ash 1 hr at 500°.

Moisten cooled ash with  $\text{H}_2\text{O}$ , partially cover dish with watch glass, and cautiously add 10 mL  $\text{HCl}$  (1+1). Heat sample 30 min on steam bath with occasional stirring. Filter into 500 mL erlenmeyer thru S&S white ribbon paper, or equiv. Wash dish and residue on filter with hot  $\text{H}_2\text{O}$  until filtrate vol. is ca 100 mL. Det. P as in 2.028(a). Report as %  $\text{P}_2\text{O}_5$ .

#### 23.006 Nitrogen—Official Final Action

Proceed as in 2.057, using 1 g sample. To convert to ash-free, anhyd. gelatin multiply by factor 5.55 (USDA Circ. 183, August 1931).

#### 23.007 Jelly Strength (2)—Official Final Action

(Caution: Check shot hopper on Bloom Gelometer to assure it is grounded electrically.)

Pipet 105 mL  $\text{H}_2\text{O}$  at 10–15° into std Bloom bottle, add 7.5 g sample, and stir. Let stand 1 hr and then bring to 62° in 15 min by placing in  $\text{H}_2\text{O}$  bath regulated at 65° (sample may be swirled several times to aid soln). Finally mix by inversion, let stand 15 min, and place in  $\text{H}_2\text{O}$  bath at 10±0.1°. Chill 17 hr. Det. jelly strength in Bloom Gelometer (Ind. Eng. Chem., Anal. Ed. 2, 348(1930)), adjusted for 4 mm depression and to deliver 200±5 g shot/5 sec, using 0.5" plunger, Fig. 23.01.

### GELATIN DESSERT POWDERS

#### 23.008 Preparation of Sample—Procedure

Sift sample thru No. 30 sieve onto large sheet of paper, rubbing material thru sieve and tapping vigorously, if necessary. Sift sample 2 more times, mixing thoroly each time. To avoid absorption of moisture, work as rapidly as possible, and store sample in air-tight container.

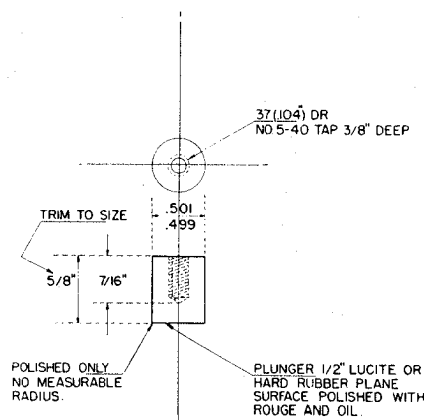

FIG. 23.01—0.5 Inch Bloom Gelometer plunger

#### 23.009 Moisture—Official Final Action

Proceed as in 31.005, using 2 g sample prep'd as in 23.008.

#### 23.010 Ash—Official Final Action

See 31.012 or 31.013.

#### 23.011 Nitrogen—Official Final Action

See 23.006.

#### 23.012 Total Acidity—Official Final Action

Dissolve 20 g sample in 2 L recently boiled  $\text{H}_2\text{O}$ . Titr. 100 mL with 0.1N  $\text{NaOH}$ , using 0.3 mL phthln. Report as % by wt citric acid.

#### 23.013 Jelly Strength—Official Final Action

(Caution: Check shot hopper on Bloom Gelometer to assure it is grounded electrically.)

To 20 g sample in std Bloom bottle, add from pipet, with stirring, 100 mL  $\text{H}_2\text{O}$  at 10–15°. Let stand 15 min and then bring to 62° in 15 min in  $\text{H}_2\text{O}$  bath regulated at 65° (sample may be swirled several times to aid soln). Mix by inversion, let stand 15 min, place in  $\text{H}_2\text{O}$  bath controlled at 10±0.1°, and let stand 17 hr. Det. jelly strength in Bloom Gelometer (Ind. Eng. Chem., Anal. Ed. 2, 348(1930)), adjusted for 4 mm depression and to deliver 200±5 g shot/5 sec, using 1.0" plunger, Fig. 23.02, and light wt shot receiver (paper or plastic).

### Sucrose (3)—Official Final Action

#### 23.014

#### Reagents

(a) *Tannin soln.*—Dissolve 5 g tannin in 100 mL cold  $\text{H}_2\text{O}$ .

(b) *Lead acetate soln.*—Dissolve 100 g  $\text{Pb(OAc)}_2 \cdot 3\text{H}_2\text{O}$  in 200 mL  $\text{H}_2\text{O}$ . (This makes 30° Bé. soln.)

#### 23.015

#### Determination

Place 13 g sample in 300 or 400 mL beaker, add 2 g  $\text{CaCO}_3$  and 2 g Filter-Cel, and mix well with glass rod. Add 175 mL boiling  $\text{H}_2\text{O}$ , creaming mixt. with little of the  $\text{H}_2\text{O}$  at first. Stir thoroly and let stand few min to ensure soln. Cool under cold

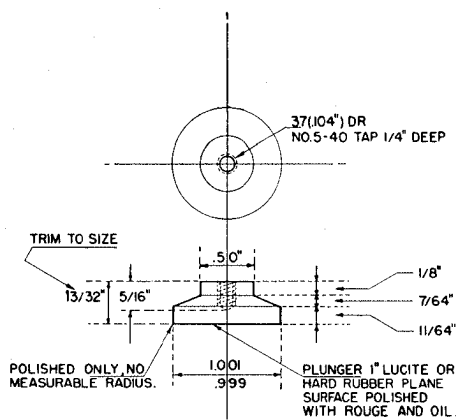

FIG. 23.02—1.0 Inch Bloom Gelometer plunger

H<sub>2</sub>O to 30°, slowly add 25 mL tannin soln with stirring, and let stand 5 min. (This vol. tannin soln is enough for most powders; if 30 mL is required, use 170 mL H<sub>2</sub>O instead of 175 mL.) Slowly add 10 mL Pb(OAc)<sub>2</sub> soln with stirring, and filter on 18.5 cm Whatman No. 2 paper. (Total vol. liq. used in each case is 210 mL, which yields 200 mL after evapn and concn. If pptn has been conducted properly, soln will filter readily and filtrate will be clear.) Read optical rotation of this soln in 200 mm tube at 20°.

If sample contains reducing sugar, delead with K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, add Filter-Cel, and filter. Invert by placing 50 mL filtrate in 100 mL vol. flask with 5 mL HCl and letting stand overnight. After inversion, neutze with concd NaOH soln, using phthln. Discharge color of indicator with 0.1*N* HCl. Cool to 20°, dil. to vol., and read optical rotation in 200 mm tube. Use following Clerget formula modified for % sucrose in gelatin dessert powders:

$$S = \frac{100(4P - 8I)}{142.66 + 0.0676(m - 13) - t/2'}$$

where *S* = % sucrose; *P* = direct reading; *I* = invert reading; *t* = temp. at which readings are made (20°); and *m* = g total solids from original sample/100 mL invert soln (3.25 g). Simplified:

$$S = 100(4P - 8I)/132.$$

### 23.016 Glucose—Official Final Action

Det. polarization due to glucose (*D*) by subtracting % sucrose (*S*) as found in 23.015 from direct reading of polariscope in circular degrees (*P*) multiplied by 4:  $D = 4P - S$ .

$$\% \text{ Glucose} = D \times 66.5/52.5 = 1.267D,$$

where *D* = polarization due to glucose; 66.5 = specific rotation of sucrose; and 52.5 = specific rotation of glucose.

## STARCH DESSERT POWDERS

### 23.017 Preparation of Sample—Procedure

See 23.008.

### 23.018 Moisture—Official Final Action

Proceed as in 31.005 or 31.006, using 2 g prepd sample, 23.008.

### 23.019 Ash—Official Final Action

See 31.012 or 31.013.

### 23.020 Nitrogen—Official Final Action

Proceed as in 2.057, using 1 g sample. To convert to protein, multiply by factor 6.25.

### 23.021 Sucrose and Glucose—Official Final Action

See 23.015 and 23.016.

### 23.022 Starch—Official Final Action

- (a) By direct acid hydrolysis.—See 8.019.
- (b) Polarimetric method.—See 14.032.

## SELECTED REFERENCES

## 24. Meat and Meat Products

### MEAT

#### 24.001 Preparation of Sample—Procedure

To prevent H<sub>2</sub>O loss during prepn and subsequent handling, do not use small samples. Keep ground material in glass or similar containers with air- and H<sub>2</sub>O-tight covers. Prep. samples for analysis as follows:

(a) *Fresh meats, dried meats, cured meats, smoked meats, etc.*—Sep. as completely as possible from any bone; pass rapidly 3 times thru food chopper with plate openings  $\leq \frac{1}{8}$ " (3 mm), mixing thoroly after each grinding; and begin all detns promptly. If any delay occurs, chill sample to inhibit decomposition.

(b) *Canned meats.*—Pass entire contents of can thru food chopper, as in (a).

(c) *Sausages.*—Remove from casings and pass thru food chopper, as in (a).

Dry portions of samples of (a), (b), and (c) not needed for immediate analysis, either *in vacuo*  $<60^\circ$  or by evapg on steam bath 2 or 3 times with alcohol. Ext fat from dried product with pet ether (bp  $<60^\circ$ ) and let pet ether evap. spontaneously, finally expelling last traces by heating short time on steam bath. Do not heat sample or sepd fat longer than necessary because of tendency to decompose. Reserve fat in cool place for examination as in Chap. 28, and complete examination before it becomes rancid.

### Moisture

#### 24.002 Drying in Vacuo at 95–100°—Official Final Action

Proceed as in 7.003. (Not suitable for high fat products such as pork sausage.)

#### 24.003 Air Drying (1)—Official First Action

(a) With lids removed, dry sample contg ca 2 g dry material 16–18 hr at 100–102° in air oven (mech. convection preferred). Use covered Al dish  $\geq 50$  mm diam. and  $\leq 40$  mm deep. Cool in desiccator and weigh. Report loss in wt as moisture.

(b) With lids removed, dry sample contg ca 2 g dry material to const wt (2–4 hr depending on product) in mech. convection oven or in gravity oven with single shelf at ca 125°. Use covered Al dish  $\geq 50$  mm diam. and  $\leq 40$  mm deep. Avoid excessive drying. Cover, cool in desiccator, and weigh. Report loss in wt as moisture. (Dried sample is not satisfactory for subsequent fat detn.)

#### 24.004 Added Water in Sausage (2)—Procedure

$$\text{Per cent H}_2\text{O added} = (W - 4P)/(1 - 0.01W + 0.04P);$$

where  $W$  = % H<sub>2</sub>O, and  $P$  (% protein) =  $6.25 \times \% \text{ N}$  (corrected if necessary for protein in added substances such as nonfat dry milk, cereal, soybean flour).

#### 24.005 Crude Fat or Ether Extract—Official Final Action

(a) Weigh 3–4 g sample by difference into thimble contg small amt of sand. Mix with glass rod, place thimble and rod in 50 mL beaker, and dry in oven 6 hr at 100–102° or 1.5 hr at 125°. Proceed as in 7.056. Pet ether, 10.132, may be used instead of anhyd. ether, if desired.

(b) Weigh 3–4 g sample by difference into small disposable Al dish, add sand, and mix, spreading mixt. on bottom of dish with glass or Al paddle. Dry with paddle as in (a). Roll edges of dish and insert with paddle into thimble. Proceed as in 7.056.

Pet ether, 10.132, may be used in place of anhyd. ether, if desired.

### Rapid Method (3)—Official Final Action

#### 24.006

#### Principle

Fat is extd from sample with C<sub>2</sub>Cl<sub>4</sub> in motor-driven, orbital shaker in presence of drying agent to absorb moisture. Ext is filtered and sp gr of filtrate is measured at 37° by mag. driven hydrometer. Digital reading is converted into fat content, using precalibrated chart.

#### 24.007

#### Apparatus and Reagents

(a) *Foss-let fat analyzer.*—Includes orbital shaker, sp gr read-out unit, solv. dispenser, ref. std oil (sp gr at 23° = 0.915; for periodic check of potentiometer calibration), stainless steel cup with cover and 8 mm bore brass hammer, pressure filtration device, and conversion chart (Foss America, Inc., PO Box 504, Rt 82, Fishkill, NY 12524).

(b) *Drying agent.*—Plaster of Paris (available locally thru paint, hardware, or building supply dealers), 8 mesh Drierite, or anhyd. CaSO<sub>4</sub>.

(c) *Tetrachloroethylene.*—Tech. grade C<sub>2</sub>Cl<sub>4</sub> (distributed locally thru dry cleaning suppliers or Fisher Scientific Co., No. C-182).

#### 24.008

#### Determination

Prep. samples as in 24.001. Check calibration of Foss-let potentiometer daily by using C<sub>2</sub>Cl<sub>4</sub> alone to set zero point and mixt. of 22.5 g ref. std oil and 120 mL C<sub>2</sub>Cl<sub>4</sub> (sp gr of mixt. at 37° = 1.4763) to set 50% fat point at 850.0.

Using either top-load or triple-beam balance with 0.1 g sensitivity, tare Foss-let cup after setting brass hammer on its spindle. To analyze products contg  $\leq 60\%$  fat, weigh 45.0 g sample into cup; for products contg  $>60\%$  fat, weigh 22.5 g. Add ca 80 g Plaster of Paris (or ca 60 g anhyd. CaSO<sub>4</sub>). Dispense 120 mL C<sub>2</sub>Cl<sub>4</sub> into cup. Press cover onto cup and install in orbital shaker. Set shaker timer for 2 min and turn unit on. While extn proceeds, assemble pressure filtration device by placing first 7 cm circle of Whatman No. 50 paper and then 7 cm circle of Whatman No. 1 PS phase sepg paper into perforated base. After 2 min extn, remove cup from shaker, lift cover, and remove brass hammer from cup. Immerse cup in ice-H<sub>2</sub>O bath ca 0.4 min while stirring contents with thermometer to cool contents from 47–52° to ca 40°. Wipe H<sub>2</sub>O from outer surface of cup and pour contents into assembled filter. Place piston at top of filtration device and slowly press ext thru measuring system. Depress drain valve button when ext appears in overflow tube and let chamber drain; then release valve button. Repeat filling and draining 2 more times until 40–50 mL ext has flowed thru, retaining final 10 mL ext in measuring chamber. Remove filtration device, slide viewing lens into position, rotate control of readout potentiometer clockwise until hydrometer rises, and record reading. Establish that ext is at chamber temp. by repeating reading 3–4 times. Average readings and convert into % fat by means of conversion chart. (Multiply chart % fat by 2 if 22.5 g portion of high-fat sample was taken.)

#### 24.009 Ash—Official Final Action

See 31.012 or 31.013.

**Salt (Chlorine as Sodium Chloride)****24.010 Volumetric Method—Official First Action**

Moisten 2.5–3 g sample in 300 mL flask with excess 0.5*N* AgNO<sub>3</sub> soln, **50.027** ( $\geq 5$  mL, depending on NaCl content of sample). Add 15 mL HNO<sub>3</sub> and boil until meat dissolves (10 min usually enough). Add concd aq. KMnO<sub>4</sub> soln in small portions, boiling after each addn until KMnO<sub>4</sub> color disappears and soln becomes colorless or nearly so. Add 25 mL H<sub>2</sub>O and boil 5 min. Cool, dil. to ca 150 mL, add 25 mL ether, and shake. Det. Cl. as in **18.035**.

**Indicating Strip Method (4)—Procedure**

(Applicable to meat, fish, and cheese)

**24.011****Principle**

QUANTAB Chloride Titrator is thin, chem. inert plastic strip, ca 13 × 90 mm, laminated with absorbent paper capillary column impregnated with brown Ag<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>. When strip is placed in aq. soln, fluid rises in column by capillary action and continues to rise as long as Cl soln enters column. Cl in soln reacts with Ag impregnated in column to produce white color change of insol. AgCl. When capillary column is completely satd, moisture-sensitive signal across top of column turns dark blue to indicate completion of titrn. Length of white color change in column is proportional to Cl concn in test soln. Numbered scale is read at tip of white color change and converted to % salt by use of calibration table in package.

**24.012****Apparatus**

QUANTAB Chloride Titrator.—No. 1176 (Ames Co., Div. Miles Laboratories, Inc.); range: 0.3–10% NaCl in food product; precision: ca  $\pm 10\%$ .

**24.013****Preparation of Sample**

- (a) *Meat*.—See **24.001**.
- (b) *Fish*.—See **18.012**.
- (c) *Cheese*.—See **16.232**.

**24.014****Determination**

Follow directions on package insert. Place 10 g prepd sample in suitable container, add 90 mL hot H<sub>2</sub>O, and stir thoroly to ext

NaCl. (If meat coagulates on adding hot H<sub>2</sub>O, take new sample, add H<sub>2</sub>O at room temp., heat to bp, cool, and proceed.) Cool. Place filter paper folded into cone-shaped cup directly into ext. Place QUANTAB into filtrate collected in bottom of cup and let reaction go to completion. After test signal is completely blue, read Titrator and convert reading to % NaCl with calibration table. Multiply by diln factor of 10.

**Total Phosphorus****24.015 Method I—Official Final Action**

Destroy org. matter as in **2.020(c)** or **(d)**, and proceed as in **7.119** or **8.033**.

**24.016 Method II (5)—Official First Action**

Weigh, to nearest mg,  $2.5 \pm 0.1$  g sample, prepd as in **24.001**, into ashing dish (Pt, Vycor, or other suitable material) and dry 30 min at 125° in forced-draft oven. Ash in furnace at 550° to whiteness or near whiteness. Cool, add 25 mL HNO<sub>3</sub> (1+4), and heat on steam bath ca 30 min. Quant. filter into 400 mL beaker, using H<sub>2</sub>O in transfer. Adjust vol. to ca 100 mL and proceed as in **2.028(b)**.

**Automated Method (6)—Official First Action****24.017****Principle**

Phosphate and Mo<sup>+6</sup> react in acid soln to produce 12-molybdophosphoric acid, which is reduced with 1-amino-2-naphthol-4-sulfonic acid to phosphomolybdenum blue. Max. A at 660 nm is proportional to amt P present. Method is applicable to 0.05–0.4% P.

**24.018****Apparatus**

(a) *Automatic analyzer*.—AutoAnalyzer with following modules (Technicon Instruments Corp.): Sampler II; proportioning pump I; continuous digester; proportioning pump II; current stabilizer; constant temp. bath equipped with variable temp. regulator (set at 70°); colorimeter with 15 mm tubular flowcell, 660 nm filters, and No. 9 aperture; voltage stabilizer; recorder with transmittance paper; vac. pump; 2 manifolds (Figs. **24.01** and **24.02**); and 8.5 mL sample cups.

(b) *Pipet*.—Automatic zeroing, 50 mL (Kontes Glass Co., K-763280).

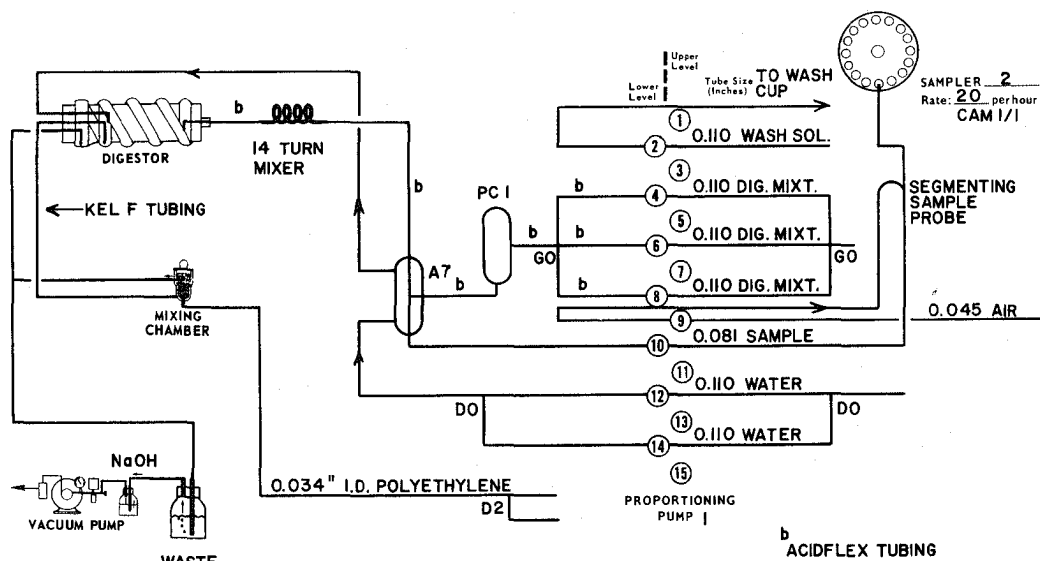

FIG. 24.01—Helix inlet manifold

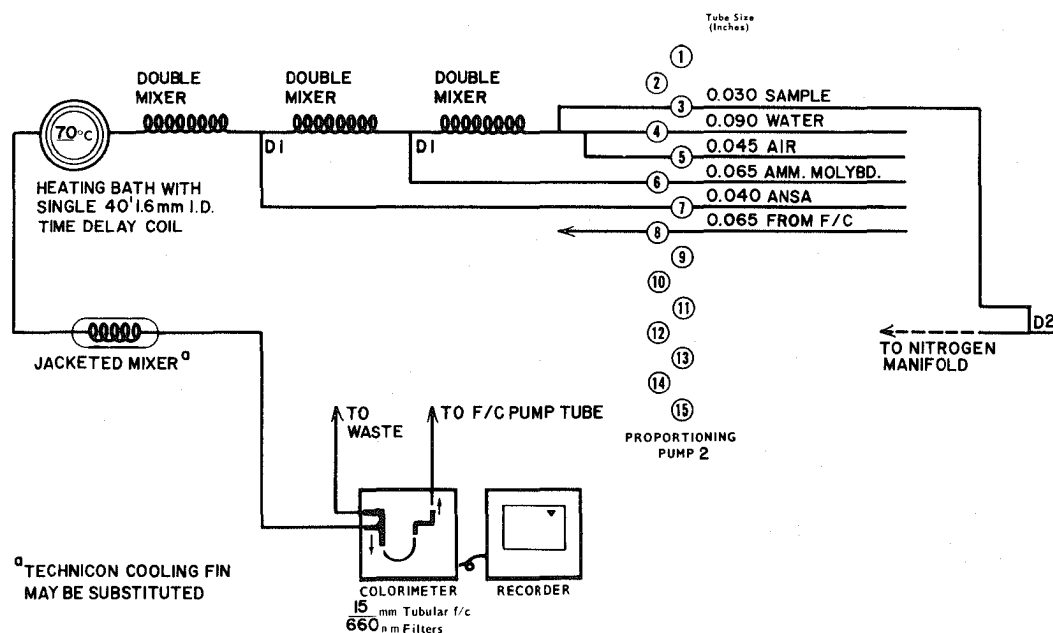

FIG. 24:02—Phosphorus analytical manifold

(c) *Tubing*.—Fluran F-5000, 0.125" id, or Teflon, 0.133" id.

(d) *Pipetting machine*.—Automatic Model 60453, with Model 70327 valve syringe (Sepco, 2201 Aisquith St., Baltimore, MD 21218).

#### 24.019

#### Reagents

(a) *Vanadium pentoxide soln.*—Weigh 40.0 g NaOH pellets and transfer to 1 L vol. flask. Add 500 mL H<sub>2</sub>O, dissolve, and cool. Add 12.5 g V<sub>2</sub>O<sub>5</sub> to flask, dissolve, dil. to vol., and mix.

(b) *Digestion mixture*.—Mix in order: 150 mL V<sub>2</sub>O<sub>5</sub> soln, 90 mL 60–62% HClO<sub>4</sub>, and 3460 mL H<sub>2</sub>SO<sub>4</sub>. (Caution: See 51.028 and 51.030.) Rate of consumption is 495 mL/hr.

(c) *Wash soln.*—H<sub>2</sub>SO<sub>4</sub> (1+1). To 1 L H<sub>2</sub>O in 2 L vol. flask, add 1 L H<sub>2</sub>SO<sub>4</sub> slowly with swirling. (Caution: See 51.030.) Cool to room temp., dil. to vol. with H<sub>2</sub>O, and mix. Rate of consumption is 234 mL/hr.

(d) *1-Amino-2-naphthol-4-sulfonic acid (ANSA)*.—(1) *Soln A*.—Add 2.0 g Na<sub>2</sub>SO<sub>3</sub> and 60 g NaHSO<sub>3</sub> to 320 mL H<sub>2</sub>O in 500 mL vol. flask. Heat to 50° and add 1 g ANSA. Dissolve, cool, dil. to vol., and mix. Store in amber bottle; discard when ppt forms. (2) *Soln B*.—Dil. 100 mL Soln A to 1 L with H<sub>2</sub>O. Add 0.5 mL Levor IV wetting agent (slurry contg 40% Na nonylbenzene sulfonate, Technicon Instruments Corp.). Store in amber bottle. Refrigerate when not in use. Rate of consumption is 36 mL/hr.

(e) *Ammonium molybdate soln.*—Dissolve 30 g (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O in ca 1 L H<sub>2</sub>O. Dil. to 2 L and mix. Rate of consumption is 96 mL/hr.

(f) *Dilution water*.—(1) Pumped thru A7 fitting (Fig. 24:01). Rate of consumption is 468 mL/hr. (2) Pumped thru P analytical manifold (Fig. 24:02). Rate of consumption is 174 mL/hr.

#### 24.020

#### Preparation of Standards

Weigh 10.9839 g KH<sub>2</sub>PO<sub>4</sub> into 250 mL vol. flask, add H<sub>2</sub>O to dissolve, and dil. to vol. Transfer 5.0, 7.5, 10.0, 15.0, 20.0, 25.0, 30.0, and 40.0 mL to 8 sep. 1 L vol. flasks. Add H<sub>2</sub>O to 500 mL. Place flasks in ice bath and slowly add 500 mL H<sub>2</sub>SO<sub>4</sub> to each. Cool, dil. to vol. with H<sub>2</sub>O, and store in 1 L polyethylene bottles.

Based on 10 g sample, as prepd in 24.021, % P = 0.050, 0.075, 0.100, 0.150, 0.200, 0.250, 0.300, and 0.400.

#### 24.021

#### Preparation of Sample

Accurately weigh 10.00 g sample into 200 mL tall-form beaker. Pipet 53 mL H<sub>2</sub>O into beaker with pipetting machine, (d). Add 1" (2.5 cm) Teflon-coated stirring bar, cover with 60 mm watch glass, and disperse sample, using mag. stirrer. With stirring, add 50 mL H<sub>2</sub>SO<sub>4</sub>, using automatic pipet, (b), and continue stirring until sample is dissolved. Cool to room temp. in cooling bath.

#### 24.022

#### Analytical System

Use std 0.0625" id transmission tubing thruout system unless otherwise specified. Pump sample at 2.5 mL/min and segment with air pumped at 0.8 mL/min. Pump digestion mixt. at 8.28 mL/min thru PC1 fitting and add to sample at A7 fitting. Pass sample stream thru 14-turn mixing coil into inlet of digester helix. Pump diln H<sub>2</sub>O at 7.80 mL/min thru A7 fitting to outlet end of digester helix. Aspirate dild sample into bubble chamber and remove aliquot for analysis at 0.35 mL/min. Dil. aliquot with H<sub>2</sub>O pumped at 2.90 mL/min and segment with air at 0.80 mL/min. Pass stream thru 28-turn mixer, and add NH<sub>4</sub> molybdate at 1.60 mL/min. Pass stream thru second 28-turn mixer followed by addn of ANSA Soln B pumped at 0.60 mL/min. After final 28-turn mixer, pass stream into 70° heating bath for color development, cool in jacketed mixer, and pass into colorimeter equipped with 660 nm filters and 15 mm tubular flowcell. Measure A at 660 nm. Pump stream from flowcell at 1.60 mL/min.

#### 24.023

#### Start-Up Procedure

Place all reagent lines, except Acidflex, in water; turn on both proportioning pumps and digester power. Turn on vac. pump, setting gage at 12–15 psi. Pump digestion mixt. and all anal. reagents thru their respective lines after detg that system is operating properly. After 5 min, turn on heat switch and adjust

amperage to proper settings. Amperage should be adjusted to give temp. readout in range of 280–400° in first stage and 250–380° in second and third stages. Warm-up time is ca 20 min (older digester units may require longer). Set recorder baseline at 99% *T* or 0.01 *A*.

**24.024****Shut-Down Procedure**

Turn off heat switch and let first stage temp. reach 200°. Remove helix cover and place all reagent lines except digestion mixt. in H<sub>2</sub>O after first stage temp. is <150°. Place digestion mixt. line in empty erlenmeyer and let Acidflex pump tubes "air-wash." Rinse entire system for 15 min. Shut off proportioning pumps and break vac. in liq. waste bottle. Turn off digester power switch and replace helix cover.

**24.025****Determination**

Pour std and prepd samples into 8.5 mL cups and place in Sampler II turntable. Adjust sampling rate to 20/hr, with 1:1 sample-to-wash ratio to provide 1.5 min sampling and 1.5 min wash. Press reset button and activate sampler turntable, thus passing stds and samples into anal. system. Place stop bar in turntable. (Formation of excessive fat deposits in sample line between segmenting sample probe and input manifold can be retarded by passing wash soln thru double mixer wrapped with heating tape and covered with layer of Al foil and layer of asbestos; adjust temp. to 60° with variable transformer connected to heating tape.)

Read % *T* of samples from recorder strip chart and compare with std curves of % *T* against % *P* on 1 cycle, 70 division semilog paper. A strip chart paper may also be used. Include std curve with every 30 samples. (% *P* can be converted to % Na tripolyphosphate, using gravimetric factor 3.96, after % *P* naturally occurring in meat is deducted.) Diln error caused by variation in moisture content of samples does not significantly affect *P* detn. Std curve is linear thru range of stds.

**24.026 Arsenic—Official Final Action**

See 25.014–25.019.

**Nitrogen****24.027 Kjeldahl Method (7)—Official Final Action**

Proceed as in 2.057, using ca 2 g fresh sample and 40 mL H<sub>2</sub>SO<sub>4</sub> for digestion.

**Automated Method I (8)—Official First Action****24.028****Principle**

NH<sub>3</sub> reacts with hypochlorite and phenate ion in alk. soln to produce quinonechloroamine which reacts with addnl phenate ion, producing blue dissociated form of indophenol with max. *A* at 630 nm in alk. soln.

**24.029****Apparatus**

See 24.018(b), (c), and (d), and in addn:

(a) *Automatic analyzer*.—See 24.018(a). N input manifold is same as for P, Fig. 24.01. N anal. manifold is shown in Fig. 24.03.

**24.030****Reagents**

See 24.019(a), (b) (consumption rate, 497 mL/hr), and (c), and in addn:

(a) *Alkaline tartrate soln*.—Dissolve 150 g K Na tartrate.4H<sub>2</sub>O in 1950 mL H<sub>2</sub>O and add 1050 mL 50% NaOH soln. Consumption rate is 174 mL/hr.

(b) *Sodium hypochlorite soln*.—4–6% NaOCl (Fisher Scientific Co.). Consumption rate is 25 mL/hr.

(c) *Alkaline phenol soln*.—Prep. 15*N* NaOH soln by adding 2400 mL 50% NaOH (w/w) to 600 mL H<sub>2</sub>O, cooling, and storing in polyethylene bottle. To 500 mL 15*N* NaOH in vessel cooled by circulating cold H<sub>2</sub>O, slowly add 276 mL 90% liq. phenol. Cool to room temp. and dil. to 1 L. Store in dark in polyethylene bottle. Consumption rate is 48 mL/hr.

(d) *Dilution water*.—(1) *Input manifold*.—Consumption rate is 468 mL/hr. (2) *Analytical manifold*.—Consumption rate is 234 mL/hr.

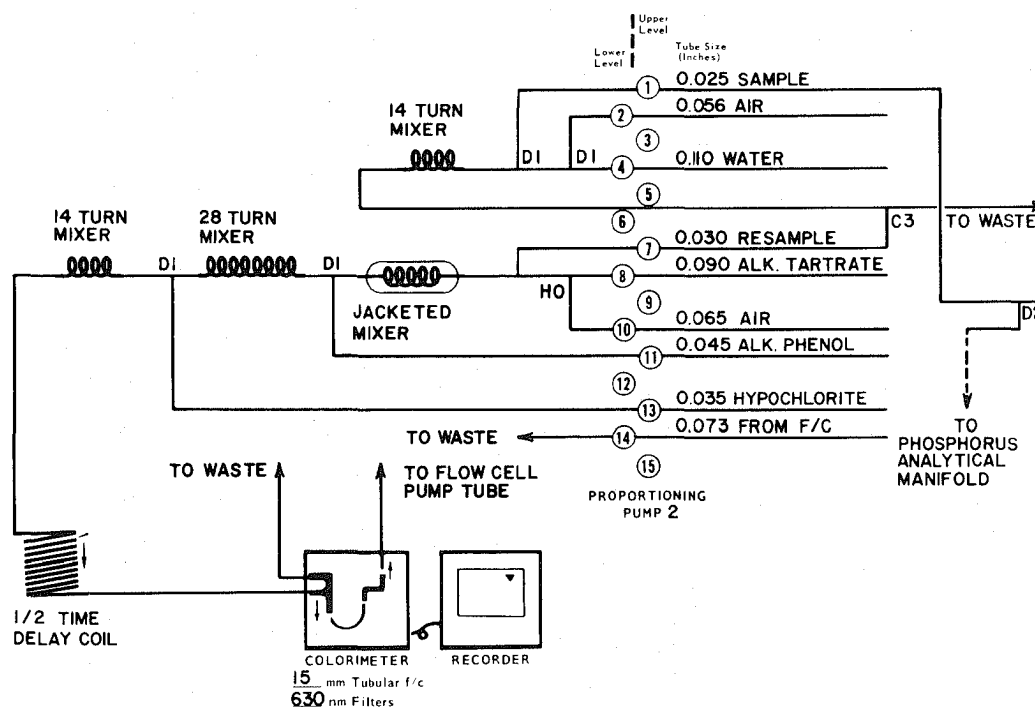

FIG. 24.03—Nitrogen analytical manifold

**24.031****Preparation of Standard**

Grind freeze-dried beef (available from camping supply stores) 4 times in std laboratory mill (Straub Co., Croydon, PA 19020), Model 4-E, or equiv.). Store ground material in freezer to prevent deterioration. Det. Kjeldahl N by **24.027**, using 0.3–0.5 g. Based on N content, prep. stds contg 0.8, 1.2, 1.6, 2.0, 2.4, 2.8, 3.2, 3.6, and 4.0 mg N/mL as follows: Into 9 sep. 1.5 L beakers, transfer weighed amt freeze dried beef. Add 400 mL H<sub>2</sub>O and disperse thoroly, using mag. stirrer. Slowly add, with stirring, 500 mL H<sub>2</sub>SO<sub>4</sub> and continue stirring 15 min. Cool in ice bath until fat solidifies. With aid of stirring rod and funnel, transfer soln thru glass wool pad into 1 L vol. flask. Let warm to room temp., dil. to vol., and mix. Store in polyethylene bottle. Soln is stable  $\geq$  75 days.

**24.032****Preparation of Sample**

Proceed as in **24.021**.

**24.033****Analytical System**

Proceed as in **24.022** thru "... digester helix." Aspirate dild sample into bubble chamber and remove aliquot for analysis at rate of 0.23 mL/min. Dil. aliquot with H<sub>2</sub>O pumped at 3.90 mL/min and segment with air at 1.20 mL/min. Pass stream thru 14 turn mixer and C3 debubbler, and resample at 0.32 mL/min. Add alk. tartrate soln at 2.90 mL/min and air at 1.60 mL/min. Then pass stream thru jacketed mixer, add alk. phenol soln at 0.80 mL/min, and pass thru double mixer. Add NaOCl soln at 0.42 mL/min and pass stream thru 14 turn mixer and ½ time-delay coil for color development. Finally pass stream into colorimeter with 630 nm filter and 15 mm tubular flowcell into waste at 2.00 mL/min.

**24.034****Start-Up Procedure**

Prior to routine use, optimize digester unit as follows: Using 2.0 mg N/mL std in duplicate, vary amperage setting according to following table, and record *A*. Allow 20 min interval after changing setting to stabilize helix temp. before std is analyzed. Use settings giving highest *A*.

Amperage Settings		Amperage Settings	
Stage 1	Stages 2 & 3	Stage 1	Stages 2 & 3
2.50	3.00	4.20	6.40
3.00	4.00	4.50	7.00
3.50	5.00	5.00	8.00
3.80	5.60	5.50	9.00
4.00	6.00		

Set digester helix to rotate at 6.7 rpm, referring to Technicon Manual T-69-123 (1970) for instructions.

**24.035****Shut-Down Procedure**

Proceed as in **24.024**.

**24.036****Determination**

Proceed as in **24.025**. Read *A* of samples from recorder chart and compare with std curve of *A* against mg N/mL. Include std curve with every 30 samples.

As 53 mL H<sub>2</sub>O + 50 mL H<sub>2</sub>SO<sub>4</sub> added to samples gives 95 mL (8 mL contraction), it may be assumed that 10 g samples contg 50% H<sub>2</sub>O give final vol. of 100 mL. However, certain dry products (e.g., pepperoni) or wet products (e.g., corned beef brisket) may contain considerably more or less than 50%, causing an error

by as much as 0.6% protein. Close approximation may be obtained by adding H<sub>2</sub>O content of sample, **24.003(a)** or **(b)**, to 95 mL to obtain final total vol. Using this assumption,

$$\% \text{ N} = [(\% \text{ H}_2\text{O in sample}/10) + 95] \times (\text{mg N/mL}) \times 0.01.$$

$$\% \text{ Protein} = \% \text{ N} \times 6.25.$$

**24.037 Automated Method II (9)—Official First Action**

See **7.021–7.024**.

**Nitrates and Nitrites****Xylenol Method (10)—Official First Action****24.038****Apparatus**

Use simple distn app., including distn bulb. Type of glass condenser utilizing thin, rapidly moving H<sub>2</sub>O film as cooling medium (West type) is recommended.

**24.039****Reagents**

(a) *m*-Xylenol.—2,4-Dimethylphenol. Eastman Kodak Co. No. 1150, or equiv.

(b) Silver-ammonium hydroxide soln.—Dissolve 5 g nitrate-free Ag<sub>2</sub>SO<sub>4</sub> in 60 mL NH<sub>4</sub>OH. Heat to bp, conc. to ca 30 mL, cool, and dil. to 100 mL with H<sub>2</sub>O.

(c) Bromocresol green indicator.—Dissolve 0.1 g bromocresol green in 1.5 mL 0.1*N* NaOH, and dil. to 100 mL with H<sub>2</sub>O.

(d) Nitrate std soln.—Dissolve 0.1805 g recrystd KNO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L, or dil. 17.85 mL 0.1*N* HNO<sub>3</sub> to 1 L; 10 mL contains 0.25 mg nitrate N.

**24.040****Determination**

Mix 5–10 g finely comminuted and thoroly mixed sample with 80 mL warm H<sub>2</sub>O. Break up all lumps and heat on steam bath 1 hr, stirring occasionally. Transfer to 100 mL vol. flask, cool, dil. to vol., and mix. Filter, or let settle, and pipet 40 mL filtrate, or supernate, into 50 mL vol. flask. (No correction for vol. occupied by meat is necessary.) Add 3 drops bromocresol green indicator. Add H<sub>2</sub>SO<sub>4</sub> (1+10) dropwise until color changes to yellow. Oxidize nitrites to nitrates by adding 0.2*N* KMnO<sub>4</sub> soln dropwise with shaking until faint pink remains ca 1 min. Add 1 mL H<sub>2</sub>SO<sub>4</sub> (1+10) and 1 mL phosphotungstic acid soln (20 g/100 mL). Dil. to vol., mix, and filter.

Into 500 mL flask (erlenmeyer is satisfactory) measure aliquot ( $\leq$  20 mL) contg 0.025–0.25 mg nitrate N. (If  $>$  20 mL is required, make slightly alk. and conc. by evapn.) Add enough Ag-NH<sub>4</sub>OH soln to ppt all chlorides and most of excess phosphotungstic acid. (Slight excess of Ag reagent is not harmful; 1 or 2 mL is usually enough.) Without decanting or filtering, add vol. H<sub>2</sub>SO<sub>4</sub> (3+1) ca 3 times vol. liq. in flask. Stopper flask, mix, cool to ca 35°, add 0.05 mL (1–2 drops) of the *m*-xylenol, stopper, shake, and hold 30 min at 30–40°.

(Yellow to brownish yellow color, indicative of nitrates, appears. Bright red ppt, due to incomplete removal of phosphotungstic acid, may also appear. Slight excess of phosphotungstic acid causes no interference but large excess may.)

After nitration is complete, add 150 mL H<sub>2</sub>O, taking care to wash off stopper, and distil 40–50 mL into receiver contg 5 mL NaOH (10 g/L). Quickly remove any nitroxylenol solidifying in condenser by stopping H<sub>2</sub>O flow and letting condenser become warm. Transfer distillate to 100 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and det. nitrate N by comparing reading of color of suitable aliquot with std curve prepd at ca 450 nm.

Prep. color std from 10 mL nitrate std soln, using 0.05 mL *m*-xylenol and 30 mL H<sub>2</sub>SO<sub>4</sub> (3+1), and dilg distillate to 500 mL.

**Nitrites (11)—Official First Action**

(Applicable to cured meats)

**24.041****Reagents and Apparatus**

(a) *NED reagent*.—Dissolve 0.2 g *N*-(1-naphthyl) ethylenediamine·2HCl in 150 mL 15% (v/v) HOAc. Filter, if necessary, and store in g-s brown glass bottle.

(b) *Sulfanilamide reagent*.—Dissolve 0.5 g sulfanilamide in 150 mL 15% HOAc. Filter, if necessary, and store in g-s brown glass bottle.

(c) *Nitrite std solns*.—(1) *Stock soln*.—1000 ppm NaNO<sub>2</sub>. Dissolve 1.000 g NaNO<sub>2</sub> in H<sub>2</sub>O and dil. to 1 L. (2) *Intermediate soln*.—100 ppm NaNO<sub>2</sub>. Dil. 100 mL stock soln to 1 L with H<sub>2</sub>O. (3) *Working soln*.—1 ppm NaNO<sub>2</sub>. Dil. 10 mL intermediate soln to 1 L with H<sub>2</sub>O.

(d) *Filter paper*.—Test for nitrite contamination by analyzing 3–4 sheets, at random, thruout box. Filter ca 40 mL H<sub>2</sub>O thru each sheet. Add 4 mL sulfanilamide reagent, mix, let stand 5 min, add 4 mL NED reagent, mix, and wait 15 min. If any sheets are positive, discard entire box.

**24.042****Determination**

Weigh 5 g finely comminuted and thoroly mixed sample into 50 mL beaker. Add ca 40 mL H<sub>2</sub>O heated to 80°. Mix thoroly with glass rod, taking care to break up all lumps, and transfer to 500 mL vol. flask. Thoroly wash beaker and rod with successive portions of the hot H<sub>2</sub>O, adding all washings to flask. Add enough hot H<sub>2</sub>O to bring vol. to ca 300 mL, transfer flask to steam bath, and let stand 2 hr, shaking occasionally. Cool to room temp., dil. to vol. with H<sub>2</sub>O, and remix. Filter, add 2.5 mL sulfanilamide reagent to aliquot contg 5–50 µg NaNO<sub>2</sub> in 50 mL vol. flask, and mix. After 5 min, add 2.5 mL NED reagent, mix, dil. to vol., mix, and let color develop 15 min. Transfer portion of soln to photometer cell and det. *A* at 540 nm against blank of 45 mL H<sub>2</sub>O, 2.5 mL sulfanilamide reagent, and 2.5 mL NED reagent.

Det. nitrite present by comparison with std curve prepd as follows: Add 10, 20, 30, and 40 mL nitrite working std soln to 50 mL vol. flasks, add 2.5 mL sulfanilamide reagent, mix, and proceed as above, beginning "After 5 min, . . ." Std curve is straight line to 1 ppm NaNO<sub>2</sub> in final soln.

★ **Creatine—Official Final Action** ★**24.043****Preparation of Solution**

Exhaust 7–25 g sample (depending upon H<sub>2</sub>O content) as follows: Weigh into 150 mL beaker, add 5–10 mL cold (15°) NH<sub>3</sub>-free H<sub>2</sub>O, and stir to homogeneous paste. Add 50 mL cold H<sub>2</sub>O, stir at 3 min intervals during 15 min, let stand 2–3 min, and decant liq. thru quant. filter, collecting filtrate in 500 mL vol. flask. Drain beaker, pressing out liq. from meat residue with glass rod. Add 50 mL cold H<sub>2</sub>O to residue in beaker, stir 5 min, let stand 2–3 min, and decant as before. If much meat is transferred to filter, return it to beaker with glass rod. Repeat extns, using two 50 mL portions and four 25 mL portions cold H<sub>2</sub>O. After last extn, transfer entire insol. portion to filter and wash with three 10 mL portions H<sub>2</sub>O, letting material drain thoroly after each addn. Dil. to vol. and mix thoroly.

Measure 150 mL ext into 250 mL beaker and evap. to 40 mL on steam bath, stirring occasionally. Neutze to phthln, using indicator outside the soln. Add 1 mL 0.1*N* HOAc and boil gently 5 min. (Coagulum should sep. at once, leaving clear liq.) Filter

thru quant. paper, wash beaker thoroly 4 times with hot H<sub>2</sub>O, wash coagulum on filter 3 times, and discard coagulum.

**24.044****Determination**

(Caution: See 51.029 and 51.068.)

Evap. filtrate and washings, 24.043, to 5–10 mL, transfer with min. amt hot H<sub>2</sub>O to 50 mL vol. flask, keeping vol. <30 mL, add 10 mL 2*N* HCl, and mix. Hydrolyze 20 min in autoclave at 117–120°, let cool somewhat, and chill under running H<sub>2</sub>O. Partially neutze excess acid by adding 7.5 mL 10% NaOH soln (CO<sub>2</sub>-free), dil. to vol., and mix.

Make preliminary reading after carrying thru reaction on 20 mL with Duboscq colorimeter to det. vol. needed to obtain reading of ca 8 mm. Transfer such vol. to 500 mL vol. flask and add 10 mL 10% NaOH soln and 30 mL *satd* (1.2%) *picric acid soln*. Mix, rotate 30 sec, and let stand exactly 4.5 min. Dil. to vol. at once with H<sub>2</sub>O, shake thoroly, and compare, preferably in Duboscq colorimeter, with std soln prepd by treating with NaOH and picric acid, and dilg to 500 mL as above, 50 mL of soln contg 1.603 g *creatinine Zn chloride* in 1 L 0.1*N* HCl (1 mL = 0.001 g creatinine; g creatinine × 1.16 = g creatine).

**Amino Nitrogen****24.045 ★ Van Slyke Method (12)—Official First Action ★**

Reaction of amino group with HNO<sub>2</sub> to form N which is measured gasometrically. See 24.041–24.042, 12th ed.

**24.046 ★ Sorensen Method (13)—Official First Action ★**

To 20 mL filtrate, 24.043, second par., neutzd to phthln with Ba(OH)<sub>2</sub> or NaOH, or to 20 mL of equiv. ext of meat (sometimes larger vol. may be necessary) add 10 mL freshly prepd *phthln-formol mixt.* (50 mL 40% HCHO soln contg 1 mL 0.05% phthln soln in 50% alcohol, exactly neutzd with 0.2*N* Ba(OH)<sub>2</sub> or NaOH). Tit. mixt. with 0.2*N* Ba(OH)<sub>2</sub> to distinct red, add small but known excess 0.2*N* Ba(OH)<sub>2</sub>, and back-titr. to neutrality with 0.2*N* HCl.

Conduct blank titrn with same reagents, using 20 mL H<sub>2</sub>O in place of soln to be tested. From vol. 0.2*N* Ba(OH)<sub>2</sub> required to neutze mixt., corrected for vol. used in blank titrn, calc. amt amino N present (including NH<sub>3</sub> if this has not been removed).

1 mL 0.2*N* Ba(OH)<sub>2</sub> soln = 2.8 mg amino N.

**24.047 Starchy Flour—Qualitative Tests—Procedure**

(In chopped meat, sausage, deviled meat, etc.)

(a) Treat 5–6 g sample with boiling H<sub>2</sub>O 2–3 min, cool mixt., and test supernate with I soln, 30.029(d). (In interpreting test, note that small amt of starch may be present from use of spices. If strong reaction is given, cereal products are present. This qual. test may be replaced by microscopic examination, which discloses not only presence of added starch but also variety used.)

(b) *Not applicable in presence of cellulosic material other than that from starchy flour and spice*.—To 10 g sample in 100 mL graduated oil tube (ASTM conical form with stem graduated from 0 to 3 mL in 0.1 mL), add 50 mL 8% *alc. KOH soln* and digest on steam bath 1 hr, stirring occasionally. Dil. to 100 mL with alcohol and mix. Let stand 1 hr, gently rotating once or twice during this period to loosen particles on sides of tube. After 1 hr, read vol. of sediment in tube. Vol. >1 mL, if sample contains spices, or >0.5 mL if only spice oils are present, indicates presence of added starchy flour. Vol. <3 mL indicates that <3% flour is present, and vol. >3.5 mL indicates presence of >3.5% flour. (If sample contains dried skim milk or dried corn sirup, before proceeding with test remove lactose or

★ Surplus method—see inside front cover.

maltose by shaking 10 g in 100 mL centr. tube with two 50 mL portions warm H<sub>2</sub>O and centrfg and decanting after each shaking.)

#### 24.048 Soybean Flour—Qualitative Test (14)—Procedure

Mix 10 g finely divided sample in 250 mL beaker with 75 mL 8% alc. KOH soln, and heat on steam bath until all meat is dissolved (30–45 min). Transfer liq. and residue to 100 mL graduated sedimentation tube, dil. to 100 mL with alcohol, and let settle. Decant as completely as possible, and cover residue with ca 50 mL warm H<sub>2</sub>O. Stopper tube and shake vigorously; let stand few min until foam subsides; then transfer to 50 mL centr. tube, and centrfg. Pour off and discard supernate, and add 10 mL HCl to centr. tube. Stopper and shake, or mix contents thoroly with glass rod. Add ca 15 mL 25% alcohol, mix, and centrfg. Decant supernate and examine residue under microscope for characteristic "hour-glass" or I-shaped cells (sometimes called "bearer cells"), preferably with polarized light.

#### 24.049 Preservatives—Official Final Action

See Chap. 20.

#### Qualitative Test for Agar—Official Final Action

##### 24.050

##### Reagents

- (a) *Trichloroacetic acid soln.*—25 g acid in 50 mL H<sub>2</sub>O. (Caution: See 51.082.)
- (b) *Iodine soln.*—Approx. 0.033*N*.
- (c) *Benedict qualitative soln.*—See 16.269(a).

##### 24.051

##### Preparation of Sample

- (a) *Boned chicken or meat.*—Refrigerate overnight to jell broth. With thin-blade spatula, sep. as much jell as possible, and warm on steam bath until completely liquefied.
- (b) *Consommé or broth.*—No prep necessary.

##### 24.052

##### Detection of Gum

Transfer up to 40 mL liquefied jell from meat, or 40 mL consommé, to 100 mL beaker. Add 5 mL trichloroacetic acid soln, stir, and let stand 15–30 min. Transfer to 50 mL conical centr. tube and centrfg. 15–20 min at ca 1200 rpm. Decant clear supernate into 250 mL (8 oz) centr. bottle or nursing bottle, add 4–5 vols alcohol, and let stand until ppt coagulates, or overnight. (No ppt indicates absence of gums.) Centrfg. at 1200 rpm 15–30 min until ppt packs to bottom of centr. bottle. Carefully decant alcohol, taking care not to disturb packed gum ppt. Remove few remaining drops of alcohol by spontaneous drying or by gentle air current. Add 1 drop 0.033*N* I soln. Evanescent violet or black color indicates presence of agar. (Neg. test does not necessarily mean agar is absent.)

Add 3 mL hot H<sub>2</sub>O and warm on steam bath until gum ppt dissolves. Chill gum soln in ice and H<sub>2</sub>O mixt. Thickening, or stiff jell, indicates agar. Warm cooled mixt. on steam bath, transfer to 50 mL beaker, rinse centr. bottle with 3–4 mL H<sub>2</sub>O, and add rinsings to jell soln. Add 1 mL HCl and boil 30 sec. Transfer 1 mL hydrolyzed gum soln to test tube, neutze with 10% NaOH soln, using litmus paper as indicator (ca 2 mL required), remove litmus paper, add 5 mL Benedict soln, and boil cautiously over free flame 30–60 sec. Green, yellow, or brick-colored ppt after spontaneous cooling indicates agar (or other hydrolyzable gum).

#### 24.053 Nonfat Dry Milk (Qualitative Test) (15)—Procedure

(In absence of maltose)

To 10 g comminuted sample in small beaker add 20 mL hot (70–90°) H<sub>2</sub>O. Mix thoroly and filter. Transfer 4 mL filtrate to test tube, add 3–4 drops 5% MeNH<sub>2</sub>.HCl soln, and boil 30 sec. Remove from flame, add 3–5 drops 20% NaOH soln, and shake 10 sec. Soln turns yellow immediately, then slowly changes to carmine if lactose is present, indicating presence of nonfat dry milk.

#### Lactose (16)—Official First Action

##### 24.054

##### Reagents

(a) *Acclimated yeast suspension (for use in presence or absence of maltose).*—Macerate 2 cakes (0.6 oz (17 g) each) bakers yeast and wash with 3 ca 50 mL portions H<sub>2</sub>O, centrfg between washings. Prep. medium contg 1.0 g anhyd. MgSO<sub>4</sub>, 2.0 g NH<sub>4</sub>Cl, 1.0 g anhyd. K<sub>2</sub>HPO<sub>4</sub>, 0.5 g KCl, 0.02 g FeSO<sub>4</sub>.7H<sub>2</sub>O, 0.7 g peptone, and 20.0 g tech. maltose. Dissolve each ingredient in small amt H<sub>2</sub>O and add, in order given, to flask contg ca 500 mL H<sub>2</sub>O. Dil. to 1 L. Warm, filter, bring filtrate to rolling boil, and let cool to room temp. Add washed yeast to 1 L medium and incubate ca 24 hr at 30°, stirring frequently first few hr. Sep. yeast by decanting and centrfg, wash twice with H<sub>2</sub>O, add to 1 L fresh medium, and incubate addnl 24 hr with agitation first few hr. Sep. yeast from medium, wash thoroly ≥4 times with H<sub>2</sub>O, dil. to 100 mL, and refrigerate. Yeast remains active 2–3 weeks. (Yeast may remain active longer if frozen.)

(b) *Washed yeast suspension (for use in absence of maltose).*—Mix 2 cakes bakers yeast to smooth suspension with ca 150 mL H<sub>2</sub>O. Centrfg. 5 min and discard aq. layer. Repeat mixing with H<sub>2</sub>O and centrfg 4 more times, or until supernate after centrfg is practically clear. Again suspend yeast in H<sub>2</sub>O and dil. with H<sub>2</sub>O to 100 mL. Store in refrigerator at ca 4° and shake well before using. Discard after 2 weeks.

(c) *Benedict soln.*—Dissolve 16 g CuSO<sub>4</sub>.5H<sub>2</sub>O in 125–150 mL H<sub>2</sub>O. Dissolve 150 g Na citrate.2H<sub>2</sub>O, 130 g anhyd. Na<sub>2</sub>CO<sub>3</sub>, and 10 g NaHCO<sub>3</sub> in ca 650 mL hot H<sub>2</sub>O. Combine the 2 solns, cool, dil. to 1 L, and filter.

(d) *Lactose std soln.*—1.5 mg anhyd. lactose/mL. Dissolve 1.5789 g lactose.H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(e) *Iodine std soln.*—Mix 5.08 g I with 10.2 g KI, dissolve in small vol. of H<sub>2</sub>O, filter, and dil. to 1 L.

(f) *Sodium thiosulfate std soln.*—Dissolve 9.92 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(g) *Dilute acetic acid.*—Dil. 240 mL HOAc to 1 L with H<sub>2</sub>O.

(h) *Dilute phosphoric acid.*—Dil. 240 mL H<sub>3</sub>PO<sub>4</sub> to 1 L with H<sub>2</sub>O.

(i) *Citric acid-phosphate buffer.*—pH 4.8. Mix solns in proportions of 10.14 mL 0.1*M* citric acid (19.21 g/L) and 9.86 mL 0.2*M* Na<sub>2</sub>HPO<sub>4</sub> (28.4 g anhyd./L), and adjust to pH 4.8, using pH meter. Store in refrigerator and discard if soln becomes turbid.

(j) *Starch soln.*—Rub 2.5 g sol. starch and ca 10 mg HgI<sub>2</sub> in little H<sub>2</sub>O. Dissolve in ca 500 mL boiling H<sub>2</sub>O.

##### 24.055

##### Determination (in Presence of Maltose)

Place 10 g sample in 100 mL vol. sugar flask, add small vol. of H<sub>2</sub>O, and break up sample by agitation. Add ca 50 mL H<sub>2</sub>O and warm on steam bath ca 30 min. Cool to room temp., add 2 mL HCl, and dil. to vol., using bottom of fat layer as meniscus. Add 5.0 mL 20% phosphotungstic acid soln, mix well, let stand few min, and filter thru moist paper. Pipet 40 mL filtrate into 50 mL vol. flask and neutze just to acid side of chlorophenol red or other indicator which shows change at ca pH 4.8. Add 5 mL pH 4.8 buffer soln, dil. to vol., and mix.

Transfer ca 40 mL of this soln to centr. tube to which 5 mL yeast suspension, (a), has been added and from which H<sub>2</sub>O has been sepd. Mix yeast and sample well and incubate 3 hr at 30°, stirring frequently. Centrf. and det. reducing sugars:

Pipet 10 mL clear soln into 300 mL erlenmeyer, add 20 mL Benedict soln, (c), bring to bp in 3–5 min, and boil slowly exactly 3 min. Remove from heat, cool, and add 100 mL H<sub>2</sub>O and 10 mL dil. HOAc, (g), slowly while swirling. Add ca 30% excess std I, (e) (15 mL for ca 1.5% lactose), and agitate to dissolve Cu<sub>2</sub>O. Let flask stand ≥5 min, add 20 mL dil. H<sub>3</sub>PO<sub>4</sub>, (h), and titr. excess I with std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, (f), using starch indicator.

Det. lactose:I ratio by using 10 mL std lactose soln and carrying thru detn as above, beginning "... add 20 mL Benedict soln, ..." Det. I:Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> ratio by using 10 mL H<sub>2</sub>O and carrying thru detn as above, beginning "... add 20 mL Benedict soln, ..."

% Lactose =  $100 KV/W$ , where  $K$  = g lactose/mL I soln,  $V$  = vol. I soln consumed, and  $W$  = g sample in aliquot, considering vol. original sample soln as 100 mL rather than 105 mL, to correct for vol. occupied by meat.

#### 24.056 *Determination (in Absence of Maltose)*

Prep. soln as in 24.055, first par. Place 5 mL washed yeast suspension, (a) or (b), in lipless centr., tube, centr., and drain and discard supernate. Add 40 mL prepd soln to yeast residue in centr. tube, stopper, and shake vigorously to dislodge and suspend yeast. Let stand with occasional shaking 1 hr. Centrf. and det. lactose in clear soln as in 24.055, third par.

#### Starch (17)—Official Final Action

(Not applicable to liver products)

#### 24.057 *Reagents*

(a) *Zinc acetate soln.*—Dissolve 12 g Zn(OAc)<sub>2</sub>·2H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(b) *Potassium ferrocyanide soln.*—Dissolve 6 g K<sub>4</sub>Fe(CN)<sub>6</sub>·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(c) *Copper sulfate soln.*—Dissolve 40.0 g CuSO<sub>4</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(d) *Alkaline tartrate soln.*—Dissolve 200 g Rochelle salt and 150 g NaOH in hot H<sub>2</sub>O, filter, and dil. to 1 L.

(e) *Glucose std soln.*—Dissolve 0.40 g pure glucose in H<sub>2</sub>O and dil. to 200 mL.

(f) *Starch indicator soln.*—Mix 1 g powd sol. starch with 20 mL cold H<sub>2</sub>O. Pour mixt. into 500 mL boiling H<sub>2</sub>O and boil 10 min. Cool, and add few drops CHCl<sub>3</sub>.

(g) *Phosphotungstic acid soln.*—Dissolve 20 g phosphotungstic acid in H<sub>2</sub>O, dil. to 100 mL, and filter.

#### 24.058 *Extraction and Hydrolysis*

Weigh 10 g finely ground and thoroly mixed sample into 250 mL heat-resistant centr. bottle. If fat content is so high as to interfere with subsequent filtering, add 25 mL pet ether, mix thoroly with glass rod, decant, and repeat with 2 addnl 25 mL portions pet ether. Add 100 mL H<sub>2</sub>O, 5 mL freshly prepd Zn(OAc)<sub>2</sub> soln, and 5 mL freshly prepd K<sub>4</sub>Fe(CN)<sub>6</sub> soln. Stopper tightly and let stand 15 min, shaking vigorously several times during this period. Centrf. 15 min at 1500 rpm. Decant supernate into 12.5 cm Whatman No. 3 filter paper in conical funnel, using light suction. To residue in centr. bottle add 25 mL freshly prepd soln contg 1 mL Zn(OAc)<sub>2</sub> plus 1 mL K<sub>4</sub>Fe(CN)<sub>6</sub> solns/200 mL soln. Let stand 10 min, shaking several times during this period; then centr. 10 min at 1500 rpm and decant thru same paper. Repeat last extn with addnl 25 mL Zn(OAc)<sub>2</sub>·K<sub>4</sub>Fe(CN)<sub>6</sub> washing soln. Rinse stopper with H<sub>2</sub>O.

Transfer funnel contg filter paper to centr. bottle. From graduate contg 90 mL hot (ca 70°) 1.5N HCl pour 40 mL into paper to melt adhering fat and to free starch. Poke hole in tip of paper and let acid run into centr. bottle. Wash paper with remainder of acid soln. Suspend bottle in open boiling H<sub>2</sub>O bath so that level of H<sub>2</sub>O in bath is at approx. level of soln within bottle. Do not reflux. Hydrolyze exactly 1.5 hr, keeping H<sub>2</sub>O level of bath at original position, stirring contents of bottle occasionally. Do not transfer paper to centr. bottle, as it will hydrolyze and give high values.

Cool immediately. (If necessary, sample may stand overnight at this point.) Make just alk. to litmus with 20% NaOH (ca 27 mL) and then add 10 mL HCl (1+2). Transfer to 200 mL phosphoric acid flask or 200 mL erlenmeyer marked at 200 mL. Rinse centr. bottle with 15 mL phosphotungstic acid soln, followed by several 10 mL portions H<sub>2</sub>O. Dil. to vol. with fat layer, if any, just above mark. Stopper, shake, let stand ca 30 min, and filter soln thru Whatman No. 1 paper.

#### 24.059 *Determination of Reducing Sugars*

Pipet 20 mL filtrate into 200 mL erlenmeyer. Pipet in 20 mL CuSO<sub>4</sub> soln and 20 mL alk. Rochelle salt soln. Bring to boil within 2 min, swirling occasionally, and continue boiling 1 min. Cool immediately under running H<sub>2</sub>O, transfer to 200 mL vol. flask, dil. to vol. with H<sub>2</sub>O, stopper, and shake.

Pipet 50 mL soln into 200 mL erlenmeyer. Add 25 mL 10% KI and 5 mL H<sub>2</sub>SO<sub>4</sub> (1+3). Titr. with ca 0.025N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, adding 2 mL starch indicator and ca 2.0 g solid KSCN when yellow has almost disappeared. (1 drop Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln should change color from blue to white or faint lilac shade.) Det. blank, using 20 mL H<sub>2</sub>O instead of filtrate, starting at first par. Conduct detn on 20 mL std glucose soln similarly.

$$\% \text{ Starch} = 4 \times 0.9 \times (B - S)/(B - D),$$

where  $B$  = blank titrn in mL;  $S$  = sample titrn in mL;  $D$  = std glucose titrn in mL; 0.9 = factor to convert glucose to starch.

### MEAT EXTRACTS AND SIMILAR PRODUCTS

#### 24.060 *Preparation of Sample—Procedure*

Remove liq. and semiliq. meat exts and similar preps from container, and mix thoroly. (Slight heating expedites mixing of pasty exts.) Carefully remove from bottom of container sediment that forms in many liq. preps and include in sample. If sample is in form of cubes, grind 10–12 cubes in mortar.

#### 24.061 *Moisture—Official Final Action*

(Caution: See 51.015.)

Boil H<sub>2</sub>SO<sub>4</sub> in large Kjeldahl flask 4 hr, close flask with stopper carrying CaCl<sub>2</sub> tube, and cool. (Only needed if glycerol is present.)

Proceed as in 7.003, using ca 2 g powd preps, ca 3 g pasty preps, and 5–10 g liq. exts, according to solid content. Dry powd preps directly without admixture. Dissolve pasty preps in H<sub>2</sub>O and dry with enough ignited sand or pumice stone to absorb soln. When glycerol is present, proceed as follows:

Weigh 2–5 g sample into 5–10 cm diam. metal dish with tight-fit cover. (If subsequent fat detns are to be made, fat extn cones may be used.) Mix substances that dry down to horn-like material with fat-free cotton or other suitable material. Place 200 mL of the fresh H<sub>2</sub>SO<sub>4</sub> in strong, tight vac. desiccator. Place uncovered dish in desiccator and exhaust with vac. pump to pressure ≤10 mm Hg (1.33 kPa).

If pump is not available, place 10 mL ether in small beaker in desiccator and exhaust with H<sub>2</sub>O filter pump. Between pump and desiccator interpose empty bottle next to desiccator and

bottle of H<sub>2</sub>O next to pump. Draw air from desiccator thru the H<sub>2</sub>O and turn desiccator stopcock the instant H<sub>2</sub>O begins to rise in tube leading from empty bottle.

Gently rotate desiccator 4 or 5 times during first 12 hr. After 24 hr, open desiccator, bubbling incoming air thru H<sub>2</sub>SO<sub>4</sub>. Place cover on dish and make first weighing. After weighing, place sample in desiccator contg fresh H<sub>2</sub>SO<sub>4</sub> and exhaust as before. Rotate desiccator several times during interval and weigh again after suitable drying period. Repeat process to const wt.

#### 24.062 Ash—Official Final Action

Proceed as in 31.012 or 31.013. Add enough H<sub>2</sub>O to pasty preps to effect soln and evap. to dryness so as to distribute solids evenly over bottom of dish.

#### 24.063 Total Phosphorus—Official Final Action

Destroy org. matter as in 2.020(c) or (d), and proceed as in 7.119 or 8.033.

#### 24.064 Chlorides—Official Final Action

Dissolve ca 1 g prepd sample, 24.060, in 20 mL 5% Na<sub>2</sub>CO<sub>3</sub> soln and proceed as in 3.071–3.072.

#### 24.065 Total Nitrogen—Official Final Action

See 2.057.

#### 24.066 Creatine—Official Final Action

Dissolve ca 7 g sample in cool (20°) NH<sub>3</sub>-free H<sub>2</sub>O in 150 mL beaker, transfer soln to 250 mL vol. flask, dil. to vol., and mix thoroly. Transfer 20 mL aliquot to 50 mL vol. flask and proceed as in 24.044. From total creatinine value subtract equiv. of preformed creatinine, 24.067, and multiply difference by 1.16 to convert to creatine. Express result as % creatine.

#### 24.067 Creatinine—Official Final Action

(Caution: See 51.029 and 51.068.)

Measure ca 5 mL soln used in 24.066 into 500 mL vol. flask, add 10 mL 10% NaOH soln and 30 mL *satd* (1.2%) *picric acid soln*, mix, and rotate 30 sec. Let stand exactly 4.5 min and dil. to vol. at once with H<sub>2</sub>O. Shake thoroly and read color in

colorimeter after standing. If reading is <7 or >9.5 mm, repeat, calcg vol. of soln necessary to obtain reading of ca 8 mm. Express result as % creatinine, making calcns as in 24.044.

#### 24.068 Preservatives—Official Final Action

See Chap. 20.

#### Sulfur Dioxide

#### 24.069 Qualitative Test

See 20.113.

#### 24.070 Distillation Method

See 20.108.

#### 24.071 Pesticide Residues

See Chap. 29.

## 25. Metals and Other Elements as Residues in Foods

### ANTIMONY

#### American Conference of Governmental Industrial Hygienists-AOAC Method (7)—Official Final Action

##### 25.001

##### Principle

Pentavalent Sb in aq. HCl soln reacts with Rhodamine B to form colored complex extractable with org. solvs. Intensity of extd color is measured spectrophtrically at 565 nm.

##### 25.002

##### Reagents

(H<sub>2</sub>O for aq. reagents should be double distd; final distn from glass.)

(a) *Hydrochloric acid soln.*—6*N*. Dil. concd acid with H<sub>2</sub>O (1+1).

(b) *Dilute phosphoric acid.*—3*N*. Dil. 70 mL H<sub>3</sub>PO<sub>4</sub> (85%) to 1 L with H<sub>2</sub>O.

(c) *Rhodamine B soln.*—0.02% in H<sub>2</sub>O.

(d) *Antimony std solns.*—(1) *Stock soln.*—100 µg Sb/mL. Dissolve 0.1000 g pure Sb in 25 mL H<sub>2</sub>SO<sub>4</sub> with heat; cool, and cautiously dil. to 1 L with H<sub>2</sub>O. (2) *Working soln.*—1 µg/mL. Dil. 2.0 mL stock soln to 200 mL with H<sub>2</sub>O.

(Cool reagents (a), (b), (c), ca 100 mL benzene, and eight 125 mL separators with Teflon stopcocks in refrigerator before use; maintain temp. of 5–10° during extn and color development. Work in subdued light.)

##### 25.003

##### Preparation of Sample

Digest sample as in 25.008. Oxidizing conditions must be maintained.

##### 25.004

##### Determination

(Caution: See 51.019, 51.028, and 51.030.)

Transfer digest or aliquot to 125 mL g-s erlenmeyer, add enough H<sub>2</sub>SO<sub>4</sub> to make total of 5 mL H<sub>2</sub>SO<sub>4</sub>, and evap. to fumes of SO<sub>3</sub>. Cool flask, add 10 drops 70% HClO<sub>4</sub>, and again evap. to white fumes. Cool digest in ice bath ≥30 min; then *slowly* add 5 mL precooled 6*N* HCl by pipet. Let stand in ice bath 15 min; then add 8 mL precooled 3*N* H<sub>3</sub>PO<sub>4</sub>. (Until color is extd into benzene, perform subsequent operations as quickly as possible. Color is stable in benzene several hr.) Immediately add 5 mL precooled Rhodamine B soln, stopper, and shake vigorously. Transfer to precooled 125 mL separator. Pipet 10 mL precooled benzene into separator, shake vigorously 1 min, and discard aq. layer. Transfer benzene layer (red if Sb is present) into test tube and let H<sub>2</sub>O settle. Rinse 1 cm cell with ext, fill cell, and read at 565 nm against benzene blank taken thru entire detn. Refer readings to std curve.

##### 25.005

##### Preparation of Standard Curve

Pipet 0, 2, 4, 6, 8, and 10 mL Sb working std soln into 125 mL g-s erlenmeyers, add 5 mL H<sub>2</sub>SO<sub>4</sub> to each, and proceed as in detn. Plot *A* against µg Sb.

### ARSENIC

##### 25.006

##### Reagents

(a) *Bromine water.*—Half satd. Dil. 75 mL satd Br-H<sub>2</sub>O with equal vol. H<sub>2</sub>O.

(b) *Sodium hypobromite soln.*—Place 50 mL 0.5*N* NaOH in 200 mL vol. flask, and dil. to vol. with half-satd Br-H<sub>2</sub>O, (a).

(c) *Ammonium molybdate-sulfuric acid soln.*—Dissolve 5.000 g (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O in H<sub>2</sub>O and slowly add 42.8 mL H<sub>2</sub>SO<sub>4</sub>. Dil. to 100 mL with H<sub>2</sub>O.

(d) *Arsenious oxide std solns.*—(1) *Stock soln.*—1 mg/mL. Dissolve 1.000 g As<sub>2</sub>O<sub>3</sub> (Caution: See 51.078 and 51.084) in 25 mL 20% NaOH soln and dil. to 1 L. (2) *Intermediate soln.*—10 µg/mL. Dil. 10 mL stock soln to 1 L. (3) *Working soln.*—1 µg/mL. Dil. 100 mL intermediate soln to 1 L.

(e) *Hydrazine sulfate soln.*—1.5% N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O.

(f) *Potassium iodide soln.*—15%. Keep in dark. Discard when soln turns yellow.

(g) *Stannous chloride soln.*—Dissolve 40 g As-free SnCl<sub>2</sub>·2H<sub>2</sub>O in HCl and dil. to 100 mL with HCl.

(h) *Dilute hydrochloric acid soln.*—Dil. 144 mL HCl to 200 mL with H<sub>2</sub>O.

(i) *Lead acetate soln.*—10% Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O in H<sub>2</sub>O.

(j) *Zinc metal.*—30 mesh.

(k) *Sea sand.*—To clean sand ("30 mesh") before use and between detns, mount piece of 3 mm id glass tubing thru rubber stopper in suction flask. Fit piece of rubber or Tygon tubing over top to take bottom of sulfide absorption tube easily and to maintain it upright. Add, in turn, with suction, aqua regia, H<sub>2</sub>O, HNO<sub>3</sub>, and H<sub>2</sub>O to remove all traces of acid (≥5 washings). Wet sand with Pb(OAc)<sub>2</sub> soln and remove excess with suction.

(l) *Silver diethyldithiocarbamate.*—Chill 200 mL 0.1*M* AgNO<sub>3</sub> soln (3.4 g/200 mL) and 200 mL 0.1*M* Na diethyldithiocarbamate soln (4.5 g/200 mL) to 10° or lower. Add carbamate soln to AgNO<sub>3</sub> soln slowly with stirring. Filter thru buchner, wash with chilled H<sub>2</sub>O, and dry under reduced pressure at room temp. Dissolve salt in pyridine (reagent grade) with stirring, chill, and add cold H<sub>2</sub>O slowly until completely pptd. Filter thru buchner, and wash with H<sub>2</sub>O to remove all pyridine. Dry pale yellow crystals under reduced pressure (mp 185–187°; recovery 85–90%). Store in amber bottle in refrigerator. (Second recrystn may be necessary to obtain correct mp.)

(m) *Silver diethyldithiocarbamate soln.*—Dissolve 0.5000 g salt, (l), in colorless pyridine in 100 mL vol. flask, and dil. to vol. with pyridine. Mix, and store in amber bottle. Reagent is stable several months at room temp.

##### 25.007

##### Generators and Absorption Tubes

See Fig. 25.01. Use 2 oz (60 mL) wide-mouth bottles of uniform capacity and design as generators, and fit each by means of perforated stopper with glass tube 1 cm diam. and 6–7 cm long, with addnl constricted end to facilitate connection. Place small wad of glass wool in constricted bottom end of tube and add 3.5–4 g sand, taking care to have same amt in each tube. Moisten sand with 10% Pb(OAc)<sub>2</sub> soln and remove excess by light suction. Clean sand when necessary by treatment (do not remove sand from tube) with HNO<sub>3</sub> followed by H<sub>2</sub>O rinse and suction. Treat with Pb(OAc)<sub>2</sub> soln. If sand has dried thru disuse, clean and remoisten it as directed. Connect tube by means of rubber stopper, glass tube, and rubber sleeve to bent capillary tubing (7 mm od, 2 mm id) tapered at end to slide easily into connecting tube and later into neck of 25 mL vol. flask. Other end of capillary is sealed to Pyrex 19/38 female joint. To transfer contents of trap, attach bulb aspirator to male 19/38 joint and place in top of trap.

FIG. 25:01—Arsenic apparatus

Clean traps between detns without removing beads by flushing with  $\text{H}_2\text{O}$ , followed by  $\text{HNO}_3$ , soaking for 30 min or until  $\text{HNO}_3$  becomes colorless. Remove all traces of acid with  $\text{H}_2\text{O}$ , rinse with acetone, and dry with air current applied by suction to tip of trap.

**25.008****Preparation of Sample**

(Caution: See 51.019, 51.026, and 51.030.)

(For details of convenient churn-type washer that will remove arsenical spray residues from firm fruits or vegetables with an aq.  $\text{NH}_4\text{NO}_3\text{-HNO}_3$  soln, see JAOAC 26, 150(1943). Digest aliquot of "strip" soln and proceed as in (a).)

All digestions can be greatly facilitated by following optional method, JAOAC 47, 629(1964): Proceed as in (a) until mixt. no longer turns brown or darkens. Cool, add 0.5 mL 70%  $\text{HClO}_4$  (Caution: See 51.028), and heat until fuming occurs and digest is clear. Cool, and add 2 addnl 0.5 mL portions  $\text{HClO}_4$ , heating each time as above. Finish digestion with  $\text{H}_2\text{O}$  and satd  $\text{NH}_4$  oxalate as in (a).

Conduct  $\geq 1$  blank detn with samples. Blanks should not show  $> 1 \mu\text{g As.}$ )

(a) *For fresh fruits (apples, pears, or similar products).*—Weigh and peel representative sample (1–5 lb; 0.5–2 kg). At blossom and stem ends cut out all flesh thought to be contaminated with As compds and include with peelings, if desired. Place peelings in 1 or more 800 mL Kjeldahl flasks. (As-free Pyrex glassware and "wet ashing" app. of Duriron are available.) Add 25–50 mL  $\text{HNO}_3$ ; then cautiously add 40 mL  $\text{H}_2\text{SO}_4$  (20 mL if Gutzeit method is used). Place each flask on asbestos mat with 5 cm hole. Warm slightly and discontinue heating if foaming becomes excessive.

When reaction has quieted, heat flask cautiously and rotate occasionally to prevent caking of sample upon glass exposed to flame. Maintain oxidizing conditions in flask at all times during digestion by cautiously adding small amts of  $\text{HNO}_3$  whenever mixt. turns brown or darkens. Continue digestion until org. matter is destroyed and  $\text{SO}_3$  fumes are copiously evolved. (Final soln should be colorless, or at most light straw color.) Cool slightly, and add 75 mL  $\text{H}_2\text{O}$  and 25 mL satd  $\text{NH}_4$  oxalate soln to assist in expelling oxides of N from soln. Evap. again to point where fumes of  $\text{SO}_3$  appear in neck of flask. Cool, and dil. with  $\text{H}_2\text{O}$  to 500 or 1000 mL in vol. flask.

(b) *For dried fruit products.*—Prep. sample by alternately

grinding and mixing 4–5 times in food chopper. Place 35–70 g portions in 800 mL Kjeldahl flasks, and add 10–25 mL  $\text{H}_2\text{O}$ , 25–50 mL  $\text{HNO}_3$ , and 20 mL  $\text{H}_2\text{SO}_4$ . Continue digestion as in (a). Dil. digested soln to 250 mL.

(c) *For small fruits, vegetables, etc.*—Use 70–140 g sample and digest as in (a) or (b).

(d) *For materials other than (a), (b), or (c).*—Digest 5–50 g, according to moisture content and amt of As expected, as in (a) or (b). Dil. to definite vol. detd by As concn expected.

(e) *For products containing stable organic As compounds, products liable to yield incompletely oxidized organic derivatives that inhibit arsine evolution, or products that are difficult to digest.*—Shrimp, tobacco, oils, and some other products require special treatment to complete oxidn of org. As to inorg.  $\text{As}_2\text{O}_3$ , or to destroy org. interferences previous to As detn. For details consult:

Ind. Eng. Chem., Anal. Ed. 5, 58(1933); 6, 280, 327(1934); JAOAC 20, 171(1937); 47, 629(1964).

Dil. As solns obtained by these special methods of prepn to definite vol.

(f) *For ultra-micro quantities of As, very labile forms of As, and vacuum-accelerated Gutzeit reduction system for mercuric bromide spot filtration.*—Consult Ind. Eng. Chem., Anal. Ed. 16, 400(1944).

**25.009****Isolation of Arsenic**

Before making detns, isolate As, when interfering substances are present in digests (e.g., pyridine from tobacco), or when samples contain excessive amts of salts, or  $\text{H}_2\text{SO}_4$  from digestions. Consult first ref. of 25.008(e) for method of isolating As after digestion, or isolate As by  $\text{AsCl}_3$  distn (JAOAC 16, 75, 325(1933); 17, 202(1934) or 36.036, par. 2). Gelatin may be hydrolyzed with  $\text{HCl}$  and As isolated as in first ref. of 25.008(e).

**Molybdenum Blue Method (2)—Official Final Action****25.010****Determination**

Transfer 20 mL aliquots of sample and blank digest solns to generator bottles. Add, swirling after each addn, 10 mL  $\text{H}_2\text{O}$ , 5 mL dil.  $\text{HCl}$ , (h), 5 mL  $\text{KI}$  soln, (f), and 4 drops  $\text{SnCl}_2$  soln, (g). Let stand  $\geq 15$  min.

Place 4 g sea sand over small glass wool wad in sulfide absorption tube and cap with glass wool. Place 3 mm diam. solid glass beads in trap over small glass wool pad until  $\frac{1}{4}$  full and add 3.0 mL  $\text{NaOBr}$  soln, (b). Assemble app. except for generator bottle. Add 4 g  $\text{Zn}$ , (j), to generator bottle, attach immediately, and let react 30 min.

Disconnect trap and transfer contents to 25 mL vol. flask with aspirator assembly. Rinse trap with six 2 mL portions  $\text{H}_2\text{O}$  and aspirate into flask. Add, with swirling, 0.5 mL  $\text{NH}_4$  molybdate- $\text{H}_2\text{SO}_4$  soln, (c), and 1.0 mL  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  soln, (e). Dil. to vol., mix, and let stand 75 min. Mix, and read in spectrophtr or colorimeter at 845 nm against blank prepd similarly. Alternatively, heat vol. flask and contents 10 min at  $50^\circ$  and cool in tap  $\text{H}_2\text{O}$  to room temp. before reading. Det.  $\text{As}_2\text{O}_3$  (or As) in aliquot from std curve.

**25.011****Preparation of Standard Curve**

Place 0.0, 1.0, 2.0, 3.0, 5.0, 6.0 mL std soln contg  $10 \mu\text{g As}_2\text{O}_3/\text{mL}$  in 25 mL vol. flasks. Add 3.0 mL  $\text{NaOBr}$  soln, (b), and  $\text{H}_2\text{O}$  to 15 mL. Add, with swirling, 0.5 mL  $\text{NH}_4$  molybdate- $\text{H}_2\text{SO}_4$  soln, (c), and 1.0 mL  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  soln, (e). Dil. to vol., mix, and let stand 75 min or heat 10 min at  $50^\circ$  as for samples. Mix, and read at 845 nm. Plot  $A$  against  $\mu\text{g As}_2\text{O}_3$  (or As).

**Silver Diethyldithiocarbamate Method (3)**  
**Official Final Action**

**25.012****Determination**

Transfer aliquot of sample digest, **25.008** (usually 2–5 mL), and same vol. blank to generator bottles. Add H<sub>2</sub>O to 35 mL; then add, with swirling, 5 mL HCl, 2 mL KI soln, (f), and 8 drops SnCl<sub>2</sub> soln, (g), and let stand ≥15 min. Evolve AsH<sub>3</sub> as in **25.010**, except add 4.0 mL Ag diethyldithiocarbamate soln, (m), to trap.

Disconnect trap and mix trapping soln by gently drawing back and forth 5 times with aspirator assembly. Transfer soln directly to spectrophtr cell (g-s preferred) and read at 522 nm. Det As<sub>2</sub>O<sub>3</sub> (or As) in aliquot from std curve.

**25.013****Preparation of Standard Curve**

Place 0.0, 1.0, 3.0, 6.0, 10.0, and 15.0 mL std soln contg 1.00 μg As<sub>2</sub>O<sub>3</sub>/mL in generator bottles. Add H<sub>2</sub>O to 35 mL and proceed as in **25.012**. Read at 522 nm and plot A against μg As<sub>2</sub>O<sub>3</sub> (or As).

**Molybdenum Blue Method for Meat and Poultry (4)**  
**Official Final Action**

**25.014****Principle**

Sample is ashed in presence of Mg(NO<sub>3</sub>)<sub>2</sub> at 600°. Ash is dissolved in dil. HCl; Zn is added to generate AsH<sub>3</sub>, which is trapped with I soln in cell. Heteropoly blue compd is developed and read at 840 nm in same cell. Chief source of error is often contamination. Always perform reagent blank and, when possible, std sample.

**25.015****Reagents**

(Glassware should not be subjected to routine washing with soap or detergents, which are often source of As contamination. When soap or detergent is used, clean with aqua regia before use. Rinse delivery tubes by holding in slanted position with crook up and squirting jet of H<sub>2</sub>O up and over inside crook until tube is filled; then rinse outside while tube drains. Repeat rinsing 3 times. Rinse funnels in each direction alternately by filling end that is up and placing funnel on 1-hole rubber stopper in mouth of vac. flask to pull H<sub>2</sub>O thru frit by vac.)

(a) *Tissue solvent*.—CHCl<sub>3</sub> (or benzene)-acetone-absolute alcohol (1+1+2).

(b) *Dilute hydrochloric acid*.—Mix 175 mL HCl and 280 mL H<sub>2</sub>O.

(c) *Potassium iodide soln*.—15%. See **25.006(f)**.

(d) *Stannous chloride soln*.—40% in dil. HCl, (b). Store in contact with metallic Sn.

(e) *Zinc*.—Shot of uniform size and shape, ca 0.5 g each.

(f) *Lead acetate soln*.—Prep. satd aq. Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O soln in dropping bottle. Prep. fresh weekly or when soln becomes cloudy.

(g) *Iodine solns*.—(1) 0.02N.—Dissolve 8 g KI and 2.54 g I in small amt H<sub>2</sub>O and dil. to 1 L with H<sub>2</sub>O. Store in dark bottle. (2) 0.001N.—Dil. 5 mL 0.02N I to 100 mL with H<sub>2</sub>O. Prep. fresh daily.

(h) *Ammonium molybdate soln*.—Dissolve 7.0 g (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O in warm mixt. of 70 mL H<sub>2</sub>SO<sub>4</sub> and 300 mL H<sub>2</sub>O, cool, and dil. to 500 mL with H<sub>2</sub>O.

(i) *Hydrazine sulfate soln*.—Dissolve 0.3 g N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O and dil. to 200 mL.

(j) *Arsenious oxide std solns*.—(1) *Stock soln*.—1 mg As/mL. Dissolve 0.1320 g As<sub>2</sub>O<sub>3</sub> in 50 mL H<sub>2</sub>O contg 0.7 mL 50% NaOH. Neutze with 50% H<sub>2</sub>SO<sub>4</sub> and dil. to 100 mL. (2) *Working solns*.—Dil. sep. 1.0 mL portions stock soln to 100, 200, and 500 mL with H<sub>2</sub>O (10, 5, and 2 μg As/mL, resp.).

(k) *Arsanilic acid std solns*.—(1) *Stock soln*.—1 mg As/mL.

Dissolve 0.2897 g arsanilic acid (based on label assay) in H<sub>2</sub>O and dil. to 100 mL with H<sub>2</sub>O. (2) *Working solns*.—Prep. in same concns as in (j).

**25.016****Apparatus**

(a) *Cell rack*.—Metal rack capable of holding eight 19 × 105 mm cells in 600 mL beaker.

(b) *Distilling apparatus*.—Kingsley-Schaffert As distg app. (Corning Glass Works, No. 33680), consisting of 125 mL flask, funnel trap, and bent dispersion tube.

(c) *Absorbent cotton*.—See **25.022(i)**.

**25.017****Preparation of Sample**

Assure absence of interferences arising from laboratory and reagent contamination. Recoveries thru method of added compds should be ≥90%. Conduct one or more reagent blanks and std samples along with samples.

To obtain representative aliquot of large sample (≥100 g), grind entire sample ≥2 times, using fine plate (grind liver sample only once or blend). Mix thoroly and weigh calcd amt into 50 mL Vycor crucible. Add 4 g Mg(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O/10 g sample and mix, using stainless steel spatula or glass rod, until all Mg(NO<sub>3</sub>)<sub>2</sub> is dissolved. Spread mixt. in even layer around sides of crucible.

For smaller samples (<100 g), weigh known amt or entire sample into homogenizer or blender, add 4 g Mg(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O/10 g sample and enough tissue solv. to aid blending, weigh, and blend 1 min. (*Caution*: Use explosion-proof blender when benzene-acetone-alcohol is used as tissue solv.) Weigh aliquot equiv. to desired amt sample into 50 mL Vycor crucible and carefully evap. excess solv. and H<sub>2</sub>O from tissue on steam bath or in 95° oven.

**25.018****Determination**

Place crucible in cool furnace, gradually increase temp. to 600°, and ash sample at 600° until most visible C is burned. Cool crucible and cool furnace. Dampen ash with H<sub>2</sub>O and add 3 mL HNO<sub>3</sub> (1+4). Place in cooled furnace (100°) and heat gradually to 600°. Hold at 600° ca 1 hr until all HNO<sub>3</sub> fumes are evolved. Repeat dil. HNO<sub>3</sub> treatment if necessary to obtain white ash.

Remove crucibles and let cool. Dampen ash with H<sub>2</sub>O and dissolve in 10 mL dil. HCl, (b), delivered from all-glass hypodermic syringe without needle. Quant. transfer to 125 mL flask, **25.016(b)**, with aid of two 10 mL portions dil. HCl and wash sides of flask with fourth 10 mL portion. (Use same vol. liq. for each sample because vol. of air space above liq. affects efficiency of distn of H and AsH<sub>3</sub>.) Cool to room temp. Add 2.0 mL 15% KI soln and mix thoroly by swirling. Add 1.0 mL 40% SnCl<sub>2</sub> soln and mix thoroly by swirling. Let stand ≥15 min (but <30 min). Place 7.0 mL 0.001N I soln in cell. Place small ball absorbent cotton in top of funnel and dampen with satd Pb(OAc)<sub>2</sub> soln. Lubricate ground glass joint with H<sub>2</sub>O and join delivery tube to funnel firmly. This union must be firm enough to hold together under wt of funnel, flask, and contents. Union must not be so firm as to prevent disassembly. Do not dry parts by heating before use. Teflon sleeves are not satisfactory.

Fill 600 mL beaker with finely crushed ice layered between levels of cell holder. Add ice-H<sub>2</sub>O to ca 2/3 ht of beaker and place cell in holder. (It may be necessary to make path thru ice for cell.) Lubricate lower ground glass joint of funnel with H<sub>2</sub>O, add ca 12.5 g Zn to flask, join flask and funnel firmly, and place delivery tube in cell as quickly as possible. Let distn continue 1 hr (without added heat).

Carefully and slowly remove delivery tube from cell, letting liq. drain as tube is removed. Add 0.5 mL NH<sub>4</sub> molybdate soln

and mix thoroly. Add 0.3 mL  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  soln and mix thoroly. Place cell (in cell holder) in moderately boiling  $\text{H}_2\text{O}$  bath or on medium (not vigorous) steam bath 10 min. Remove from bath, wipe cell dry with soft lintless material, and place in cool, dark place ca 1 hr (to ensure that samples reach same temp. and full color development). Read in precalibrated spectrophtr or colorimeter at 840 nm against  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ . Correct for blanks.

#### 25.019 *Preparation of Standard Curve*

Prepare stds of 10 g As-free liver, 4 g  $\text{Mg}(\text{NO}_3)_2$ , and suitable amts arsanilic acid working solns in definite progression, such as 2, 4, 6, 8, and 10  $\mu\text{g}$  As. Repeat analysis of stds  $\geq 3$  times. Det. mean for each level and prep. curve; or fit line by method of least sqs, in *Definitions of Terms and Explanatory Notes*, Item (24), if desired.

#### 25.020 ★ *Gutzeit Method (5)—Official Final Action* ★

Sample is wet ashed, and As is reduced with Zn to  $\text{AsH}_3$ , which reacts with  $\text{HgBr}_2$ -impregnated paper strips to form a darkened area whose length is proportional to amt As. See 25.006–25.009, 11th ed.

### CADMIUM

#### Dithizone Method (6)—Official Final Action

#### 25.021 *Principle*

Sample is digested with  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ . All reactive metals are extd from soln (after adjustment to pH ca 9) with dithizone- $\text{CHCl}_3$ . Cu, Hg, and most of any Ni or Co present are removed by stripping  $\text{CHCl}_3$  soln with dil. HCl. Aq. layer, adjusted to 5% NaOH, is extd with dithizone- $\text{CCl}_4$ . At this alky, Zn, Pb, and Bi do not ext, whereas Cd dithizonate is relatively stable. Stripping with dil. HCl and development of Cd dithizonate in 5% NaOH are repeated. Cd is finally estd photometrically as dithizonate. Zn constitutes chief interference.

#### 25.022 *Reagents*

(a) *Citrate*.—Diammonium salt or citric acid.

(b) *Chloroform*.—Distil from hot  $\text{H}_2\text{O}$  bath, collecting distillate in absolute alcohol in proportion of 10 mL alcohol to 1 L distillate. Intermittently shake receiver during distn.

(c) *Diphenylthiocarbazone (dithizone), twice purified*.—Purify as in 25.095(e), but make only 3 dil.  $\text{NH}_4\text{OH}$  extns of  $\text{CHCl}_3$  soln. Carry thru, including  $\text{H}_2\text{O}$ -washing steps, and then repeat purification with 3  $\text{NH}_4\text{OH}$  extns, pptn with dil. acid, etc. Instead of heating ext to dryness, evap. spontaneously, and complete drying under vac. in bell jar overnight.

(d) *Carbon tetrachloride*.—(Caution: See 51.011(b) and 51.049.) Reflux vigorously on steam bath 1 hr with  $\frac{1}{20}$  vol. 20% KOH in MeOH. Cool, add  $\text{H}_2\text{O}$ , drain off  $\text{CCl}_4$  layer, and wash  $\geq 3$  times with copious vols of  $\text{H}_2\text{O}$  until alkali-free. Dry over  $\text{CaCl}_2$ , filter, and distil on hot  $\text{H}_2\text{O}$  bath. (Unless reagent is so purified, erratic Cd results may be obtained with some lots of  $\text{CCl}_4$ .)

(e) *Dithizone in carbon tetrachloride*.—20 mg/L  $\text{CCl}_4$ . (d). Prep. daily, as dil. solns of dithizone are unstable. (When many detns are to be made, dithizone reagent may be prepd by diln from 300 mg/L soln. Store concd reagent under 0.1M  $\text{SO}_2$  soln in refrigerator.)

(f) *Dithizone in chloroform*.—1000 mg/L  $\text{CHCl}_3$ , (b), prepd as needed.

(g) *Sodium hydroxide soln*.—28%. Dissolve 28 g NaOH pellets in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(h) *Thymol blue indicator*.—Triturate 0.1 g indicator in agate mortar with 4.3 mL 0.05N NaOH. Dil. to 200 mL in g-s flask with  $\text{H}_2\text{O}$ .

(i) *Absorbent cotton*.—Metal-free. If traces of metal are present, remove by digesting cotton several hr with 0.2N HCl, filtering on buchner, and finally washing with copious vols of redistd  $\text{H}_2\text{O}$  until acid-free.

(j) *Cadmium std solns*.—(1) *Stock soln*.—1 mg/mL. Dissolve 1 g Cd (Fisher Chemical Co., certified 99.9% pure, C-565, or equiv.) in 20–25 mL  $\text{HNO}_3$  (1+9), evap. to dryness, add 5 mL HCl (1+1), evap. to dryness, and then add several mL  $\text{H}_2\text{O}$  and again evap. to dryness. Dil. to 1 L. (2) *Intermediate soln*.—100  $\mu\text{g}$ /mL. Dil. 10 mL stock soln to 100 mL. (3) *Working soln*.—2  $\mu\text{g}$ /mL. Transfer 20 mL intermediate soln to 1 L vol. flask, add 15 mL HCl, and dil. to vol. to give final acidity of ca 0.2N.

#### 25.023 *Preparation of Standard Curve*

Prep. in duplicate 6 stds contg 0, 5, 10, 15, 20, and 25  $\mu\text{g}$  Cd as follows: Add appropriate vols std soln to Squibb-type separators (125 mL size is convenient), adjust to 40 mL with 0.2N HCl, add 10 mL NaOH soln (soln is then 5% with respect to NaOH) and 25 mL dithizone soln, (e), shake vigorously exactly 1 min, let stand exactly 3 min, and filter org. layer thru pledget of absorbent cotton, discarding first 5 mL. Fill absorption cell (1 cm length is convenient) and det. A at 510 nm. Plot std curve or calc. ref. equation by method of least squares, *Definitions of Terms and Explanatory Notes*, Item (24).

#### 25.024 *Preparation of Sample*

Use sample equiv. to 5–10 g of product, calcd to dry basis. (Sample size is of concern only when comparatively large amts of Mg and P are present.) Digest with 10 mL  $\text{H}_2\text{SO}_4$  (1+1) and  $\text{HNO}_3$  as needed. If sample tends to char rather than to oxidize evenly, add 5 or 10 mL addnl  $\text{H}_2\text{SO}_4$ . Continue digestion, adding  $\text{HNO}_3$  as required, until digestion is complete and  $\text{SO}_3$  is evolved. Cool, add 15 mL satd  $\text{NH}_4$  oxalate soln, and again heat to fumes.

Fat in biological materials, such as liver and kidney, may cause bumping and frothing during digestion. If comparatively large samples of such materials are available, make partial digestion with warm  $\text{HNO}_3$  until only fat remains undissolved. Cool, filter free of solid fat, wash residue with  $\text{H}_2\text{O}$ , make combined filtrate to suitable vol., and digest appropriate aliquots as above.

#### 25.025 *Determination*

Dil. digest, 25.024, with 25 mL  $\text{H}_2\text{O}$ , filter free from excessive insol. matter (sulfates or silica) if present, and transfer to separator marked at 125 mL, using addnl 10 mL portions  $\text{H}_2\text{O}$  for rinsing and completing transfer. Add 1–2 g citrate reagent, (a), and 1 mL thymol blue indicator, (h), and adjust to ca pH 8.8 by adding  $\text{NH}_4\text{OH}$  slowly, while cooling intermittently, until soln changes from yellowish green to greenish blue. Dil. to 125 mL mark with  $\text{H}_2\text{O}$ . Ext vigorously with 5 mL portions dithizone soln, (f), until  $\text{CHCl}_3$  layer remains green. Then ext with 3 mL  $\text{CHCl}_3$ .

Transfer all  $\text{CHCl}_3$  exts to second separator previously wetted with 2–3 mL  $\text{CHCl}_3$ . Add 40 mL 0.2N HCl to combined dithizone exts, shake vigorously  $\geq 1$  min, and after layers sep., carefully drain  $\text{CHCl}_3$  phase contg any Cu, Ni, Co, or Hg that may be present, and discard. Remove remaining droplets of dithizone by extg with 1–2 mL  $\text{CCl}_4$ , (d), carefully conducting draining operation so that no acid enters bore or stem of separator, as its presence there would in part decompose Cd dithizonate subsequently formed and extd in next step.

★ Surplus method—see inside front cover.

Adjust aq. phase to 5% alkali by adding 10 mL NaOH soln, (g). Ext Cd with 25 mL dithizone soln, (e), shaking vigorously  $\geq 1$  min, and transfer to third separator previously wetted with 2–3 mL same dithizone soln. Repeat extn with addnl 10 mL portions dithizone soln until  $\text{CCl}_4$  layer becomes colorless. Amts of Cd usually found in foods or biological materials (ca 100  $\mu\text{g}$ ) are completely removed by third extn.

To verify assumption that pale pink persisting after third extn is due to Zn, transfer questionable ext to fourth separator contg 5% NaOH soln, add several mL dithizone soln, (e), and shake vigorously. If  $\text{CCl}_4$  layer becomes colorless, original pink was due to Zn and no further extns are necessary. If, however, pink persists, indicating presence of Cd, add ext to contents of third separator, and continue extn.

Convert Cd and Zn dithizonates in third separator to chlorides by adding 40 mL 0.2N HCl and shaking vigorously  $\geq 1$  min. Carefully drain  $\text{CCl}_4$  layer, which may contain traces of Co and Ni not removed in second step, and discard. Remove droplets of dithizone from aq. phase by rinsing with 1–2 mL  $\text{CCl}_4$  and drain off as completely as possible, but do not permit any acid to pass bore of separator. Again adjust alkali to 5% by adding 10 mL NaOH soln, (g). Wipe separator stems dry with cotton, (i). Det. Cd present by adding exactly 25 mL dithizone soln, (e), shaking vigorously exactly 1 min, permitting layers to sep. exactly 3 min, and continuing as in 25.023, beginning "... filter org. layer..." Calc. Cd in  $\mu\text{g}$  by substituting A in linear equation or from std curve.

*Note:* If photometric measurement indicates  $>25 \mu\text{g}$  Cd, make first approximation by dilg dithizonate soln with  $\text{CCl}_4$  and evaluating A. For best results repeat analysis with wts or aliquots of samples contg  $\leq 25 \mu\text{g}$  Cd; 30  $\mu\text{g}$  is upper limit of solubility of Cd dithizonate in 25 mL  $\text{CCl}_4$ . Therefore amts  $>30 \mu\text{g}$  are incompletely extd.

#### Atomic Absorption Spectrophotometric Method (7) Official Final Action

(Caution: See 51.006, 51.019, 51.026, and 51.030.)

##### 25.026

##### Principle

Sample is digested with  $\text{HNO}_3$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{H}_2\text{O}_2$ . All reactive metals are extd from soln, after adjustment to ca pH 9, with dithizone- $\text{CHCl}_3$ . Cd is removed by stripping  $\text{CHCl}_3$  soln with dil. HCl and detd by AA spectrophotometry at 228.8 nm.

##### 25.027

##### Reagents and Apparatus

(Thoroughly wash all new glassware and glassware which has contained high Cd concn with 8N  $\text{HNO}_3$ , and rinse with  $\text{H}_2\text{O}$ . Cover beakers with watch glasses during all operations.)

(a) *Nitric acid*.—Low in Pb and Cd (G. Frederick Smith Chemical Co., No. 63).

(b) *Hydrogen peroxide*.—50% (Fisher Scientific Co., No. H-341).

(c) *Citric acid*.—Monohydrate, fine crystal.

(d) *Thymol blue indicator*.—See 25.022(h).

(e) *Dithizone solns*.—(1) *Concentrated soln*.—1 mg/mL. Prep. 200 mL in  $\text{CHCl}_3$ . (2) *Dilute soln*.—0.2 mg/mL. Dil. concd soln 1+4 with  $\text{CHCl}_3$ . Prep. fresh daily.

(f) *Cadmium std solns*.—(1) *Stock soln*.—1.0 mg/mL. Dissolve 1.000 g Cd, 25.022(j), in 165 mL HCl in 1 L vol. flask. Dil. to vol. with  $\text{H}_2\text{O}$ . (2) *Intermediate soln*.—10  $\mu\text{g}$ /mL. Dil. 10 mL stock soln with 2N HCl to 1 L. Prep. just before use. (3) *Working solns*.—Dil. 0, 1, 5, 10, and 20 mL intermediate soln to 100 mL with 2N HCl (0, 0.1, 0.5, 1.0, and 2.0  $\mu\text{g}$  Cd/mL, resp.).

(g) *Atomic absorption spectrophotometer*.—With hollow-

cathode Cd lamp and 10 cm burner head for air- $\text{C}_2\text{H}_2$  flame; wavelength 228.8 nm, range 0–2.0  $\mu\text{g}$ /mL.

##### 25.028

##### Digestion

Weigh 50.0 g sample into 1.5 L beaker. Add several boiling chips or beads, and cover. Carefully add 25 mL  $\text{HNO}_3$ , cover, and warm gently with flame to initiate reaction. (Meker-type burners are preferred thruout for their versatility and speed.) When reaction subsides, add 25 mL  $\text{HNO}_3$ , warm again, and continue until 100 mL  $\text{HNO}_3$  has been added. (Alternatively, add 100 mL  $\text{HNO}_3$  all at once, with caution, and let stand at room temp. overnight.) Heat until most NO fumes have evolved; control excessive frothing by cooling or quenching with  $\text{H}_2\text{O}$  from wash bottle. Only some cellulose and fatty materials, if any, remain undissolved.

To remove any fat visible in hot soln, proceed as follows: Cool beaker in ice, and decant clear, aq. soln from coagulated oils and solids thru glass wool pad into 1 L beaker. Add 100 mL  $\text{H}_2\text{O}$  to 1.5 L beaker with fat, heat, swirl vigorously to rinse fat, chill, and filter as before. Wash funnel and glass wool pad with ca 20 mL  $\text{H}_2\text{O}$ .

Add 20 mL  $\text{H}_2\text{SO}_4$  to sample, dil. to ca 300 mL with  $\text{H}_2\text{O}$ , and evap. over flame until charring begins. When charring becomes extensive, cautiously add 50%  $\text{H}_2\text{O}_2$ , 1 mL at time. Let reaction subside before adding next portion of oxidant, and never add  $>1$  mL at a time. Continue addns of  $\text{H}_2\text{O}_2$  until soln is colorless. Heat vigorously to  $\text{SO}_3$  fumes, adding more  $\text{H}_2\text{O}_2$  as required to remove char. Heat vigorously to expel excess  $\text{H}_2\text{O}_2$ . Cool colorless digest to room temp.

Prep. reagent blank of 100 mL  $\text{HNO}_3$ , 20 mL  $\text{H}_2\text{SO}_4$ , and same amts of  $\text{H}_2\text{O}$  as added to sample. Cautiously add same amts 50%  $\text{H}_2\text{O}_2$ , as above, and remove all  $\text{HNO}_3$  from blank. Carry blank thru same operations as sample.

##### 25.029

##### Extraction

Add 2 g citric acid to cooled digest and cautiously dil. to ca 25 mL with  $\text{H}_2\text{O}$ . Add 1 mL thymol blue indicator and adjust to ca pH 8.8 by slowly adding  $\text{NH}_4\text{OH}$  while cooling in ice bath, until soln changes from yellowish green to greenish blue. Transfer quant. to 250 mL separator, using  $\text{H}_2\text{O}$ , and dil. to ca 150 mL.

Cool soln, and ext with two 5 mL portions concd dithizone soln, shaking 1–2 min each time. Continue extn with 5 mL portions dil. dithizone soln until last 5 mL portion dithizone ext shows no change in color. Combine dithizone exts in 125 mL separator; wash with 50 mL  $\text{H}_2\text{O}$ , and transfer solv. to another 125 mL separator. Ext  $\text{H}_2\text{O}$  wash with 5 mL  $\text{CHCl}_3$  and add this to dithizone exts. Add 50 mL 0.2N HCl to combined dithizone exts, shake vigorously 1 min, and let layers sep.; discard dithizone layer. Wash aq. soln with 5 mL  $\text{CHCl}_3$  and discard  $\text{CHCl}_3$ . Quant. transfer aq. soln to 400 mL beaker, add boiling chips, and evap. carefully to dryness. Carefully rinse down sides of beaker with 10–20 mL  $\text{H}_2\text{O}$  and again evap. to dryness.

##### 25.030

##### Determination

Set instrument to previously established optimum conditions, using air- $\text{C}_2\text{H}_2$  oxidizing flame and 228.8 nm resonant wavelength. Dissolve dry residue in 5.0 mL 2N HCl and det. A of sample and std solns against 2N HCl as blank. Flush burner with  $\text{H}_2\text{O}$  between readings. Use scale expansion controls to obtain 4–10 $\times$  expansion, as convenient. Det. Cd from curve of A against  $\mu\text{g}$  Cd/mL:

$$\text{ppm Cd} = (\mu\text{g Cd/mL}) \times (\text{mL 2N HCl/g sample}).$$

For concn  $>2.0 \mu\text{g}$  Cd/mL, dil. soln with 2N HCl.

**Cadmium and Lead in Earthenware (8)**  
**Official Final Action**

**AOAC-ASTM Method**

**25.031**

**Apparatus**

*Atomic absorption spectrophotometer.*—Equipped with 4" single slot or Boling-type burner head and operated as follows: Pb hollow cathode lamp, 283.3 or 217.0 nm; Cd hollow cathode lamp, 228.8 nm; flame, air-C<sub>2</sub>H<sub>2</sub>. (*Caution:* See 51.006.) App. should have sensitivity of ca 0.5 µg Pb/mL and 0.25 µg Cd/mL for 1% absorption. Use operating conditions specified by manufacturer.

**25.032**

**Reagents**

(Use glassware of chemically resistant borosilicate glass.)

(a) *Acetic acid.*—4%. Mix HOAc and H<sub>2</sub>O (1+24). Analyze each new batch of reagent for Pb and Cd.

(b) *Detergent wash.*—Add 15 g alk. detergent (e.g., Calgonite, Calgon Corp., PO Box 1346, Pittsburgh, PA 15230, or equiv.) to 1 gal. (3.8 L) lukewarm tap H<sub>2</sub>O.

(c) *Lead std solns.*—(1) *Stock soln.*—1000 µg/mL. Dissolve 1.5985 g Pb(NO<sub>3</sub>)<sub>2</sub> in 4% HOAc and dil. to 1 L with same soln. (2) *Working solns.*—Dil. 0.0, 5.0, 10.0, 15.0, and 20.0 mL stock soln to 1 L with 4% HOAc (0, 5, 10, 15, and 20 µg/mL).

(d) *Cadmium std solns.*—(1) *Stock soln.*—1000 µg/mL. Dissolve 0.9273 g anhyd. CdSO<sub>4</sub> in 250 mL HCl (1+37), and dil. to 500 mL with HCl (1+37). (2) *Intermediate soln.*—10 µg/mL. Dil. 10 mL stock soln to 1 L with 4% HOAc. (3) *Working solns.*—Dil. 0.0, 3.0, 5.0, 10.0, 15.0, and 20.0 mL intermediate soln to 100 mL with 4% HOAc (0.0, 0.3, 0.5, 1.0, 1.5, and 2.0 µg/mL).

**25.033**

**Extraction**

Take, at random, 6 identical units of product and cleanse each with detergent wash. Rinse with tap H<sub>2</sub>O followed by distd H<sub>2</sub>O, and dry. Fill each unit with 4% HOAc from graduate to within 6–7 mm of overflowing. (Measure distance along surface of test unit, not vertical distance.) Record vol. acid required for each unit in sample. Cover each unit with clear, colorless glass plate to prevent evapn of soln, avoiding contact between cover and surface of leaching soln, and expose to normal laboratory light for 8–10 hr during leaching period. Let stand 24 hr at room temp. (22±2°).

If test unit is extremely shallow or has scalloped brim, evapn losses should be anticipated. In those cases, record headspace after filling. After 24 hr leaching period, adjust soln vol. to same recorded headspace, using 4% HOAc.

**25.034**

**Determination**

(a) *Lead.*—Set instrument for max. signal at 283.3 or 217.0 nm, using Pb hollow cathode lamp and air and C<sub>2</sub>H<sub>2</sub> flow rates recommended by manufacturer. Stir sample soln and decant portion into clean flask. Det. A of sample and Pb working std solns. Flush burner with H<sub>2</sub>O and check 0 point between readings. Det. Pb from std curve of A against µg Pb/mL or calibrate DCR unit in concn mode with Pb working solns, and read and record sample concn directly. Bracket sample soln with next higher and lower working solns.

Dil. samples contg >20 µg Pb/mL with 4% HOAc. Conc. samples contg <1 µg Pb/mL by accurately transferring min. of 50.0 mL of soln to 250 mL beaker and evapg to dryness on steam bath. Dissolve residue in 4% HOAc by adding exactly 0.1 vol. of soln taken for concn (i.e., for 50.0 mL soln, add exactly 5.0 mL 4% HOAc), cover with watch glass, and swirl to complete dissoln. Det. Pb as above, except substitute "3.0 mL" and "3

µg/mL" for "20.0 mL" and "20 µg/mL", resp., in 25.032(c)(2).

(b) *Cadmium.*—Proceed as for Pb, setting instrument for max. signal at 228.8 nm, using Cd hollow cathode lamp. Dil. samples contg >2 µg Cd/mL with 4% HOAc. Conc. samples contg <0.1 µg/mL as in (a)

Report type of units tested and for each, vol. acid used and Pb and Cd leached in µg/mL.

**Rapid Screening Method (9)—Official First Action**

(Detects 0.3 µg Pb and 0.05 µg Cd/mL 4% HOAc)

**25.035**

**Reagents**

(a) *Buffer soln I.*—Dissolve 1 g NH<sub>2</sub>OH.HCl and 10 g NH<sub>4</sub> citrate in 150 mL H<sub>2</sub>O, make soln alk. to phenol red indicator by adding NH<sub>4</sub>OH, and add 5 g KCN, 975 mL NH<sub>4</sub>OH, and 1315 mL H<sub>2</sub>O. Mix well. Add 16 mL this buffer soln to 8 dram screw-cap vial for field test. (*Caution:* See 51.050.) (Buffer is good for 16 tests.)

(b) *Sodium hydroxide soln.*—40% (w/v). (*Caution:* See 51.037.)

(c) *Potassium sodium tartrate soln.*—Dissolve 25 g C<sub>4</sub>H<sub>4</sub>O<sub>6</sub>KN<sub>2</sub>·4H<sub>2</sub>O in 100 mL H<sub>2</sub>O; mix well.

(d) *Sodium hydroxide-potassium cyanide soln.*—Dissolve 40 g NaOH and 1 g KCN in 100 mL H<sub>2</sub>O; mix well.

(e) *Hydroxylamine, hydrochloride soln.*—Dissolve 20 g NH<sub>2</sub>OH.HCl in 100 mL H<sub>2</sub>O. Transfer soln to 250 mL separator and ext with 5 mL portions 0.01% (w/v) dithizone in CHCl<sub>3</sub> until last ext remains green; then wash soln free from excess dithizone with 10 mL portions CHCl<sub>3</sub>. Transfer soln to 250 mL beaker, warm to remove excess CHCl<sub>3</sub>, cool, and filter into 100 mL flask.

(f) *Buffer soln II.*—Mix reagents (b) : (c) : (d) : (e) in ratio of 1:1:5:1, and add 8 mL prepd buffer to 8 dram screw-cap vial for field test. (Buffer is good for 16 tests.)

(g) *Conditioned chloroform.*—Redistd CHCl<sub>3</sub>, stabilized with 20 mL absolute alcohol/L. (*Caution:* See 51.056.)

(h) *Dithizone reagent.*—Add 75 mg diphenylthiocarbazone to 250 mL vol. flask, dissolve in conditioned CHCl<sub>3</sub>, (g), and dil. to vol. Add 0.5 mL this soln to 1 dram screw-cap vial and evap. to dryness without heat. (Dithizone reagent, when reconstituted with 2 mL CHCl<sub>3</sub>, is good for 16 tests.)

(i) *Acetic acid soln.*—(4%) HOAc-H<sub>2</sub>O (1+24). Analyze each new batch of reagent for Pb and Cd as in 25.034(a) and (b).

**25.036**

**Extraction**

Take, at random, 2 identical units of product, wipe clean to remove surface contaminants, and designate as Y and Z. Add 150 mL 4% HOAc soln, (i), to each unit and let stand 30 min. If 150 mL does not completely cover decoration, if present, add 4% HOAc until it does. (Note: If test is conducted in cold weather, warm HOAc to >65°F.)

**25.037**

**Determination**

(a) *Test for lead.*—Using pipet or calibrated dropper, add 1 mL buffer soln I, (a), to each of three 10 × 75 mm test tubes. Add 0.25 mL 4% HOAc soln (equiv. to 7 drops using 2 mL Pasteur pipet; hold pipet almost horizontal to obtain proper size drop) to 1 test tube; add 0.25 mL leach soln from unit Y to second tube and 0.25 mL from unit Z to third tube. Reconstitute dithizone reagent in vial, (h), by adding 2 mL CHCl<sub>3</sub>, (g). Add 0.125 mL reconstituted dithizone reagent to each test tube (due to surface tension and density of CHCl<sub>3</sub>, 13 drops = 0.125 mL when disposable Pasteur pipet is used). Close end of tube with inverted hollow stopper (9 × 15 mm, Mallinckrodt P310-001, or equiv.) and shake ca 10 sec. Let layers sep. and observe color

of lower  $\text{CHCl}_3$  layer. Definite change from reagent blank color indicates possible presence of Pb. Verify pos. results by 25.033–25.034(a).

(b) *Test for cadmium*.—Using pipet or calibrated dropper, add 0.5 mL buffer soln II, (f), to each of three 10 × 75 mm test tubes. Add 0.6 mL (17 drops using 2 mL disposable Pasteur pipet) 4% HOAc soln (reagent blank) to 1 test tube, add 0.6 mL leach soln from unit Y to second tube, and 0.6 mL from unit Z to third tube. Continue as in (a), beginning "Reconstitute dithizone reagent in vial, (h), by adding 2 mL  $\text{CHCl}_3$ , . . ." Definite change from reagent blank color indicates possible presence of Cd. Verify pos. results by 25.033–25.034(b).

## COPPER

### International Union of Pure and Applied Chemistry Carbamate Method (10)—Official Final Action

#### 25.038

#### Principle

Sample is digested with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ . Cu is isolated and detd colorimetrically at pH 8.5 as diethyldithiocarbamate in presence of chelating agent, EDTA. Bi and Te also give colored carbamates at pH 8.5 but are decomposed to colorless compds with 1*N* NaOH. Cu complex is stable. Range of color development is 0–50  $\mu\text{g}$ . Blank is ca 1  $\mu\text{g}$  Cu.

#### 25.039

#### Precautions

Clean glassware with hot  $\text{HNO}_3$ . Use white petrolatum to lubricate stopcocks of separators, and do not use brass chains. Purify  $\text{H}_2\text{O}$  and  $\text{HNO}_3$  by distn in Pyrex.

#### 25.040

#### Reagents

(a) *Sodium diethyldithiocarbamate (carbamate soln)*.—Dissolve 1 g of the salt in  $\text{H}_2\text{O}$ , dil. to 100 mL, and filter. Store in refrigerator and prep. weekly.

(b) *Citrate-EDTA soln*.—Dissolve 20 g dibasic  $\text{NH}_4$  citrate and 5 g  $\text{Na}_2\text{EDTA}$  (Eastman Kodak Co.) in  $\text{H}_2\text{O}$  and dil. to 100 mL. Remove traces of Cu by adding 0.1 mL carbamate soln and extg with 10 mL  $\text{CCl}_4$ . Repeat extn until  $\text{CCl}_4$  ext is colorless.

(c) *Copper std solns*.—(1) *Stock soln*.—1 mg/mL. Place 0.2000 g Cu wire or foil into 125 mL erlenmeyer. Add 15 mL  $\text{HNO}_3$  (1+4), cover flask with watch glass, and let Cu dissolve, warming to complete soln. Boil to expel fumes, cool, and dil. to 200 mL. (2) *Intermediate soln*.—100  $\mu\text{g}/\text{mL}$ . Dil. 20 mL stock soln to 200 mL. (3) *Working soln*.—2  $\mu\text{g}/\text{mL}$ . Prep. daily by dilg 5 mL intermediate std soln to 250 mL with 2.0*N*  $\text{H}_2\text{SO}_4$ .

(d) *Ammonium hydroxide*.—6*N*. Purify as in (b).

(e) *Thymol blue indicator*.—0.1%. Dissolve 0.1 g thymol blue in  $\text{H}_2\text{O}$ , add enough 0.1*N* NaOH to change color to blue, and dil. to 100 mL.

#### 25.041

#### Preparation of Sample

(Caution: See 51.026 and 51.030.)

Weigh sample contg  $\leq 20$  g solids, depending upon expected Cu content. If sample contains  $< 75\%$   $\text{H}_2\text{O}$ , add  $\text{H}_2\text{O}$  to obtain this diln. Add initial vol.  $\text{HNO}_3$  to equal ca 2 times dry sample wt and 5 mL  $\text{H}_2\text{SO}_4$ , or as many mL  $\text{H}_2\text{SO}_4$  as g dry sample, but  $\geq 5$  mL. Digest as in 25.008.

When sample contains large amt of fat, make partial digestion with  $\text{HNO}_3$  until only fat is undissolved. Cool, filter free of solid fat, wash residue with  $\text{H}_2\text{O}$ , add  $\text{H}_2\text{SO}_4$  to filtrate, and complete digestion as above. After digestion, cool, add 25 mL  $\text{H}_2\text{O}$ , and remove nitrosylsulfuric acid by heating to fumes. Repeat addn of 25 mL  $\text{H}_2\text{O}$  and fuming. If after cooling and dilg, insol. matter

is present, filter thru acid-washed paper, rinse paper with  $\text{H}_2\text{O}$ , and dil. to 100 mL.

Prep. reagent blank similarly.

#### 25.042

#### Isolation and Determination of Copper

Pipet 25 mL sample soln into 100 or 250 mL short-stem separator and add 10 mL citrate-EDTA reagent. Add 2 drops thymol blue indicator, (e), and 6*N*  $\text{NH}_4\text{OH}$  dropwise until soln turns green or blue-green. Cool, and add 1 mL carbamate soln and 15 mL  $\text{CCl}_4$ . Shake vigorously 2 min. Let layers sep. and drain  $\text{CCl}_4$  through cotton pledget into g-s tube or flask. Det A or T in suitable instrument at ca 400 nm.

If  $> 50 \mu\text{g}$  Cu is present in 25 mL aliquot, use smaller aliquot and dil. to 25 mL with 2.0*N*  $\text{H}_2\text{SO}_4$ . Highest accuracy is obtained at ca 25  $\mu\text{g}$  Cu level (A ca 0.3 in 1 cm cell).

To test for Bi and Te, return  $\text{CCl}_4$  soln to separator, add 10 mL 5% KCN soln, and shake 1 min. If  $\text{CCl}_4$  layer becomes colorless, Bi and Te are absent.

If test is pos., develop color in another 25 mL aliquot as above (without KCN). Drain  $\text{CCl}_4$  layer into second separator, add 10 mL 1*N* NaOH, and shake 1 min. Let layers sep. and drain  $\text{CCl}_4$  into third separator. Again wash  $\text{CCl}_4$  ext with 10 mL 1*N* NaOH. Det. A or T of  $\text{CCl}_4$  layer and convert to  $\mu\text{g}$  Cu.

#### 25.043

#### Preparation of Standards and Calibration Curves

Transfer 0, 1, 2.5, 5, 10, 15, 20, and 25 mL of Cu std soln (2  $\mu\text{g}/\text{mL}$ ) to separators and add 2.0*N*  $\text{H}_2\text{SO}_4$  to make total vol. of 25 mL.

Add 10 mL citrate-EDTA reagent and proceed as in 25.042, beginning "Add 2 drops thymol blue indicator, . . ."

Plot A against  $\mu\text{g}$  Cu on ordinary graph paper. If readings are in % T, use semilog paper, and plot T on log scale. Since there is usually some deviation from linearity, read sample values from smoothed curve.

### Atomic Absorption Method (11)—Official Final Action

(Applicable to copper and nickel in tea)

#### 25.044

#### Principle

Samples are wet ashed and after diln are detd by AA at 232.0 nm (Ni) and 324.7 nm (Cu). Matrix of std solns is matched to that of sample to avoid interference from Na and K.

#### 25.045

#### Apparatus

*Atomic absorption spectrophotometer*.—Capable of measuring content or change of content of 0.05  $\mu\text{g}$  Ni or Cu/mL in aq. soln.

#### 25.046

#### Preparation of Standard Solutions

(a) *Copper std soln*.—1000  $\mu\text{g}/\text{mL}$ . Dissolve 1.000 g 99.99% Cu in 20 mL  $\text{HNO}_3$ , cool, and dil. to 1 L with  $\text{H}_2\text{O}$ .

(b) *Nickel std soln*.—1000  $\mu\text{g}/\text{mL}$ . Dissolve 1.000 g 99.99% Ni in 20 mL  $\text{HNO}_3$ , cool, and dil. to 1 L with  $\text{H}_2\text{O}$ .

(c) *Matrix std solns*.—Prep. solns contg 0, 0.2, 0.4, 0.8, 1.6, 2.0, 4.0, 8.0, and 10  $\mu\text{g}$  Ni and Cu/mL and major metal matrix components: (1) *For 3 g sample tea*.—To contain 180  $\mu\text{g}$  Ca, 100  $\mu\text{g}$  Mg, and 40  $\mu\text{g}$  Al/mL with final concn of 8% (v/v)  $\text{HClO}_4$ . (2) *For 6 g sample instant tea*.—To contain 7000  $\mu\text{g}$  K, 70  $\mu\text{g}$  Na, 700  $\mu\text{g}$  Mg, and 130  $\mu\text{g}$  Ca/mL with final  $\text{HNO}_3$  concn of (1+9).

## 25.047

**Preparation of Calibration Curve**

(Caution: See 51.006 and 51.026.)

Let instrument stabilize. Optimize conditions for Cu or Ni according to manufacturer's instructions.

Aspirate 10  $\mu\text{g/mL}$  std enough times to establish that *A* reading is not drifting. Record 6 readings and calc. std deviation ( $\sigma$ ) =  $(x - y) \times 0.40$ , where *x* and *y* are max. and min. readings, resp., and 0.40 is factor to convert range of 6 values to  $\sigma$ .

Beginning with soln contg 0 Cu, aspirate each matrix std soln and record *A*. If value for 10  $\mu\text{g/mL}$  soln differs from av. of the 6 values used to calc.  $\sigma$  by  $>0.01 \times (\text{av. of the 6 values})$ , repeat measurements. If these detns indicate drift, det. cause (e.g., deposits in burner or clogged capillary), correct it, and repeat calibration. Repeat for Ni solns. Plot *A* against  $\mu\text{g metal/mL}$ .

## 25.048

**Determination**

Select sample wt to give soln contg  $\geq 0.05$  but  $\leq 10 \mu\text{g Ni/mL}$ , usually 3 g for teas and 6 g for instant teas.

(a) *Wet ashing*.—Accurately weigh sample into 400 mL beaker, add 100 mL  $\text{HNO}_3$ , and swirl. Cover, and let react 10 min; then place on hot plate. Evap. to near dryness and cool. Add 50 mL  $\text{HNO}_3$ , and for tea, add 10 mL  $\text{HClO}_4$ . Continue evapn to obtain clear soln. (Caution: See 51.019, 51.026, and 51.028.)

Transfer to 50 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . (Insol.  $\text{KClO}_4$  which settles to bottom of flask does not interfere.)

Prep. reagent blank contg same amts of acids taken from same lots, evapd as above.

(b) *Photometry*.—Aspirate sample and blank solns, and record *A*. Measure *A* of matrix std soln contg 10  $\mu\text{g/mL}$ . If this value differs from value of av. of the 6 values used to calc.  $\sigma$  by  $>2\sigma$ , repeat measurement. If these values indicate drift, det. cause, correct it, and repeat calibration and sample and blank readings.

(c) *Calculations*.—Correct readings of sample soln for blank. Convert corrected *A* to  $\mu\text{g/mL}$  from calibration curve.

$$\text{ppm Ni (or Cu)} = (C \times V)/W,$$

where *C* =  $\mu\text{g metal/mL}$  from curve, *V* = final vol. sample soln (50), and *W* = g sample.

**FLUORINE (72)—OFFICIAL FINAL ACTION**

## 25.049

**Principle**

Sample is ashed with  $\text{Ca(OH)}_2$  as F fixative; F is isolated by Willard-Winter distn (Ind. Eng. Chem., Anal. Ed. 5, 7(1933)) from  $\text{HClO}_4$ , and estd in distillate by  $\text{Th(NO}_3)_4$  back-titrn method (JAOAC 27, 246(1944)). Technic and reagent concns are designed to handle  $\leq 10.0 \text{ mg F}$  conveniently. Modifications applicable to specific products are described.

## 25.050

**Precautions and Interferences**

Control magnitude of detn blank by careful choice and purification of reagents (see 25.052). With care, blank will be low (1–3  $\mu\text{g F}$ ), but with low-F foods it may represent considerable part of total F detd; hence, it must be stable. Large part of it will be "distn blank" apparently resulting from F leached from glassware of still during distn. This blank can be minimized by preliminary treatment of stills, 25.054, and av. distn blank detd if stills of same material and design are routinely used; otherwise, each still must bear its special blank. New, unused stills will usually be found to exhibit high blank, which will diminish to const low figure after several detns. They should not be used until several consecutive blank detns yield const, low amt of F.

Check ashing utensils by blank detns with fixative soln to det. if they contribute appreciable F. Even Pt vessels may become contaminated (owing presumably to slight Ca content) if they have been used recently for HF volatilization of  $\text{SiO}_2$ . In addn, such blank detns are useful for testing reagents and app. used in method and also evaporators, hoods, furnaces, and laboratory atm. for presence of F fumes and dust. If HF bottles are permitted in same laboratory, seal immediately after use; avoid contamination from roach powders.

Ordinary tap  $\text{H}_2\text{O}$  may be source of F contamination, since 1 mL  $\text{H}_2\text{O}$  contg 2 ppm F will contribute 2  $\mu\text{g F}$  if allowed to remain or to dry in still. Therefore, routinely rinse all glassware (stills, flasks, burets, etc.) with  $\text{H}_2\text{O}$ , preferably redistd from alk.  $\text{KMnO}_4$ . Filter papers may contribute  $\mu\text{g}$  amts of F, and glass filters are preferred if filtration is required in micro detns.

*Interferences* are gelatinous  $\text{SiO}_2$ , Al, and B compds, which repress evolution of F as  $\text{H}_2\text{SiF}_6$  in distn; materials such as nitrates, nitrites, peroxides, Cl,  $\text{SO}_2$ , and  $\text{H}_2\text{S}$ , which act upon indicator in titrn or otherwise interfere; halides (Cl), which distil to give excessive acidity in distillate; and phosphates and sulfates, which react with Th in titrn to give high results. Method is so designed that most of these interferences are automatically eliminated, but analyst should be on guard against their possible occurrence under unusual circumstances.

**General Method**

## 25.051

**Apparatus**

(a) *Fluorine still*.—Claisen 100–125 mL distg flask is most practical for general work. It must be of Pyrex glass with auxiliary neck sealed off immediately above side arm to prevent pocketing and refluxing of distillate. Still should be as small and simply designed as practicable; ordinary distg flasks can be used for some work and they are slightly more efficient than Claisen type, except that danger of spraying over of distg acid is greater.

Equip still with dropping funnel and 0–150° thermometer, latter extending to within 6 mm of bottom of flask, so that bulb is immersed in boiling acid mixt. Acid-alkali washed beads, preferably Pyrex, should be on hand. Clean rubber stoppers by boiling in 10% NaOH soln. All-glass app. with  $\text{F}$  accessories is convenient, especially in routine work, and eliminates need for rubber stoppers.

While not entirely necessary for heating still, use of Wood metal (50 Bi, 25 Pb, 12.5 Sn, 12.5 Cd) bath, adequately shielded, will prevent undue decomposition of  $\text{HClO}_4$ , and aid materially in securing low blank and low-acid distillate; hence, its use is strongly urged. If metal bath is used, do not immerse flask so deeply that bath level is above that of liq. in flask; if bath is not used, transite or asbestos shielding boards are essential, and flask should be heated thru small hole in such shield by low "clean" flame. (Bath and shielding boards prevent over-heating of upper still walls.)

At analyst's option, distg  $\text{H}_2\text{O}$  may be added as steam instead of thru dropping funnel; elec. boiler, Fig. 18:02, is convenient steam generator. If steam is used, inlet tube should dip below surface of liq. in still. One advantage in adding distg  $\text{H}_2\text{O}$  thru funnel is that last portions of rinse  $\text{H}_2\text{O}$  used in transferring an ash can be used in distn. If funnel plug is thinly notched with sharp file on either side of bore, dropping rate can be more easily controlled, and end of funnel stem need not extend into liq. in still. Still is used in conjunction with clean straight-tube condenser no longer than necessary for adequate cooling. (Vertical arrangement of condenser will conserve bench space.)

(b) *Nessler tubes*.—Tall-form, 100 and 50 mL, g-s type preferred. Matched in sets of  $\geq 6$ . (100 mL size is used most frequently in general method.)

(c) *Additional apparatus.*—(See 25.050.) Carefully cleaned and tested Pt, or well-glazed porcelain, dishes of  $\geq 100$  mL size; 150 mL vol. flasks, or if these are not available, 200 mL size; and 10 mL burets (conveniently automatic) to deliver various solns required in distn and titrn. Overhead radiant heater will be found invaluable for drying and preliminary charring of samples, especially those of high-sugar type.

## 25.052

## Reagents

(Caution: See 51.011, 51.025, 51.028, and 51.030.)

(a) *Lime suspension.*—Carefully slake ca 56 g (1 mole) low-F CaO (ca 2 ppm F) with ca 250 mL  $H_2O$ , and *slowly* add 250 mL 60%  $HClO_4$  with stirring. Add few glass beads and boil down to copious fumes of acid; cool, add 200 mL  $H_2O$ , and boil down again. Repeat diln and boiling down once more; cool, dil. considerably, and filter thru fritted glass filter, if pptd  $SiO_2$  appears. Pour clear soln, with stirring, into 1 L NaOH soln (100 g/L), let ppt settle, and siphon off supernate. Remove Na salts from ppt by washing 5 times in large centr. bottles, shaking mass thoroly each time. Finally, shake ppt into suspension and dil. to 2 L. Store in paraffined bottles. (100 mL of this suspension should give no appreciable F blank when evapd, distd, and carried thru titrn, (l).) Always shake suspension well before use.

(b) *Perchloric acid soln.*—60%. Dil.  $HClO_4$  with 3–4 vols  $H_2O$  and boil down to original vol. Do not fume strongly. Repeat, and store in Pyrex. (Prepd acid should be Cl-free by test.)

(c) *Sulfuric acid soln.*—Carefully mix equal vols  $H_2SO_4$  and  $H_2O$ , boil down to fumes, cool, dil. *carefully*, boil down once more, and dil. to 1+1 vol.

(d) *Silver perchlorate soln.*—50 g/100 mL.

(e) *p-Nitrophenol indicator.*—0.5% alc. soln.

(f) *Potassium hydroxide soln.*—Exactly 0.05N.

(g) *Potassium chloride soln.*—0.05N. 3.728 g/L.

(h) *Hydroxylamine hydrochloride soln.*—1.0%.

(i) *Hydrochloric acid soln.*—Exactly 0.05N.

(j) *Alizarin indicator.*—0.01% aq. soln of sodium alizarin sulfonate (Alizarin Red S).

(k) *Potassium fluosilicate std solns.*—(1) *Stock soln.*—0.5 mg F/mL. Dissolve and dil. 0.9661 g (corrected for purity as indicated below)  $K_2SiF_6$  to 1 L (much more will not dissolve). Soln keeps indefinitely in paraffined bottle. (2) *Working soln.*—10  $\mu$ g F/mL. Prep soln used in titrn, 25.055, by dilg 20 mL stock soln to 1 L. Soln is stable several weeks in ordinary volumetric ware.

If pure  $K_2SiF_6$  is not obtainable, prep. as follows: Add, thru dropping funnel, satd soln of NaF, or suspension of crude  $K_2SiF_6$ , into 500 mL Claisen distg app. contg 60 mL  $H_2SO_4$  (1+1), some glass beads, and 10–20 g powd  $SiO_2$  (or glass) kept at boiling temp. of 120–125°. Distil into 25% soln of KCl, held at simmering temp. on hot plate so that vol. of distillate does not become excessive. If necessary, add more  $H_2O$  to mixt. from dropping funnel in side-neck of still. Regulate rate of addn of NaF to still and temp. of condensing  $H_2O$  so that side arm and condenser do not become clogged with evolved  $H_2SiF_6$ , which tends to lodge as gelatinous mass.  $K_2SiF_6$  is formed in receiver, and altho entirely cryst. it assumes appearance of gelatinous mass.

When substantial amt collects, pour contents of receiver into large centr. bottle and wash repeatedly by centrfg (shaking up ppt thoroly each time), until washings are Cl-free by test. Collect on buchner and either air dry or bring to const wt *in vacuo* at 50–70°.

Det. purity by Travers titrn, 6.022, at boiling temp. with 0.2N NaOH (1 mL = 0.01101 g  $K_2SiF_6$ ); also by conversion to  $K_2SO_4$  by treating 0.3–0.4 g in deep Pt dish with little  $H_2O$ , then  $H_2SO_4$ , plus little HF, fuming off excess acid *carefully* (if overheated, mixt. has tendency to spatter), and heating to const wt of  $K_2SO_4$

at 650°. With glass app., entirely pure product is not usually obtained, as some contamination with  $SiO_2$  results from leaching effect of vapors on condenser. Pure product can be obtained by use of Pt still. Prep. stock soln, correcting wt of 0.9662 by purity factor of the  $K_2SiF_6$  (figure for purity obtained from av. of 2 above methods of assay).

(l) *Thorium nitrate soln.*—0.25 g  $Th(NO_3)_4 \cdot 12H_2O$  or 0.20 g  $Th(NO_3)_4 \cdot 4H_2O$ /L. Check titer against std (10  $\mu$ g/mL) F soln as follows: Measure 10, 20, 30, etc., up to 80  $\mu$ g F into 100 mL Nessler tubes, and add 4.00 mL 0.05N HCl (2.00 mL if 50 mL Nessler tubes are used, and limiting range to only 50  $\mu$ g F) (JAOAC 24, 350(1941)). Dil. mixt. to ca 80 (or 40) mL mark and add 1.00 mL 1.0%  $NH_2OH \cdot HCl$  soln. Mix; then add exactly 2.00 mL alizarin indicator (or 1.00 mL for smaller tube) and add Th soln from buret, mixing frequently until, when sighting down tube toward white reflecting surface, incipient pink or salmon pink color is observed. Add little  $H_2O$  occasionally so that soln is nearly to mark as end point is approached. Finally, dil. exactly to mark and mix thoroly before checking final end point. Do not shake tube vigorously (5–6 gentle inversions are enough).

Make effort to secure end point shade intermediate between yellowish green of acid indicator and reddish purple of fully developed Th lake. Complete series and plot mL Th soln against mL std fluoride to obtain rough equivalence curve for 2 solns. Depending upon amt of F known to be present, add Th soln in 1–2 mL portions at first, with final addns of 0.25 mL.

## 25.053

## Preparation of Sample

(Caution: See 51.011 and 51.028.)

Methods of sample prepn are designed to furnish representative sample in workable amt of material and to obtain sample in condition for final distn. Mineralization by ashing is usually involved. Some mineral food products can be dissolved in and distd from  $HClO_4$ , 25.054, provided no interferences appear in final distillate.

In general,  $\geq 20$  g dry material, 50–100 mL liq. samples, and 50–100 g undried food products or plant material can be taken for analysis, depending upon expected F content and interferences, such as excessive Cl, which use of large samples may introduce. For reasonable precision in analysis of low-F foods, sample should be sufficient to yield titer of  $\geq 0.5$  mL for aliquot taken in final titrn. However, it may not always be possible to handle this amt of material. If adequate grinding and mixing equipment is available, it is often feasible to prep. large amts of material (vegetables, mixed foods) and to take aliquot portions for analysis (Ind. Eng. Chem., Anal. Ed. 13, 93(1941)).

Dry plant materials, feeds, bone meal, etc., can be ground to convenient size in Wiley mill and thoroly mixed before sample is taken. Following special methods for certain products are indicated:

(a) *Direct ashing.*—Applicable to fibrous (not highly fatty) foods, liq. samples and, in general, to all foods that can be thoroly wet with aq. fixative soln. This method will apply to majority of food products.

Weigh suitable portion of prepd sample into clean Pt dish and add 25 mL  $Ca(OH)_2$  suspension. (Porcelain casseroles or dishes are second choice because they may contribute small amts of F and  $Al_2O_3$  to sample.) Mix in  $Ca(OH)_2$  suspension with glass rod, adding addnl  $H_2O$  if necessary; rinse and remove rod. Dry *thoroly* on steam bath or in hot air oven; then slowly char sample by heating over low flame or elec. plate with thermostat. Overhead radiant heater is convenient for both drying and charring sample. Control excessive swelling of high sugar foods by playing small flame over surface of sample from time to time, and char these products *slowly* so that excessive acidity

is not generated. When sample is charred past danger of catching fire, ash in furnace at 600°. (For very small samples and min. blanks, it may be advisable to cover ashing vessel with inverted Pyrex petri dish while ashing.)

For plants high in silica, fusion with NaOH may be necessary (Anal. Chem. **25**, 450, 1061(1953)).

When clean ash is obtained, cool dish and wet ash with ca 10 mL H<sub>2</sub>O. (Small amt of unburned C does not interfere but if much is apparent, dry down and repeat ashing.) Cover dish with watch glass and cautiously introduce under cover just enough HClO<sub>4</sub> soln to dissolve ash. Rinse down cover with little H<sub>2</sub>O and transfer soln to freshly prepd F still, **25.054**, thru long-stem funnel. Rinse dish with remainder of distg acid, using ca 20 mL in all, and adding and transferring in several small portions. *Do not prolong transferring operation.* Finally rinse funnel and stirring rod into dish, assemble still, and complete rinsing of dish with several small portions H<sub>2</sub>O, pouring these into dropping funnel of still. If distg H<sub>2</sub>O is added as steam, **25.051(a)**, rinse dish with little addnl H<sub>2</sub>O and add directly to acid mixt. in still, but avoid excessive initial vol. Add ca 6 Pyrex beads and enough AgClO<sub>4</sub> soln, **25.052(d)**, to ppt all Cl. (Reasonable excess of AgClO<sub>4</sub> does no harm; enough solid Ag<sub>2</sub>SO<sub>4</sub> may also be used.) Proceed as in **25.054**.

(b) *Preliminary distillation.*—(Necessary with certain products high in phosphate, such as Ca phosphate and bone meal, in order to eliminate distd H<sub>3</sub>PO<sub>4</sub> that may be present in appreciable amts in first distillates. Also advisable with certain excessively fatty materials that may not be thoroly wet with Ca(OH)<sub>2</sub> fixative, thus causing F loss in direct ashing method.)

(1) *For inorganic phosphatic materials, such as Ca phosphate.*—Weigh sample, usually 10 g, into still; add few glass beads, enough AgClO<sub>4</sub> to ppt possible Cl, and ca 20 mL HClO<sub>4</sub> soln. (If inorg. phosphatic material does not contain excessive Ca (enough to cause heavy ppt of CaSO<sub>4</sub> in still), use similar amt of 1+1 H<sub>2</sub>SO<sub>4</sub>.) Distil at 135–140°, collecting ca 200 mL distillate. (For this preliminary distn, extreme care in securing low-acid distillate is not essential.) Evap. distillate to dryness in Pt dish after addn of excess Ca(OH)<sub>2</sub> suspension, assuring alk. conditions by testing with drop of phthln. (If H<sub>2</sub>SO<sub>4</sub> is used in this preliminary distn, add few drops *F-free* 30% H<sub>2</sub>O<sub>2</sub> to distillate to oxidize possible sulfites.) Heat dried residue at 600° few min to destroy indicator residues and possible Cl-contg compds. Transfer contents of dish to freshly prepd still, **25.054**, with 20 mL distg HClO<sub>4</sub> soln as in (a), and proceed with final distn as in **25.054**.

Take 20 mL samples of sirupy H<sub>3</sub>PO<sub>4</sub> and collect ≥300 mL first distillate at 135°, letting H<sub>3</sub>PO<sub>4</sub> function as its own distg acid. (More distillate is necessary because H<sub>3</sub>PO<sub>4</sub> is less effective as F distg acid.) Neutze with Ca(OH)<sub>2</sub> suspension, evap. to dryness, transfer to prepd still as above, and proceed as in **25.054**.

(2) *For organic phosphatic materials, such as bone meal, feed supplements, etc.*—As preliminary ashing treatment to destroy most org. matter, moisten sample with enough Ca(OH)<sub>2</sub> suspension, dry, char, and heat 2–3 hr at 600°. Transfer ashed material to still, which contains several beads and enough AgClO<sub>4</sub> to ppt Cl, with 20 mL distg acid (HClO<sub>4</sub> or H<sub>2</sub>SO<sub>4</sub>, depending on Ca content of sample) as in (a), and continue as in (b)(1), beginning, "Distil at 135–140°, . . ."

*Certain org. phosphatic materials* (small samples of bone, 2–5 g, such as entire bones of small test animals) *in which amt of org. matter is not excessive*, may be distd directly as in (b)(1) without preliminary ashing. If sample contains appreciable Ca (bone samples), use HClO<sub>4</sub> with reasonable precaution; if org. phosphatic material does not contain excessive Ca, use 1+1 H<sub>2</sub>SO<sub>4</sub>. In either case, add more Ca(OH)<sub>2</sub> to first distillates and ash for longer periods to completely destroy distd org. matter

(fatty acids). Transfer contents of dish to freshly prepd still, **25.054**, with 20 mL HClO<sub>4</sub> soln as in (a) and proceed with final distn, **25.054**.

*Baking powders* (Ca phosphate and combination types): Place 10 g sample in deep, covered Pt dish or casserole and slake cautiously with ca 20 mL Ca(OH)<sub>2</sub> suspension. After action subsides, rinse cover, dry contents of dish *thoroly*, and ash 2–3 hr at 600°. Cool dish and, because of excess of carbonate in ash, treat it with several small portions of warm H<sub>2</sub>O, breaking up with flat-end stirring rod, and transfer leachings to still. Transfer remaining contents of dish with 20 mL HClO<sub>4</sub> soln, avoiding excessive effervescence when acid is added to carbonate soln in still. Add several glass beads and enough AgClO<sub>4</sub> soln, and proceed as in (b)(1), beginning, "Distil at 135–140°, . . ." With *combination* or *Na Al sulfate* baking powders, collect ≥400 mL preliminary distillate, (b)(4).

Use of special still trap makes possible analysis of highly phosphatic *inorg.* or *thoroly* ashed materials, and phosphoric acids, with single distn. Special trap, or scrubber, consists of 12–15 g small, hollow glass beads supported in side-neck of the 125 mL Claisen flask by several indentations punched in side wall, and capped by glass disk or inverted bottom of 15 mm test tube. After construction of glass-bead scrubber, side-neck is sealed off immediately above outlet tube. (Beads in scrubber must be wet with little H<sub>3</sub>PO<sub>4</sub> (by tipping flask) before distn to furnish liq. acid phase.) Take 20 mL sirupy H<sub>3</sub>PO<sub>4</sub>, by itself, and 10 g samples Ca phosphate with 20 mL HClO<sub>4</sub> soln, for distn, and collect ≥400 mL distillate at 135°. With single distn, observe precautions in **25.051(a)**, and also in **25.054**, regarding neutzn of final distillates. (Distillates should show practically no acidity.) Presence of only *traces* of distd H<sub>3</sub>PO<sub>4</sub> will vitiate titrn; as little as 20 µg P<sub>2</sub>O<sub>5</sub> will definitely interfere. Accordingly, if single distn procedure is to be applied with confidence, it is necessary to test distillates obtained from phosphatic materials, by means of the special still, for presence of this interference.

For convenient test utilizing Schricker reagent (JAOAC **22**, 167(1939)), add 5 mL of 1+9 diln of this reagent to 45 mL distillate in 50 mL graduate or Nessler tube, mix, and immerse in steam bath 5–10 min. Compare against blank by sighting down tube. Blue or blue-green color indicates phosphate, and as little as 5 µg (as P<sub>2</sub>O<sub>5</sub>) is readily detected. If distillate shows traces, make sure that such amts are below interference level of 15 µg in titrn aliquot before titrg addnl portions of distillate. (Test with Schricker reagent is also useful in usual double distn where phosphate interference is possible. Use of special trap will save time where highly phosphatic materials are handled routinely, but it is not justified in ordinary work because of poor efficiency owing to excessive refluxing in distn.)

(3) *For excessively fatty and oily food materials (oil-packed foods, certain meats, etc.; also entire undried and unground organs of test animals).*—If there is danger of F loss thru incomplete wetting with Ca(OH)<sub>2</sub> fixation soln, handle as follows: Weigh appropriate amt of sample, usually 10–25 g, into still, and add Ag (preferably 0.1–0.2 g solid Ag<sub>2</sub>SO<sub>4</sub>), several glass beads, and 20–25 mL H<sub>2</sub>SO<sub>4</sub> (1+1). Distil at 130–135° and collect 200–250 mL distillate in beaker or open vessel. If foaming is excessive, increase vol. of distg acid, and where necessary, use larger (250–300 mL) still. If larger still or more acid is used, collect proportionately more of first distillate. (Oil or fat of many of these products will tend to prevent foaming, and, in some instances, use of ca pea-size piece of pure paraffin is addnl aid.)

Oxidize distillate in cold by cautious addn of 2–3 mL *F-free* 30% H<sub>2</sub>O<sub>2</sub> to remove sulfites, let stand few min, and evap. portionwise in Pt dish contg excess (10–15 mL) Ca(OH)<sub>2</sub> suspension. Ash residue at 600° until clean. Proceed as in (b)(1), beginning "Transfer contents of dish to freshly prepd still, . . ."

Handle pure oils by similar procedure: Use 10 g sample with 25 mL  $\text{H}_2\text{SO}_4$  (1+1) and carry temp. at first to ca  $170^\circ$  to saponify; then carefully bring temp. down to  $140^\circ$  with distg  $\text{H}_2\text{O}$  and collect  $\geq 250$  mL distillate. (It will probably be necessary to use higher reading thermometer for this procedure.) Oxidize distillate with 30%  $\text{H}_2\text{O}_2$  and evap. to dryness after adding excess  $\text{Ca}(\text{OH})_2$  suspension. Ash at  $600^\circ$  and after brief preliminary ash period remove dish, add little  $\text{H}_2\text{O}$  plus addnl 1–2 mL of the  $\text{H}_2\text{O}_2$  to remove sulfides, dry, and complete ashing. Proceed as in (b)(1), beginning "Transfer contents of dish to freshly prepd still, . . ."

(4) *For aluminum and boron compounds.*—Al and B repress evolution of F. Isolate F by preliminary distn at elevated temp. For this purpose, weigh sample, usually 5–10 g, into still, add 25 mL  $\text{H}_2\text{SO}_4$  (1+1), and conduct first distn at  $160$ – $165^\circ$  (special thermometer), collecting 300 mL distillate. Oxidize distillate with 30%  $\text{H}_2\text{O}_2$  as above, evap. in Pt dish with excess  $\text{Ca}(\text{OH})_2$  suspension, ash briefly at  $600^\circ$ , and proceed as in (b)(1), beginning, "Transfer contents of dish to freshly prepd still, . . ."

**25.054****Final Distillation**

(Caution: See 51.011 and 51.028.)

Always make final distn from  $\text{HClO}_4$ , and take precautions to secure low-acid distillate, 25.051(a). Since interferences, such as org. matter, phosphate, sulfate, etc., must be absent from distillate, make distn with careful temp. control in presence of enough Ag salt to repress HCl evolution (25.050). It is well to check distillates for presence of possible phosphate as in 25.053(b)(2), and where advisable, as in (b)(4), to test for sulfate with little dil.  $\text{BaCl}_2$  soln.  $\text{HClO}_4$  used in final distn is usually used in transferring ash to still, 25.053(a). Few acid-alkali washed beads are used to control bumping. (Use of powd  $\text{SiO}_2$  does not appear necessary for microdetn.)

To promote better recoveries, and to minimize and render const distn blank discussed in 25.050 and 25.055, prep. still by special cleaning process before this transfer by treating it with hot 10% NaOH soln after each detn, flushing out with tap  $\text{H}_2\text{O}$ , and then rinsing with distd  $\text{H}_2\text{O}$ . Occasionally (at least once daily, and especially after it has stood idle for any length of time), give still addnl treatment by boiling down 15–20 mL  $\text{H}_2\text{SO}_4$  (1+1) until still is filled with fumes. Cool, pour off acid, treat with the 10% NaOH soln, and *thoroly* rinse out. (Cleaning should be especially meticulous after high-F or high- $\text{SiO}_2$  samples have been distd, and in such cases condenser should also be cleaned.)

At this stage, prepd sample has been transferred to specially treated still, as directed above, for final isolation of F. Begin distn, and when temp. reaches  $137^\circ$ , keep at this point ( $\pm 2^\circ$ ) by adding  $\text{H}_2\text{O}$  from dropping funnel, 25.051(a). Heat still at such rate that all distns require ca same time. (Time promotes uniformity in blank correction.) Collect distillate in 150 or 200 mL vol. flask. After few mL distillate collects, add 1–2 drops *p*-nitrophenol indicator, (e), and keep distillate alk. to this indicator (faintest perceptible yellow) by occasionally adding 1–2 drops 0.05N KOH from 10 mL buret during distn while swirling receiver. So regulate this addn of alkali that distillate is neutzd (within 1 drop of alkali) as it approaches mark. Carefully note vol. alkali used. Dil. distillate to vol. and mix thoroly. Do not let F distillate stand more than few min before neutzg.

If sample contains such large amts of Cl that bumping in still cannot be controlled, dissolve ash of another sample, and acidify *slightly* with  $\text{HClO}_4$ . Dil. considerably and ppt Cl in dish with  $\text{AgClO}_4$  soln, avoiding large excess. Filter thru glass filter, wash ppt *thoroly* with hot  $\text{H}_2\text{O}$ , and evap. filtrate and washings to dryness after adding excess (to alky) of  $\text{Ca}(\text{OH})_2$  suspension.

Transfer residue to still with  $\text{HClO}_4$  soln and repeat distn as above.

**25.055****Titration**

(Caution: See 51.011 and 51.028.)

Place aliquot of final distillate in Nessler tube and mark "S" (sample). (Optimum F content for titrn is 60–70  $\mu\text{g}$  for 100 mL Nessler tubes and 30–40  $\mu\text{g}$  for 50 mL size, and it is well to make exploratory titrn on small aliquot to check approx. F content of distillate. Larger tubes are necessary for precise results on low-F foods.)

Add 0.05N HCl, 4.00 mL for 100 mL tubes and 2.00 mL for 50 mL size, and 1.00 mL  $\text{H}_2\text{NOH.HCl}$  soln. (For routine work with 100 mL tubes, dissolve 1.0 g  $\text{H}_2\text{NOH.HCl}$  in 500 mL 0.04N HCl and dil. to 500 mL. Then proper amt of both reagents can be added in single operation with 5 mL pipet.) Dil. to ca 90 (or 40) mL, mix well, then add alizarin indicator (2.00 or 1.00 mL), and mix again. Always add and mix in  $\text{H}_2\text{NOH.HCl}$  before adding indicator.

Prep. blank tube "B" by adding proper amt HCl and  $\text{H}_2\text{NOH.HCl}$ , and amt 0.05N KCl soln representing same proportion of total vol. of 0.05N KOH used to neutze distillate as aliquot vol. taken for sample tube represents of total distillate vol. (Thus, if 1.50 mL 0.05N KOH was used to neutze distillate of 150 mL and aliquot taken for tube "S" was 75 mL, add 0.75 mL 0.05N KCl to tube "B.") Dil. and mix, allowing slightly more headspace than in sample tube. Then add proper vol. alizarin indicator and mix.

Measure Th soln into tube "S," mixing between addns, until end point of about proper shade is reached. Dil. to mark, mix, and check this end point shade. Note from curve, 25.052(I), approx. vol. std F soln corresponding to this vol. Th soln, and add ca 0.5 mL *less* than this amt of std F soln to "B." Mix; then add exactly same vol. Th soln as was added to "S," duplicating approx. increments in which it was added and number of mixings. Dil. nearly to mark and compare colors of "S" and "B." (If vol. std F soln added to "B" was properly chosen, this tube should be only slightly pinker in shade than sample tube.)

Bleach "B" tube to exact match with tube "S" by adding more std F soln to "B" in increments of 1–2 drops, mixing gently between addns. Dil. to mark for final comparison and observe usual precautions of letting bubbles subside and of transposing tubes when final comparisons are made. (At match-point, F content of tube "S" equals amt added to tube "B.") Check this end point by adding 1–2 drops excess std F soln to tube "B." Distinct overbleach should develop.

Repeat titrn on aliquots of different size to obtain total amt of F distd. If time is available, repeat entire detn with different wt sample.

*For precise work*, evaluation of reagent and of distn blank is necessary, 25.050. Det. distn blank by making several distns with prescribed amts  $\text{HClO}_4$  and  $\text{AgClO}_4$  solns from freshly cleaned still, titrg distillate as above with as large aliquot as practicable. Av. of values found should be  $\leq 3 \mu\text{g}$  F. If amts found by individual blank detns are too small to be detd accurately, make  $\geq 5$  sep. distns and evap. distillates, 150 mL each time, successively in same Pt dish for final distn and average blank figure. Distn and total detn blanks can usually be *combined* by carrying run (with same amts of reagents and similar evapn and ashing treatment) thru entire detn. Reagents and manipulations should increase distn blank but little.

Calc. total amt F distd from amt found in aliquot titrd, subtract proper blank, and refer net figure to wt sample taken. If double distn procedure was used, make appropriate blank correction.

### Rapid Method Restricted to Fluoride Residues on Apples and Pears

#### 25.056

#### Principle

Add filtrate from strip soln of apples and pears prep'd with HCl rinse and acidification, **25.106**, is used. Aliquot of filtrate is oxidized colorless with  $\text{KMnO}_4$ , soln is then reduced with  $\text{H}_2\text{NOH}$ , and subaliquot is backtitrd in Nessler tubes;  $\text{Zr}(\text{NO}_3)_4$  is used in titrn, with purpurin (1,2,4-trihydroxyanthraquinone) as indicator (Ind. Eng. Chem., Anal. Ed. **6**, 118(1934)). Principle of back-titrn, as applied here, is similar to that used in general method where  $\text{Th}(\text{NO}_3)_4$  and alizarin occupy similar roles. Provision is made for removal of interfering anions, and high acidity used in titrn minimizes interference of metals that would otherwise lake with indicator.

#### 25.057

#### Apparatus

*Nessler tubes.*—50 mL g-s, tall-form, matched for ht and color (see **25.060**).

#### 25.058

#### Reagents

(a) *Mixed nitrate soln.*—Dissolve 3.0 g  $\text{Ba}(\text{NO}_3)_2$  and 2.0 g  $\text{Th}(\text{NO}_3)_4 \cdot 4\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , and dil. to 100 mL.

(b) *Potassium permanganate soln.*—Satd; ca 6%.

(c) *Hydroxylamine hydrochloride soln.*—5%.

(d) *Ferrous chloride soln.*—Dissolve ca 1.0 g Fe powder or wire in 50 mL HCl (1+1), dil., and filter into 500 mL vol. flask. Add few mL 5%  $\text{H}_2\text{NOH} \cdot \text{HCl}$  soln and dil. to vol. Dil. still further before use, if desired.

(e) *Purpurin indicator.*—0.01% in alcohol. Dissolve 25 mg pure 1,2,4-trihydroxyanthraquinone in alcohol, heating if necessary, and dil. to 250 mL with same solv. Prep. fresh weekly.

(f) *Zirconium nitrate soln.*—Dissolve 1.50 g  $\text{Zr}(\text{NO}_3)_4 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , acidify with 20 mL HCl, and dil. to 1 L. Filter if not clear.

(g) *Fluoride std soln.*—54.5  $\mu\text{g}$  F/mL. Dissolve 0.1464 g NaF in  $\text{H}_2\text{O}$  and dil. to 1 L.

#### 25.059

#### Determination

Place 20 mL well mixed acid strip filtrate, **25.106**, in 50 mL vol. flask. Add 2.0 mL mixed nitrate soln, then 4.0 mL  $\text{KMnO}_4$  soln. Rinse down neck of flask with little  $\text{H}_2\text{O}$  and place on active steam bath 5 min. Remove flask, and while still hot, add 5%  $\text{H}_2\text{NOH} \cdot \text{HCl}$  soln from buret, slowly and with swirling, until  $\text{MnO}_2$  is dissolved and soln is colorless; then add ca 0.5 mL in excess. (Appreciable phosphate is revealed as flocculent  $\text{Th}_3(\text{PO}_4)_4$ , and sulfate as ppt with Ba. Sometimes  $\text{KMnO}_4$  is occluded in sulfate and/or phosphate ppt, and pink color tends to persist but does not interfere.) Cool, dil. to vol., and filter. (Filtrate must be clear. If there is perceptible turbidity, return filtrate thru filter several times if necessary, until filtrate is *brilliant*.) Pipet 25 mL clear filtrate into Nessler tube and mark "S."

For blank or comparison tube use 25 mL "blank" soln, contg reagents used in method, prep'd as follows:

Dil. 50 mL 10% Na oleate soln, **25.095(k)**, 50 mL 30 g/100 mL NaOH soln, and 15 mL HCl to 1 L. Acidify portions with  $1/10$  vol. HCl as if soln were an actual "strip," and filter, refiltering until filtrate is perfectly clear. (Chilling soln and shaking vigorously will "churn" pptd oleic acid and aid in obtaining clear filtrate.) Carry 20 mL portions of acidified filtrate thru method exactly as above. (In order more closely to duplicate conditions of actual detn, use 50 mL vol. flasks and 20 mL aliquots in preference to using larger aliquots with correspondingly larger amts of reagents. After being dild to vol. and filtered, blank soln may be combined to form supply of "blank"; 10 portions worked up as above yield ca 500 mL "blank," or enough for ca 20 detns.)

Add 25 mL of this "blank" to second Nessler tube, "B," and to both tubes "S" and "B" add 15.0 mL HCl measured as carefully as possible from graduate. (Always add acid to soln instead of vice versa.) Mix, and match tubes for color. "S" tube will usually be found to have slight greenish tint in comparison with "B" tube, due presumably to traces of Fe. Balance both tubes to same shade by adding  $\text{FeCl}_2$  soln dropwise to appropriate tube and mixing. *This operation must be done carefully.* When tints are indistinguishable, add exactly 1.00 mL purpurin indicator to each tube. Mix; then add 1.50 mL Zr soln to each tube from 10 mL buret, and mix. Do not shake tubes violently when mixing in reagents; 4 or 5 gentle inversions are enough. Observe color difference, if any, between tubes when looking down their length toward white reflecting surface. If there is no appreciable difference *after 5 min*, F content of sample is negligible. If color of tube "S" is yellower, presence of F is indicated. In this case, add addnl amts of  $\text{Zr}(\text{NO}_3)_4$  soln to tube "S" until its color about matches that of tube "B" (to nearest 0.5 mL Zr soln). Dil. "S" to mark and mix.

Now add to "B" exactly same total vol. Zr soln as was added to tube "S," mix, and let tube stand 2 min for lake to develop fully. Back-titr. std F soln into "B" from 10 mL buret until tubes match, mixing frequently, and dilg nearly to vol. as end point approaches. Add NaF soln in increments of ca 0.1 mL at this stage, and observe usual precautions of transposing and letting bubbles subside when making comparisons. Dil. to mark for final comparison. Check end point by adding 0.1–0.2 mL std F soln in excess. Distinct overbleach should develop.

For sample wt of 1 kg and aliquots specified above, each mL std F soln consumed in back-titrn is equiv. to F content on fruit sample, *removable by solv. treatment*, of 3.0 ppm. Correct result obtained in titrn by sample wt ratio. (Thus, titer of 3.27 mL std F soln, with 1.40 kg sample (ca 10 fruit), represents F content of 7.0 ppm. Vol. restrictions of 50 mL Nessler tube will allow estn of spray residue content up to ca 11 ppm F.) If calibration mark is exceeded in back-titrn, use 10 mL aliquot of acid filtrate in tube "S," and dil. to 25 mL with "blank" soln, correcting titer of std F soln by appropriate factor.

#### 25.060

#### Notes on Rapid Method

G-s Nessler tubes are almost essential with concd acid prescribed in this detn. Analysts familiar with Th-alizarin back-titrn method should have no difficulty with Zr-purpurin titrn. With latter, however, color changes are not so apparent and titrn is less sensitive. However, with careful work, results accurate to  $\geq 0.5$  ppm may be expected.

Indicator color at prescribed acidity is yellow, and fully laked indicator is orange-red. This contrasts with Th titrn where corresponding range is from yellowish green to reddish purple. Hence, in rapid method, choice of end point involves discrimination between varying shades of orange. Addn of 1.50 mL Zr soln to tube "B" at start is merely to provide intermediate shade of orange to guide analyst in amt of Zr to be added to tube "S." Analysts may prefer to work with redder or yellower end point shade. In any event, make number of titrns by adding varying amts of std F soln as unknowns to Nessler tubes and carrying thru back-titrn as above, for purpose of learning color changes involved. Pure aq. solns instead of "blank" may be used, with acidities of 20 mL HCl/50 mL.

Accuracy of results with rapid method presupposes complete removal of spray residue F by solv. process and good accuracy (not necessarily precision) in titrn. These conditions may not always hold; unless carefully done, solv. method may not be entirely effective, and result on strip solns contg known amts of F have tended to be slightly low. Hence accuracy  $>95\%$  is not to be expected with this method.

## LEAD

## 25.061

## Principle

Instrumental methods, polarography and atomic absorption (AA) spectrophotometry, are generally more reliable than colorimetric method at lower concns. Method 25.063–25.067 is particularly applicable to samples contg high Ca concn. Special instrumental methods optimized for evapd milk and fish are given in 25.068–25.092.

General colorimetric method calls for ashing, 25.096, sepn of Pb, either as dithizone complex, 25.098, or as sulfide, 25.099, followed by colorimetric dithizone detn, 25.100, in comparator tubes, or with spectrophtr. Interference is treated sep., 25.101–25.103, and analyst should familiarize himself with details of these sections before applying method. Special methods of sample prepn are given in 25.104–25.105.

## 25.062

## Precautions

Analyst should decide whether nature of detn requires unusual care in purification of reagents, or whether blank detn will suffice. Smaller the amt of Pb to be detd, greater the care required in reduction of blank (see also 25.100).

To test suitability of reagents, place 10–15 g solid reagents dissolved in redistd H<sub>2</sub>O or 15–20 mL concd acids previously neutrd with redistd NH<sub>4</sub>OH in separator and add enough Pb-free citric acid to prevent pptn by NH<sub>4</sub>OH of Fe, Al, alk. earth phosphates, or other substances. Make soln ammoniacal and add 2–3 mL 10% KCN soln. Shake soln with ca 5 mL dithizone soln, 25.095(e) (5–10 mg/L). If lower layer is green, transfer it to another separator and ext excess dithizone with NH<sub>4</sub>OH (1+99) to which has been added drop of KCN soln. If CHCl<sub>3</sub> layer is colorless, consider test neg. for use with dithizone methods.

When special purification becomes necessary, redistil H<sub>2</sub>O (distd H<sub>2</sub>O stored in Sn-lined tanks usually contains Pb and Sn), HNO<sub>3</sub>, HCl, HBr, Br, and CHCl<sub>3</sub> in all-glass stills (preferably Pyrex). Prep. NH<sub>4</sub>OH by distg ordinary reagent into ice-cold redistd H<sub>2</sub>O. If stills are new, steam them out with hot HCl or HNO<sub>3</sub> vapors to remove "surface" Pb. (Subsequent distillates may not be totally Pb-free.)

Pb(NO<sub>3</sub>)<sub>2</sub> may be purified as follows: Dissolve 20–50 g in min. of hot H<sub>2</sub>O and cool with stirring. Filter crystals with suction on small buchner, redissolve, and recrystallize. Dry crystals at 100–110° to const wt. Cool in desiccator and store in tightly stoppered bottle. (Product has no H<sub>2</sub>O of crystn and is not appreciably hygroscopic.)

Purify citric acid, NaOAc or NH<sub>4</sub>OAc, Al(NO<sub>3</sub>)<sub>3</sub>, Ca(NO<sub>3</sub>)<sub>2</sub>, and Na<sub>2</sub>SO<sub>4</sub> by pptg Pb from their aq. solns with H<sub>2</sub>S (Caution: See 51.059), using 5–10 mg CuSO<sub>4</sub> as coprecipitant (citric acid and Al(NO<sub>3</sub>)<sub>3</sub> solns require adjustment with NH<sub>4</sub>OH to pH 3.0–3.5, bromophenol blue indicator). Filter (fritted glass filter is most convenient), boil filtrates 20 min to expel excess H<sub>2</sub>S, and refilter if necessary to obtain brilliantly clear solns. Purify other reagents by recrystn.

Store redistd acids or purified solns of reagents in resistant glass containers of min. Pb content (Pyrex is suitable), carefully cleaned of surface Pb with hot HNO<sub>3</sub>. Paraffin-lined bottles may be used for alk. reagents.

Carefully clean new glass and chemical ware with hot 10% NaOH soln followed by hot HNO<sub>3</sub>, and use only for Pb detns.

In prepn of samples for analysis, avoid Pb contamination. If mixing or grinding is necessary, use porcelain mortar if possible. Avoid use of metal food grinders unless previous experiment has shown that no contamination of sample with Pb or Sn results. If product to be analyzed cannot be thoroly mixed in its

own container, or if composite sample of number of containers is desired, empty into large glass jar or porcelain dish and mix thoroly with wooden spoon or porcelain spatula. If liq. portion of sample cannot be incorporated into ground solid material to obtain homogeneous mixt., analyze sep. If food is packed in tins having soldered seams (sardines and meats), open tins from bottom to avoid contaminating sample with bits of solder. Avoid sifting in prepn of samples to prevent metallic contamination or segregation of Pb.

Atomic Absorption Spectrophotometric Method (13)  
Official Final Action

## 25.063

## Principle

(Caution: See 51.006, 51.019, 51.026, 51.028, and 51.030.)

Org. matter is digested and Pb released coppts with SrSO<sub>4</sub>. Sol. sulfate salts are decanted, and ppt is converted to carbonate salt, dissolved in acid, and detd by AA at 217 or 283.3 nm.

## 25.064

## Apparatus

(a) *Atomic absorption spectrophotometer*.—Operated at 217 or 283.3 nm. (Caution: See 51.006.)

(b) *Stirring motor*.—With eccentric coupling for stirring centrf. tubes (Sargent-Welch Scientific Co. Model S-76509 (Vortex, Jr.), or equiv.).

## 25.065

## Reagents

(Age all new glassware and all glassware which has contained high Pb concn in boiling HNO<sub>3</sub> before washing. *Never* let used glassware dry before washing, and *always* include final HNO<sub>3</sub> rinse followed by deionized H<sub>2</sub>O rinse.)

(a) *Strontium soln*.—2%. Dissolve 6 g SrCl<sub>2</sub>·6H<sub>2</sub>O in 100 mL H<sub>2</sub>O.

(b) *Ternary acid mixture*.—Add 20 mL H<sub>2</sub>SO<sub>4</sub> to 100 mL H<sub>2</sub>O, mix, add 100 mL HNO<sub>3</sub> and 40 mL 70% HClO<sub>4</sub>, and mix.

(c) *Nitric acid*.—Add 128 mL redistd HNO<sub>3</sub> to 500–800 mL distd or deionized H<sub>2</sub>O and dil. to 2 L. Redistd HNO<sub>3</sub> (G. Frederick Smith Chemical Co., No. 53) may be dild and used without redistn.

(d) *Lead std solns*.—(1) *Stock soln*.—1000 µg/mL. Dissolve 1.5985 g Pb(NO<sub>3</sub>)<sub>2</sub>, recrystd as in 25.062, in ca 500 mL 1N HNO<sub>3</sub> in 1 L vol. flask and dil. to vol. with 1N HNO<sub>3</sub>. (2) *Working solns*.—Prep. 100 µg Pb/mL by dilg 10 mL stock soln to 100 mL with 1N HNO<sub>3</sub>. Dil. 1, 3, 5, 10, 15, and 25 mL aliquots of this soln to 100 mL with 1N HNO<sub>3</sub> (1, 3, 5, 10, 15, and 25 µg Pb/mL, resp.).

## 25.066

## Separation of Lead

Accurately weigh sample contg ≤10 g dry matter and ≥3 µg Pb. Place in 500 mL boiling or Kjeldahl flask and add 1 mL 2% Sr soln, (a), and several glass beads. Prep. reagent blank and carry thru same operations as sample. Add 15 mL ternary acid mixt., (b), for each g dry matter and let stand ≥2 hr. Heat under hood or H<sub>2</sub>O vac. manifold system until flask contains only H<sub>2</sub>SO<sub>4</sub> and inorg. salts. (Note: Take care to avoid sample loss from foaming when heat is first applied, and when foaming occurs soon after sample chars. Remove heat and swirl flask before continuing digestion. Add HNO<sub>3</sub>, if necessary.)

Cool digest few min. (Digest should be cool enough to add ca 15 mL H<sub>2</sub>O safely, but hot enough to boil when H<sub>2</sub>O is added.) Wash while still hot into 40–50 mL tapered-bottom centrf. tube and swirl. Let cool, centrf. 10 min at 350×g, and decant liq. into waste beaker. (Film-like ppt on surface may be discarded.) Dislodge ppt by vigorously stirring with eccentric-coupled stirring motor. To complete transfer, add 20 mL H<sub>2</sub>O and 1 mL 1N

H<sub>2</sub>SO<sub>4</sub> to original flask and heat. *Do not omit this step* even though it appears transfer was complete in first wash. Wash hot contents of original digestion flask into centr. tube contg ppt. Swirl to mix, cool, centr., and decant liq. into waste beaker.

Dislodge ppt by stirring vigorously, add 25 mL *satd* (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> soln (ca 20%), and stir until all ppt is dispersed. Let stand 1 hr, centr., and decant liq. into waste beaker. Repeat (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> treatment.

After decanting, invert centr. tube on paper towel and drain all liq. Add 5 mL 1*N* HNO<sub>3</sub> (use larger vol. 1*N* HNO<sub>3</sub> in both sample and blank if >25 µg Pb is expected), stir vigorously to expel CO<sub>2</sub> or use ultrasonic bath 2–3 min, let stand 30 min, and centr. if ppt remains. (Use same technic for all samples.)

**25.067****Determination**

Set instrument to previously established optimum conditions, using air-C<sub>2</sub>H<sub>2</sub> oxidizing flame and 217 or 283.3 nm resonant wavelength. Det. *A* of sample and blank solns and ≥5 stds within optimum working range (10–80% *T*) before and after sample readings. Flush burner with 1*N* HNO<sub>3</sub> and check 0 point between readings. Det. Pb from std curve of *A* against µg Pb/mL:

$$\text{ppm Pb} = [(\mu\text{g Pb/mL}) \times (\text{mL } 1\text{N HNO}_3)]/\text{g sample.}$$

**Atomic Absorption Method for Evaporated Milk (14)**  
**Official Final Action**

**25.068****Principle**

Sample is dry-ashed; Pb is extd as the 1-pyrrolidinedicarbodithioate into BuOAc, and detd by AA spectrophotometry at 283.3 nm.

**25.069****Apparatus**

(a) *Atomic absorption spectrophotometer*.—Equipped with 4" single slot burner head. (Caution: See 51.006.)

(b) *Ashing vessels*.—Approx. 100 mL, flat-bottom Pt crucible or dish, Vycor or quartz tall-form beaker, or evapg dish (Corning Glass Works, No. 13180, or equiv.). Discard Vycor vessels when inner surfaces become etched.

(c) *Centrifuge*.—Capable of holding 15 mL conical tubes and centrfg at 2000 rpm.

(d) *Furnace*.—With pyrometer to control range of 250–600° with variation ≤10°.

**25.070****Reagents**

(a) *Nitric acid*.—1*N*. See 25.065(c).

(b) *Butyl acetate*.—Spectral grade, H<sub>2</sub>O-satd.

(c) *Ammonium 1-pyrrolidinedicarbodithioate* (APDC).—2%. Dissolve 2.00 g APDC in 100 mL distd or deionized H<sub>2</sub>O. Remove insol. free acid and other impurities normally present by 2–3 extns with 10 mL portions BuOAc.

(d) *Lead std solns*.—(1) *Stock soln*.—1 mg Pb/mL 1*N* HNO<sub>3</sub>. See 25.065(d)(1). (2) *Intermediate soln*.—5.0 µg Pb/mL. Pipet 5 mL stock soln into 1 L vol. flask, add 1 mL HNO<sub>3</sub>, and dil. to vol. with H<sub>2</sub>O. (Soln is stable several months if stored in polyethylene bottle.) (3) *Working solns*.—Pipet 20, 10, 5, and 2 mL intermediate soln into sep. 100 mL vol. flasks, and dil. to vol. with 1*N* HNO<sub>3</sub> (1.0, 0.50, 0.25, and 0.10 µg Pb/mL, resp.). Pipet 10 and 5 mL soln contg 0.50 µg Pb/mL into sep. 100 mL vol. flasks, and dil. to vol. with 1*N* HNO<sub>3</sub> (0.05 and 0.025 µg Pb/mL, resp.).

(e) *Citric acid soln*.—10%. Weigh 10.0 g Pb-free citric acid into 100 mL vol. flask, dissolve in H<sub>2</sub>O, and dil. to vol. Stopper flask and shake thoroly. If necessary, remove Pb impurity as in 25.062.

(f) *Bromocresol green*.—0.1%. pH range, 3.8 (yellow) to 5.4 (blue). Transfer 0.100 g bromocresol green, Na salt, to 100 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Use 1 drop/10 mL anal. soln.

**25.071****Ashing**

(Clean all glassware thoroly in HNO<sub>3</sub> (1+1).)

Weigh ca 25 g (to nearest 0.1 g) sample into ashing vessel. Dry samples overnight in 120° forced-draft oven. (Sample must be absolutely dry to prevent flowing or spattering in furnace.) Place sample in furnace set at 250°. *Slowly* (50° increments) raise temp. to 350° and hold at this temp. until smoking ceases. Increase temp. to 500° in ca 75° increments (sample must not ignite). Ash 16 hr (overnight) at 500°. Remove from furnace and let cool. Ash should be white and essentially C-free. If ash still contains excess C particles (i.e., ash is gray rather than white), proceed as follows: Wet with min. amt H<sub>2</sub>O followed by dropwise addn of HNO<sub>3</sub> (0.5–3 mL). Dry on hot plate. Transfer to furnace at 250°, slowly increase temp. to 500°, and continue heating 1–2 hr. Repeat HNO<sub>3</sub> treatment and ashing if necessary to obtain C-free residue. (Note: Local overheating or deflagration may result if sample still contains much intermingled C and especially if much K is present in ash (see 25.096).)

Dissolve residue in 5 mL 1*N* HNO<sub>3</sub>, warming on steam bath or hot plate 2–3 min to aid soln. Filter, if necessary, by decantation through S&S 589 black paper into 50 mL vol. flask. Repeat with two 5 mL portions 1*N* HNO<sub>3</sub>, filter, and add washings to original filtrate. Dil. to vol. with 1*N* HNO<sub>3</sub>.

Prep. duplicate reagent blanks for stds and samples, including any addnl H<sub>2</sub>O and HNO<sub>3</sub>, if used for sample ashing. Note: Do not "ash" HNO<sub>3</sub> in furnace, since Pb contaminant will be lost. Dry HNO<sub>3</sub> in ashing vessel on steam bath or hot plate, and then proceed as above.

**25.072****Extraction**

(Complete analysis on same day.)

Pipet 20 mL each working soln, reagent blank for stds (if different from that used for samples), sample soln, and appropriate reagent blank(s) for samples into sep. 60 mL separators. Treat each soln as follows: Add 4 mL citric acid soln, (e), and 2–3 drops bromocresol green indicator, (f). (Color of soln should be yellow.) Adjust pH to ca 5.4, using NH<sub>4</sub>OH initially and then (1+4) in vicinity of color change (first permanent appearance of light blue). Add 4 mL APDC soln, (c), stopper, and shake 30–60 sec. Pipet in 5 mL BuOAc, (b). Stopper separator and shake vigorously ca 30–60 sec. Let stand until layers sep. cleanly; drain and discard lower aq. phase. If emulsion forms or solv. layer is cloudy, drain solv. layer into 15 mL centr. tube, cover with Al foil or Parafilm, and centr. ca 1 min at 2000 rpm.

**25.073****Determination**

Set instrument to previously detd optimum conditions for org. solv. aspiration (3–5 mL/min), using 283.3 nm Pb line and air-C<sub>2</sub>H<sub>2</sub> flame adjusted for max. Pb absorption. Flame will be somewhat fuel-lean. Optimum position in flame for max. absorption should be just above burner top. If using recorder, DCR, etc., adjust to manufacturer's specifications. Depending upon signal-to-noise ratio, scale expansion up to 10× may be used. Check 0 point while aspirating H<sub>2</sub>O-satd BuOAc. Aspirate sample and std solns, flushing with H<sub>2</sub>O and then BuOAc between measurements. Record *A* of each soln.

Prep. std curve by plotting *A* of each std corrected for blank against concn of that std in µg Pb/mL BuOAc. Concn of std in BuOAc is 4 times that in aq. std. Det. Pb concn from std curve, using *A* corrected for sample reagent blank, if used.

$$\text{ppm Pb} = [(\mu\text{g Pb/mL from curve}) \times 5 (\text{mL BuOAc})] / (\text{g sample} \times 20/50)$$

### Anodic Stripping Voltammetric Method for Evaporated Milk (14)—Official Final Action

25.074

#### Principle

Evapd milk is dry-ashed and residue is dissolved in dil.  $\text{HNO}_3$ . Pb is electroanal. concd on hanging Hg drop or Hg film electrode, and detd by reversing potential sweep and measuring anodic current peak.

25.075

#### Apparatus

See 25.069(b) and (d), plus following:

*Polarograph*.—Capable of anodic stripping voltammetric measurements at  $\geq 0.05$  ppm Pb.

25.076

#### Ashing

Proceed as in 25.071.

25.077

#### Preparation of Standard Curve

Prep. stds as in 25.070(d) and 1N  $\text{HNO}_3$  reagent blank. Transfer 10–20 mL std soln to cell, depending on cell capacity. Adjust to  $25 \pm 1^\circ$ , and bubble N thru soln 5 min. Adjust gas inlet tube to let N flow gently above and across soln surface. If hanging drop Hg electrode is used, add fresh drop Hg to capillary tip with micrometer (Hg drop must be reproducible for each measurement), turn on stirrer motor, and electrolyze soln 1–10 min at  $-0.6$  v against satd calomel electrode (time depends on manufacturer's instructions). Stop stirring and let soln stand 30 sec. Linearly increase applied voltage (pos. voltage scan). Use manufacturer's instructions for rate of scan, e.g., 2–6 mv/sec. Measure wave ht at half-wave potential ( $-0.45 \pm 0.05$  v against satd calomel electrode). Plot  $\mu\text{g Pb/mL}$  std soln against wave ht  $\times$  sensitivity factor (*SF*). Repeat for each std soln and reagent blank soln. Prep. new curve with each batch of samples.

25.078

#### Determination

Transfer to cell same vol. sample soln as used in stdzn. Bubble N, add Hg drop, and apply voltage as in stdzn. Measure wave ht at appropriate potential and det. Pb concn by comparing wave ht of sample soln with that of std curve or analyze std soln immediately before or after sample soln (preferable when instrument scale factor must be changed).

Prep. reagent blank soln as in 25.071, last par., and analyze as above.

25.079

#### Calculations

Calc.  $\mu\text{g Pb/mL}$  as follows:

$$C = C' \{ [(WH \times SF) - (WH_B \times SF_B)] / [(WH' \times SF') - (WH'_B \times SF'_B)] \}$$

where *C* and *C'* =  $\mu\text{g Pb/mL}$  sample and std, resp.; *SF*, *SF'*, *SF<sub>B</sub>*, and *SF'<sub>B</sub>* = sensitivity factor settings of sample, std, and reagent blank (may be different for sample (*SF<sub>B</sub>*) and std (*SF'<sub>B</sub>*) solns, resp.; and *WH*, *WH'*, *WH<sub>B</sub>*, and *WH'<sub>B</sub>* = wave hts.

$$\text{ppm Pb} = (C \times 50) / \text{g sample}$$

### Direct Determination by Anodic Stripping Voltammetry (15) Official First Action

(Applicable to milk and fruit juices only)

25.080

#### Apparatus

(a) *Voltammetric analyzer*.—With staircase anodic stripping ramp and graphite electrode coated with thin film of Hg. Capable

of measuring 5 ng Pb in presence of dissolved O. (Solns cannot be deaerated). Peak area integration desirable. ESA Model 3010A Trace Metals Analyzer (Environmental Sciences Associates, Inc., 45 Wiggins Ave, Bedford MA 01730), or equiv.

(b) *Micropipets*.—50, 100, 200, and 300  $\mu\text{L}$ , pos. displacement type. (SML or Drummond, available from supply houses, or equiv.).

25.081

#### Reagents

(Use deionized  $\text{H}_2\text{O}$  to prep. std solns. Prep. and store solns in same Pyrex vol. flasks. Do not wash flasks with strong acids between use; just rinse 3 times with deionized  $\text{H}_2\text{O}$ . Always prep. same soln in same flask.)

(a) *Lead releasing reagent*.—Contg  $< 1$  ppb Pb. Acid soln of cation able to displace Pb from sample. Metexchange Reagent (Environmental Sciences Associates, Inc.), or equiv.

(b) *Lead std solns*.—(1) *Stock soln*.—1 mg/mL. Prep. as in 25.065(d)(1). (2) *Intermediate soln*.—10  $\mu\text{g/mL}$ . Pipet 1 mL stock soln into 100 mL vol. flask contg 1.0 mL  $\text{HNO}_3$  and ca 50 mL  $\text{H}_2\text{O}$ . Mix, and dil. to vol. Prep. each week. After soln is prepd 6 times in same flask, it is stable 1 month. (3) *Working soln for fruit juice detn*.—3  $\mu\text{g/mL}$ . Pipet 30 mL soln (2) into 100 mL vol. flask contg 0.7 mL  $\text{HNO}_3$  and ca 50 mL  $\text{H}_2\text{O}$ . Mix, and dil. to vol. (4) *Working soln for evaporated milk detn*.—1  $\mu\text{g/mL}$ . Prep. as in (3), using 10 mL soln (2) and 1.0 mL  $\text{HNO}_3$ . Working solns are stable 3 days. After being prepd 5 times in same flask, they are stable 2 weeks. (5) *Calibration solns*.—Evapd milk or fruit juice of type being detd, and contg  $\geq 0.5$  ppm added Pb.

25.082

#### Determination

Calibrate instrument according to manufacturer's directions. Mix aliquot of sample with releasing reagent, (a), and perform detn according to manufacturer's instructions. Data for ESA analyzer are as follows:

	Juice	Milk
Initial potential, v	$-1.025 \pm 0.005$	$-1.090 \pm 0.005$
Final potential, v	$-0.100 \pm 0.005$	$-0.100 \pm 0.005$
Sweep rate, mv/step	$14.0 \pm 0.05$	$10.50 \pm 0.05$
Integration set points, v	$-0.490 \pm 0.005$	$-0.490 \pm 0.005$
Sample size, $\mu\text{L}$	300	200

Run control or spiked sample with each 15–20 analyses in a series.

### Atomic Absorption Method for Fish (16) Official Final Action

25.083

#### Apparatus

(a) *Atomic absorption spectrophotometer*.—See 25.069(a); range 0–10  $\mu\text{g/mL}$ .

(b) *Lead lamp*.—Hollow cathode Pb lamp.

(c) *Crucible*.—Porcelain, ca 50 mL capacity and 5 cm deep; or tall-form Vycor or quartz beaker, 100 mL (Kontes Glass Co., K319000).

25.084

#### Reagents

(a) *Hydrochloric acid*.—1N. Dil. 82 mL HCl to 1 L with  $\text{H}_2\text{O}$ .

(b) *Lead std solns*.—(1) *Stock soln*.—1 mg Pb/mL 1N  $\text{HNO}_3$ . See 25.065(d). (2) *Working soln*.—10  $\mu\text{g Pb/mL}$ . Pipet 10 mL stock soln into 1 L vol. flask, add 82 mL HCl, and dil. to vol. with  $\text{H}_2\text{O}$ .

(c) *Buffer soln*.—Disperse 163 g EDTA in 200 mL  $\text{H}_2\text{O}$  in 2 L vol. flask and add enough  $\text{NH}_4\text{OH}$  to dissolve. Dil. 60 mL 70.5%  $\text{HClO}_4$  (Caution: See 51.028) by pouring carefully into ca 500 mL  $\text{H}_2\text{O}$  and cool. Dissolve 5.0 g  $\text{La}_2\text{O}_3$  in soln as follows: Add 8

drops Me orange indicator to ammoniacal EDTA soln and add  $\text{La}_2\text{O}_3$  to EDTA soln while stirring vigorously. If necessary, add  $\text{NH}_4\text{OH}$  to maintain alk. of above soln to Me orange. Dil. to 2 L.

**25.085****Reagent Blank**

(Caution: See 51.026.)

Before proceeding with analysis, test purity of reagents as follows: Evap. 4 mL  $\text{HNO}_3$  in crucible to dryness on hot plate or steam bath, dissolve residue in 1N HCl, and transfer to 25 mL vol. flask. Heat residue again successively with two 5 mL portions 1N HCl and add to flask. Cool, dil. to vol. with 1N HCl, and mix. Proceed with detn. Total reagent blank should be  $\leq 10 \mu\text{g Pb}$  (equiv. to 0.4 ppm in sample) for detns at levels  $\geq 1$  ppm. For detns at  $< 1$  ppm, purify reagents as in 25.062 to attain blank  $< 50\%$  of limiting level of concern.

**25.086****Preparation of Sample**

Weigh ca 25 g (to nearest 0.1 g) sample into crucible, (c), and dry 2 hr at  $135\text{--}150^\circ$ . Transfer to cold, temp.-controlled furnace and slowly raise temp. to  $500^\circ$ . Set control and check for maintenance of  $500^\circ$ . (Temp. as low as  $550^\circ$  may cause loss of Pb.) Ash overnight (16 hr). Remove sample, let cool to room temp., cautiously add 2 mL  $\text{HNO}_3$ , and swirl. Evap. carefully just to dryness on warm hot plate or steam bath. Transfer to cooled furnace, slowly raise temp. to  $500^\circ$ , and hold at this temp. 1 hr. Remove dish and cool. Repeat  $\text{HNO}_3$  ashing, if necessary, to obtain clean, practically C-free ash. Add 10 mL 1N HCl and dissolve ash by heating cautiously on hot plate. Transfer to 25 mL vol. flask. Heat ash residue again successively with two 5 mL portions 1N HCl and add to flask. Cool, dil. to vol. with 1N HCl, and mix.

**25.087****Preparation of Standard Curve**

Transfer 0, 1, 3, 5, 15, 25, and 50 mL Pb working soln, 25.084(b)(2), to sep. 50 mL vol. flasks and dil. to vol. with 1N HCl (0, 0.2, 0.6, 1.0, 3.0, 5.0, and  $10.0 \mu\text{g Pb/mL}$ , resp.). Set spectrophtr to previously established optimum conditions for max. signal at 283.3 nm. Use air- $\text{C}_2\text{H}_2$  flow rates recommended by manufacturer for std conditions for Pb. For digital concn readout, calibrate in concn mode with solns contg 0.2 and  $10.0 \mu\text{g Pb/mL}$ . Record concn directly after calibration of instrument. For strip chart readout, set amplification to give  $\geq 1\%$  absorption reading for  $0.2 \mu\text{g/mL}$  working soln and prep. std curve of  $A$  against  $\mu\text{g Pb/mL}$ .

**25.088****Determination**

Use aliquot of sample soln, 25.086, and proceed as in (a) or (b). Treat reagent blank, 25.085, as sample and subtract reading from  $A$  of samples.

(a) *Clear solns.*—Det.  $A$  of sample and std solns as in 25.087, using following sequence 3 times: Read std soln first, then sample soln, alternating until all sample and std solns have been read. When many samples are to be analyzed, std solns may be read after series of 3 samples instead of after each.

$$\text{ppm Pb} = [(\mu\text{g Pb/mL sample soln}) \times 25] / \text{g sample.}$$

(b) *Cloudy solns.*—Proceed as in (a), but add 1 mL buffer soln, (c), to aliquots of sample and std solns before reading.

If addnl dilns are necessary or if buffer is added:

$$\text{ppm Pb} = (\mu\text{g Pb/mL dild sample}) \times (\text{mL dild sample/mL original aliquot}) \times (25/\text{g sample}).$$

**Polarographic Method for Fish (16)**  
**Official Final Action**

**25.089****Apparatus**

*Polarograph.*—Any voltammetric or polarographic instrument with necessary accessories (cells, electrodes, Hg, capillaries, etc.) capable of effectively scanning up to 3.0 volts in either pos. or neg. direction, starting at selected initial potential, and of measuring  $\geq 1.0$  ppm Pb.

**25.090****Preparation of Standard Curve**

Transfer 0, 1, 3, 5, 15, 25, and 50 mL Pb std working soln, 25.084(b)(2), to sep. 50 mL vol. flasks and dil. to vol. with 1N HCl (0, 0.2, 0.6, 1.0, 3.0, 5.0, and  $10.0 \mu\text{g Pb/mL}$ , resp.). Transfer 5 mL soln to polarographic cell, adjust to  $25 \pm 1^\circ$ , and bubble N thru soln 5 min. Polarograph between  $-0.2$  and  $-0.7$  v against Hg pool ref. electrode.

Peak potential for Pb at  $25^\circ$  is  $-0.45 \pm 0.05$  v. Plot  $\mu\text{g Pb/mL}$  cell soln against wave ht  $\times$  sensitivity factor.

**25.091****Determination**

Transfer 5 mL sample soln to polarographic cell, adjust to  $25 \pm 1^\circ$ , bubble N thru soln 5 min, and polarograph as in 25.090. Measure ht of wave whose potential corresponds to that of Pb and det. concn from newly prepd std curve or, preferably, by comparing wave ht of sample soln with that of std soln polarographed immediately before or after sample. Use latter method for greater accuracy, particularly when it is necessary to change instrument scale factor.

$C_u (\mu\text{g Pb/mL}) = (C_s \times WH_u \times SF_u) / (WH_s \times SF_s)$ , where subscripts s and u refer to std and sample, resp.;  $C = \mu\text{g Pb/mL}$  cell soln;  $WH$  = wave ht; and  $SF$  = sensitivity factor setting.

$$\text{ppm Pb} = (C_u \times 25) / \text{g sample.}$$

**25.092****Interference from Tin**

Sn polarographs at same peak potential as Pb. If presence of Sn is suspected, add 1 mL  $\text{NH}_4\text{OH}$  and 0.4 g tartaric acid to cell soln, bubble N thru soln, and polarograph as in 25.090. Treat std in same manner. Peak potential for Pb is 0.54 v. Sn does not polarograph at this peak potential.

**25.093 Atomic Absorption Spectrophotometric Methods**  
**for Earthenware—Official Final Action**

See 25.031–25.034.

**25.094 Rapid Screening Method for Earthenware**  
**Official First Action**

See 25.035–25.037.

**General Dithizone Method (17)**  
**Official Final Action**

**Sn and Bi Absent**

(Applicable to such materials as carbohydrates, cereals and cereal products, cacao and dairy products, feeds, meats, fish, plant material, fruit and fruit products, fresh vegetables, etc., and in general to all org. materials (except fats) in which no Sn and Bi are encountered. For products contg Sn (canned foods) or Bi, proceed as in 25.101–25.103.)

**25.095****Reagents**

(Caution: See 51.047.)

(a) *Lead std solns.*—(1) *Stock soln.*—2 mg Pb (3.197 mg  $\text{Pb}(\text{NO}_3)_2/\text{mL}$  in 1%  $\text{HNO}_3$ . Prep. from  $\text{Pb}(\text{NO}_3)_2$  purified as in

**25.062. (2) Working solns.**—Prep. as needed by dilg stock soln with 1%  $\text{HNO}_3$ .

(b) *Nitric acid*.—1%. Dil. 10 mL fresh, colorless  $\text{HNO}_3$  (sp gr 1.40) to 1 L with redistd  $\text{H}_2\text{O}$ . If acid has been redistd, boil off nitrous fumes before dilg.

(c) *"Ash-aid" soln.*—Dissolve 40 g  $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  and 20 g  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

(d) *Citric acid soln.*—Concd Pb-free soln. 1 mL = 0.5 g citric acid (reagent partially neutzd with  $\text{NH}_4\text{OH}$  during purification, **25.062**, fifth par.).

(e) *Diphenylthiocarbazone (dithizone)*.—Dissolve ca 1 g com. reagent in 50–75 mL  $\text{CHCl}_3$  and filter if insol. material remains. Ext in separator with four 100 mL portions metal-free (redistd)  $\text{NH}_4\text{OH}$  (1+99). (Dithizone passes into aq. phase to give orange soln.) Filter aq. exts into large separator thru cotton pledget inserted in stem of funnel. Acidify slightly with dil.  $\text{HCl}$  and ext pptd dithizone with two or three 20 mL portions  $\text{CHCl}_3$ . Combine exts in separator and wash 2 or 3 times with  $\text{H}_2\text{O}$ . Drain  $\text{CHCl}_3$  into beaker and evap. with gentle heat on steam bath, avoiding spattering as soln goes to dryness. Remove last traces of moisture by heating 1 hr at  $\leq 50^\circ$  in *vacuo*. Store dry reagent in dark in tightly stoppered bottle. Prep. reagent solns for extn to contain 100, 50, and 10 mg/L in freshly redistd  $\text{CHCl}_3$  (JAOAC **21**, 695(1938); **26**, 26(1943)) and store in dark at 5–10°. (Stock soln of dithizone in  $\text{CHCl}_3$  contg 1 mg/mL will keep long time and is convenient for use in making dilns.) Soln of 30 mg/L  $\text{CHCl}_3$  stored in dispensing app. is required for use in rapid method, **25.107**.

(f) *Ammonia-cyanide mixture*.—To 100 mL 10% recrystd,  $\text{PO}_4$ -free KCN (JAOAC **20**, 191(1937)) in 500 mL vol. flask, add enough redistd  $\text{NH}_4\text{OH}$  to introduce 19.1 g  $\text{NH}_3$ , and dil. to vol. with redistd  $\text{H}_2\text{O}$ . (Concn of redistd  $\text{NH}_4\text{OH}$  can be detd by sp gr or titrn.)

(g) *Pure metallic tin*.—Purest obtainable, such as NBS Sample No. 42. Granulate Sn as finely as possible by melting and pouring very slowly into  $\text{H}_2\text{O}$ . Det. Pb content as follows: Dissolve 1–2 g sample in  $\text{HBr}$  or  $\text{HCl}$  and volatilize Sn by evapg soln to dryness and treating with several 5 mL portions of the  $\text{HBr}$ -Br mixt., (h), evapg to dryness on steam bath after each treatment. Take up with 2–3 mL  $\text{HNO}_3$ , evap. to dryness to expel Br, and take up with ca 50 mL hot  $\text{H}_2\text{O}$ . Filter, and proceed as in **25.098** and **25.100**.

(h) *Hydrobromic acid-bromine mixture*.—To 250 mL 40% redistd  $\text{HBr}$  add 35 mL redistd liq. Br.

(i) *Sodium polysulfide soln.*—Dissolve 480 g  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  and 40 g  $\text{NaOH}$  in  $\text{H}_2\text{O}$ , add 16 g powd S, shake until S dissolves, filter, and dil. to 1 L.

(j) *Hydrochloric-citric acid soln.*—Add vol. reagent (d) equiv. to 50 g citric acid to 50 mL  $\text{HCl}$  and dil. to 250 mL.

(k) *Sodium oleate soln.*—10%. To 45 mL 30%  $\text{NaOH}$  soln and 400 mL  $\text{H}_2\text{O}$  in 1.5 L beaker, add slowly, while heating and stirring, 90 g (by difference from separator) oleic acid. Heat mixt. on steam bath until soap is entirely dissolved. (Small flocculent ppt of impurities may remain.) Cool, dil. to 1 L, mix, and filter.

(l) *Ammonia-cyanide-citrate soln.*—Dissolve 10 g phosphate-free KCN and 10 g citric acid in 250 mL  $\text{NH}_4\text{OH}$  (sp gr 0.90) and dil. to 1 L. Reagent is conveniently preserved in dispensing app. that causes min. volatilization of  $\text{NH}_3$ .

(m) *Washed filter paper*.—Soak 9 cm quant. papers overnight in 1%  $\text{HNO}_3$ . Wash with large vols  $\text{H}_2\text{O}$  on buchner to remove acid and any traces of Pb.

## 25.096

### Preparation of Sample (Ashing)

(Caution: See **51.025** and **51.028**.)

Accurately weigh representative sample of 5–200 g, depend-

ing upon amt sample available and expected Pb content, into suitable porcelain dish or casserole. Dry wet samples on steam bath or in oven. Add 2–5 mL "ash-aid" soln, (c), to products difficult to ash (meats), or to furnish ash bulk to low-ash products (candies, and jellies low in fruit content); mix well, and dry.

Char gelatin, carbohydrate foods such as jam, and other products that tend to swell excessively by carefully heating over burner. (Swelling can be controlled by playing small flame from glass jet over surface of material in dish, but metallic burner must not be used because of possible metallic contamination.) Do not let material ignite. Milk, candies, etc., may be charred without ignition by adding sample little at time to casserole heated over burner or hot plate. (Overhead radiant heater is often very convenient.) When samples are dry or charred, place in temp.-controlled furnace and raise temp. *slowly* to  $500^\circ$  without ignition.

If sample contains fat, "smoke" it away by heating long enough at ca  $350^\circ$ . Cover floor of furnace with piece of asbestos board or  $\text{SiO}_2$  plate so that sample receives most of its heat by radiation from sides and roof and not by conduction from hotter floor of furnace.

If furnace has automatic control, ash overnight at  $\leq 500^\circ$ . If sample is not completely ashed next morning or if day-time ashings at  $500^\circ$  are not proceeding satisfactorily, remove casserole, cool, and moisten char with 2–5 mL ash-aid. Dry contents of casserole past danger of spattering (no free liq.) and replace in furnace. If ashing is not complete or proceeding rapidly after 30 min, remove casserole, cool, and cautiously add 2–3 mL  $\text{HNO}_3$ . Dry, place in furnace, and continue ashing until practically C-free. Avoid excessive use of ash-aid, and particularly  $\text{HNO}_3$ , if sample still contains much intermixed C, because local overheating or deflagration may result, especially if much K is present in ash.

When clean ash is obtained, cool, cover casserole with watch glass, and cautiously add 15–20 mL  $\text{HCl}$ . Rinse down watch glass with  $\text{H}_2\text{O}$  and heat on steam bath. If *clear* soln is not obtained, evap. again to dryness and repeat addn of  $\text{HCl}$ . If insol. matter persists, evap.  $\text{HCl}$  and dehydrate  $\text{SiO}_2$  by heating to fumes with 5–10 mL 60%  $\text{HClO}_4$  (double distd preferred). If  $\text{HClO}_4$  is used, considerable  $\text{H}_2\text{O}$  (200 mL) may be necessary to completely dissolve  $\text{KClO}_4$  later, as when KCN is used in dithizone extn of Pb, **25.098**.

Dil. with  $\text{H}_2\text{O}$  and filter soln when necessary with suction thru fine fritted glass filter. Catch filtrate in 500 mL g-s erlenmeyer under bell jar. Leach insol. material on filter successively with few mL hot  $\text{HCl}$ , hot  $\text{HCl}$ -citric acid soln, and hot 40%  $\text{NH}_4\text{OAc}$  soln.

In certain instances take following special precautions:

(1) If amt of insol. material ( $\text{SiO}_2$ ) remaining on filter is abnormal, flush it into Pt dish with  $\text{H}_2\text{O}$ , evap., and treat residue with one or two 5 mL portions  $\text{HF}$ . Evap. to dryness, take up residue with  $\text{H}_2\text{O}$  and few drops of  $\text{HCl}$  or  $\text{HClO}_4$ , and add to bulk of ash filtrate.

(2) When ashing is of long duration, no ash-aid has been used, or natural ash is low with little ash bulk, Pb may be baked on dish. To remove this Pb, add few pellets (2–3 g) of  $\text{NaOH}$  and dissolve in few mL hot  $\text{H}_2\text{O}$ . Tilt dish so that sirupy soln completely wets that portion of interior originally occupied by sample; then heat short time on steam bath, but do not bring to dryness. (Overheating with concd  $\text{NaOH}$  may result in extg few  $\mu\text{g}$  Pb from casserole. Porcelain retains Pb to less extent than does  $\text{SiO}_2$  but may contain very small amts of Pb.) Take up residue with  $\text{H}_2\text{O}$  and add directly to filtrate. Finally rinse dish with few mL hot  $\text{HCl}$  followed by hot  $\text{H}_2\text{O}$ .

**25.097****Isolation of Lead: Principle**

Method **25.098**, while rapid and convenient, is limited to those materials that, with aid of citric acid, yield clear ammoniacal soln required for quant. extn of Pb with dithizone. Pb is readily occluded by many alk. ppts (Mg and Ca phosphates, Al and Fe hydroxides and silicates). Many food materials may be handled in this way because the naturally occurring amts of these substances are not excessive. However, some materials contain more of these substances than can be kept in soln under alk. conditions with any reasonable amt of citric acid (JAOAC **26**, 26(1943)). In these cases proceed as in **25.099**. Difficulty of ammoniacal pptn may sometimes be overcome by limiting sample size in cases where sampling is no problem.

**25.098****Dithizone Extraction**

(Applicable to most carbohydrates and cereal foods, fruit and fruit products, milk, fresh vegetables, plant materials, etc.)

Transfer ash soln to 300 mL short-stem separator and add citric acid reagent, (d), equiv. to 10 g citric acid. Make slightly alk. to litmus with  $\text{NH}_4\text{OH}$ , keeping soln cool, and let stand 1–2 min. If ppt forms, redissolve with HCl and isolate Pb as in **25.099**. If no ppt forms, add 5 mL 10% KCN soln (more may be necessary if large amts of Zn, Cu, Cd, etc., are present), and check pH of soln by adding drop of *thymol blue soln* and observing color of drop (pH should be  $\geq 8.5$ , blue-green to blue with *thymol blue*).

If ash was highly colored with Fe, keep pH of soln comparatively low, because pH of  $\geq 10$  in presence of Fe may cause oxidn of dithizone. Immediately ext with 20 mL portions dithizone reagent, using more dil. solns unless exceptionally large amts of Pb are present. Shake 20–30 sec, let layers sep., and note color of  $\text{CHCl}_3$  phase. (Pb dithizone complex is red, but color may be masked by excess green dithizone, giving intermediate hues of purple and crimson. Color of  $\text{CHCl}_3$  ext gives first indication of amt of Pb present, and progress of extn can be followed by noting color of successive exts.)

Drain exts directly into small separator contg 25 mL 1%  $\text{HNO}_3$ , (b). When extn is complete, shake combined exts in smaller separator and drain green dithizone layer into another separator contg addnl 25 mL portion 1%  $\text{HNO}_3$ . Shake, let layers sep., and discard  $\text{CHCl}_3$  fraction. Filter acid exts contg Pb in succession thru small pledget of wet cotton inserted in stem of small funnel, into 50 mL flask or g-s graduate, using second acid ext to rinse separator in which first acid extn was made. (This procedure removes  $\text{CHCl}_3$  globules.) Make up any slight deficiency in vol. with 1%  $\text{HNO}_3$  and mix. Proceed as in **25.100**.

**25.099****Sulfide Separation**

(Applicable to all products and usually necessary in case of cacao products, tea, sardines, and all food products contg high proportion of alk. earth phosphates, especially those of Mg, which promote formation of ppts in ammoniacal citrate solns.)

Cool acid soln of ash, add citric acid soln, (d), equiv. to 10 g citric acid, and adjust to pH 3.0–3.4 (bromophenol blue) with  $\text{NH}_4\text{OH}$ . If enough Fe is present to color soln strongly, make final adjustment with help of spot plate. (Phosphates pptd by local action of  $\text{NH}_4\text{OH}$  may usually be redissolved by shaking and cooling.) If amt of Pb is small, add 5–10 mg pure  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  to soln to act as coprecipitant. Ppt sulfides by passing in  $\text{H}_2\text{S}$  until soln is satd (3–5 min). (Caution: See **51.059**.) Immediately filter with suction into flask in bell jar (fine fritted glass filter is preferred).

Dissolve sulfides, without previous washing, with 5 mL hot  $\text{HNO}_3$ , drawing soln thru into original flask; wash with hot  $\text{H}_2\text{O}$ , stopper, shake, and boil to remove  $\text{H}_2\text{S}$ . Transfer to 200 mL

separator, add citric acid soln equiv. to 5 g citric acid, make ammoniacal, ext, and det. Pb as in **25.098** and **25.100(a)** or (b).

**25.100****Colorimetric Dithizone Determination (18)**

(Pb 0.001–0.200 mg)

Limiting factor in detn of minute amts of Pb by colorimetric dithizone method is size of reagent blank, particularly when amts of Pb of order of 1–5  $\mu\text{g}$  are being detd. With special care in purification of reagents and by use of carefully cleaned Pyrex ware, including separators, it is possible to reduce reagent blank to  $\leq 1 \mu\text{g}$ . Owing to Pb-bearing dust, vapors, etc., it is necessary to expose blank detn in furnace or on steam bath for same length of time as sample is exposed, and to use exactly same amts of reagents (even  $\text{H}_2\text{O}$ ) for blank and actual detns.

Pb is extd from aq. soln, under std conditions of vol. and pH, with definite vol. of  $\text{CHCl}_3$  soln of dithizone of std concn. Optimum pH of operation is 9.5–10.0. Dithizone strengths are so chosen that excess dithizone is always present in reaction mixt. Pb is brought into  $\text{CHCl}_3$  phase in form of red complex, and uncombined green dithizone partitions between aq. and  $\text{CHCl}_3$  phases and modifies color of ext according to relative amts of Pb and dithizone. Thus, series of colors from red to green may be arranged with intermediate crimsons, purples, and blues. Vols and strengths of  $\text{CHCl}_3$  solns depend upon Pb range it is desired to cover and are so chosen as to give same general color progression from red to green for each range. Limiting range increases accuracy at expense of flexibility. Colors produced with std amts of Pb furnish basis for quant. estn by comparison. Vols and concns of std dithizone for various ranges are as follows when 1 cm cell is used:

Pb Ranges $\mu\text{g}$	Concn mg/L	Volume mL
1–10	8	5
0–50	10	25
0–200	20	40

See Anal. Chem. **19**, 684(1947), for modification operated at pH 11.5.

(a) *Simple color matching*.—Prep. 10 stds covering in equal steps the desired concn range, as follows: Use std Pb soln, **25.095(a)**, in 1%  $\text{HNO}_3$ , 1 mL of which equals some simple fraction or multiple of 1  $\mu\text{g}$  Pb. Measure vols representing various steps of range into series of separators and add 1%  $\text{HNO}_3$  so that total vol. is always 50 mL. (Add acid first so that Pb soln is not lost around stopcock of separator.) Add 10 mL  $\text{NH}_3$ -cyanide mixt., (f), and mix. Resultant pH will be ca 9.7. Immediately add appropriate vol. std dithizone soln, which depends on range to be covered (see table), and shake 1 min. Drain lower layers into series of tubes or vials and arrange in order. For lower ranges, i.e.,  $< 20 \mu\text{g}$  Pb, matching is best done by viewing longitudinally in small flat-bottom vials ca 75 mm long. For higher ranges, 20–50  $\mu\text{g}$  and above, depth of column must be reduced, and matching is conveniently done by viewing transversely in Nessler tubes of matched diam., because even pure dithizone solns appear red by transmitted light if concn or depth of column is increased beyond certain point. If stds are kept covered when not in use, they should last  $\geq 1$  day.

For detn, place aliquot part, or entire amt, of the 50 mL 1%  $\text{HNO}_3$  in which Pb has been isolated, **25.098** or **25.099**, in separator, and if aliquot is taken, dil. to 50 mL with 1%  $\text{HNO}_3$ . Add 10 mL  $\text{NH}_3$ -cyanide mixt., (f), and mix. Immediately develop color by shaking 1 min with proper amt std dithizone soln. Drain lower layer into tube or vial similar to those used with stds and compare. If range is exceeded, repeat with smaller aliquot or re-ext with excess dithizone before draining from separator, isolate once more in 50 mL 1%  $\text{HNO}_3$  reagent, and compare with stds

covering higher range. Interpolation between steps of various ranges should be easily made.

If aliquot of the 50 mL 1%  $\text{HNO}_3$  in which Pb has been isolated is taken, subtract only corresponding amt of total reagent blank from amt of Pb found.

(b) *Photometric methods*.—Absorption spectra of the 2 components in dithizone ext (Pb dithizone complex and free dithizone) show marked difference in ability to absorb 510 nm light, red Pb complex absorbing strongly and green dithizone transmitting freely. Thus, when absorption of light of this wavelength is detd photometrically, linear relationship is observed between amt of Pb and A. In making measurements, spectrophtr set at this wavelength or photometer equipped with blue-green filter centered at about this point can be used.

Stdze dithizone solns as follows: Using appropriate vols and concns of solns specified for various ranges (see above) in separators, prep. std colors as in visual color-matching procedure, satg std Pb and 1%  $\text{HNO}_3$  solns with clear  $\text{CHCl}_3$  before use, and thereby eliminating differences in vol. of ext between stds and unknowns. (It is unnecessary to prep. full 10 steps of the range, and number of stds may be limited to 5 or 6.) Develop colors by shaking separators 1 min, let stand few min, and filter exts thru specially prepd papers, (m). (Fitting 9 cm paper directly into mouth of 50 mL Pyrex beaker eliminates need of funnel in filtering operation.) Fill cell with filtered exts and det. A for various steps of range.

Plot against amt of Pb to obtain std curve for particular lot of dithizone. Preferably calc. slope of line connecting std points and intercept of line on A axis, making calcn by least squares method as in *Definitions of Terms and Explanatory Notes*, Item (24).

Det. Pb content of unknown falling within the range of detg A, using std dithizone and same cell with which std readings were made, and calc. Pb from equation  $X = (Y/b) - (a/b)$ , using values of a and b detd previously. If protected from evapn and direct sunlight, std factors of dithizone solns should not change appreciably for  $\geq 1$  month (JAOAC 21, 695(1938); 26, 26(1943)).

For actual detn proceed as in (a), except to filter ext thru prepd papers before photometric measurement. Det. A, using stdzd dithizone with same cell used in making std curve, and read amt of Pb from this std curve or calc. from factor of dithizone soln. If range is exceeded, repeat with smaller aliquot, or re-ext and repeat with dithizone stdzd to cover higher range. If aliquot of the 50 mL 1%  $\text{HNO}_3$  in which Pb has been isolated is taken, subtract only corresponding amt of total reagent blank from amt of Pb found.

## 25.101

### Interferences

Interferences in colorimetric dithizone method are limited by use of KCN to  $\text{Sn}^{+2}$ , Bi, and Tl. Rarity of Tl makes its interference unlikely in ordinary work, and no method of removal is given (JAOAC 26, 26(1943)). Dithizone itself is destroyed by strong oxidizing agents, such as free halogens and large amts of ferric Fe, under conditions of dithizone extn of Pb.

## 25.102

### Removal of Tin

(Caution: See 51.028, 51.047, and 51.059.)

Sn becomes problem in analysis of canned foods; in amts  $>150$  ppm it will usually appear in ash soln as milky suspension of  $\text{SnO}_2$ . It must be dissolved to facilitate filtration and to release occluded Pb. Quantities of Sn of this order may cause trouble by pptg under conditions of dithizone extn of Pb, 25.098.

Two methods for elimination of larger amts of Sn are given: (a) Volatilization as  $\text{SnBr}_4$  from acid soln of ash, and (b) leaching mixed sulfides with warm Na polysulfide soln, when sulfide

method of isolation, 25.099, has been applied. These methods may not eliminate Sn completely. Stannic Sn is not extd with dithizone, and as small amts of residual Sn will be in  $\text{Sn}^{+4}$  form after application of either (a) or (b), final isolation of Pb by dithizone extn will eliminate Sn completely.

In general, amts  $<100$  mg should not interfere in colorimetric dithizone methods of Pb detn provided Sn is in  $\text{Sn}^{+4}$  form and preliminary isolation with dithizone is made; hence, this method of isolation should be applied wherever possible.

(a) *Volatilization as  $\text{SnBr}_4$  from acid soln of ash*.—After almost C-free ash is obtained, 25.096, add 15–20 mL 40% redistd HBr. If nitrates were used as ash aids, cover casserole with watch glass and heat on steam bath until Br evolution diminishes; then rinse watch glass with  $\text{H}_2\text{O}$  and bring to boil to complete expulsion of Br. (This process destroys undecomposed nitrates.) Add more HBr if necessary to dissolve ash, and examine solns for clearness. If there is insol. residue of  $\text{SnO}_2$ , add 50–100 mg pure Sn, (g), to simmering HBr soln of ash and let it dissolve. (Metallic Sn is best agent to bring ignited  $\text{SnO}_2$  into soln. To be effective, ash soln must be in reduced state.  $\text{Fe}_2\text{O}_3$  sometimes becomes "noble" during ashing and dissolves with difficulty, but treatment with metallic Sn also brings it into soln. Treatment with Sn is necessary only with contents of badly corroded cans.)

When soln of ash is free from milkiness due to  $\text{SnO}_2$ , add 20 mL 60%  $\text{HClO}_4$  (double distd preferred), oxidize mixt. with few mL HBr-Br mixt., (h), and then add addnl 15 mL of the reagent portionwise, while soln is evapd to incipient fumes of  $\text{HClO}_4$  (ca  $150^\circ$ ) on hot plate. Repeat with addnl 10 mL portion HBr-Br mixt. if  $>100$  mg Sn was used to dissolve ash. (Hot  $\text{HClO}_4$  helps keep ash salts in soln and with Br holds Sn as volatile  $\text{SnBr}_4$ .) When HBr and Br are completely volatilized, cool, and take up with hot  $\text{H}_2\text{O}$  (200 mL may be necessary if much  $\text{KClO}_4$  is present). Filter off any small amts of dehydrated  $\text{SiO}_2$ , ext residue twice with 5 mL hot HCl-citric acid reagent, (j), and hot  $\text{H}_2\text{O}$ , treat dish if necessary with NaOH as in 25.096(2), and isolate Pb by dithizone extn as in 25.098, or by sulfide sepn, 25.099, finally detg Pb as in 25.100 (a) or (b).

(b) *With sodium polysulfide*.—(Recommended for routine work on canned foods.)

Isolate Pb by sulfide pptn, 25.099, filter, and wash flask and filter with 3–6 portions of ca 5 mL each of warm Na polysulfide soln, (i). (Sn, As, and Sb sulfides are dissolved; CuS may be partially dissolved and repptd in filtrate.) Wash flask and residual sulfides several times with 3%  $\text{Na}_2\text{SO}_4$  soln adjusted to pH 3.0–3.4 and satd with  $\text{H}_2\text{S}$ , and proceed as in 25.099, beginning "Dissolve sulfides, without previous washing, . . ." When ash contains much Sn, as when metallic Sn has been added to dissolve insol. metallic oxides, sulfide ppt will be so bulky as to be difficult to handle, and it will be necessary to use volatilization method (a) before sulfiding. For colorimetric dithizone detn of Pb, ext  $\text{HNO}_3$  soln of dissolved sulfides and proceed as in 25.099 and 25.100(a) or (b).

## 25.103

### Detection and Removal of Bismuth

(Caution: See 51.026, 51.047, 51.050, and 51.078.)

(a) *By dithizone at pH 2.0 after preliminary dithizone extraction at pH 8–11 (19)*.—(This method completely removes small amts of Bi.)

Ext metals from  $\text{CHCl}_3$  dithizone ext with 50 mL 1%  $\text{HNO}_3$  as in 25.098. Adjust acid ext to pH 2.0 (metacresol purple indicator) with 5%  $\text{NH}_4\text{OH}$  soln and shake vigorously ca 1 min with 10 mL  $\text{CHCl}_3$  soln of dithizone (200–250 mg/L). Let layers sep., and if  $\text{CHCl}_3$  ext is orange red to red (Bi), drain off and ext with addnl 10 mL dithizone soln. If shades of green or purple are visible, indicating excess dithizone, drain  $\text{CHCl}_3$  ext and ext aq. phase

once more with 5 mL dithizone soln (shaking should be prolonged (3–5 min) to ensure complete extn of Bi). Continue extrns until dithizone ext remains pure green. Adjust aq. soln to pH 8.5 with  $\text{NH}_4\text{OH}$ , add KCN, and ext with dithizone as in **25.098**. Det. Pb colorimetrically as in **25.100(a)** or **(b)**.

(Method of Bambach and Burkey (Ind. Eng. Chem., Anal. Ed. **14**, 904(1942)) seps small amts of Bi from Pb by shaking out  $\text{CHCl}_3$  soln of their mixed dithizonates with aq. soln buffered at pH 3.4; Bi remains as dithizonate in  $\text{CHCl}_3$  phase, while Pb enters aq. phase and can be sepd Bi-free. Only slight excess of free dithizone should be present in  $\text{CHCl}_3$  mixt. of dithizonates, otherwise Pb does not strip out completely. System of photometric detection and evaluation of Bi interference has also been outlined (JAOAC **26**, 26(1943)).

**(b) From acid soln of sulfides.**—(Intended for small amts of Bi, particularly when sulfide sepn may be necessary.) Dissolve mixed sulfides, **25.099**, with hot  $\text{HNO}_3$  and sep. Bi and Pb as in **(a)**.

**Special conditions.**—(Intended for products contg large amts of Bi.) Dissolve inorg. Bi compds directly in HBr-Br, **(h)**. Prep. org. Bi compds or Bi prepn mixed with org. matter contg little ash, as in **25.096**, and dissolve residue in HBr-Br. If sample contains org. matter with appreciable ash material other than Bi compds, proceed as in **25.096** or **25.105**, apply sulfide sepn, **25.099**, and dissolve mixed sulfides in  $\text{HNO}_3$ . Evap.  $\text{HNO}_3$  soln of sulfides to dryness in porcelain dish and treat with small portions HBr-Br mixt. Evap. contents of dish contg Bi dissolved in HBr-Br, after any of above methods of prepn, on steam bath to volatilize Sn and to convert other metals to bromides. Evap. to dryness, place in furnace with temp. control, and raise temp. gradually to  $300^\circ$ . ( $\text{AsBr}_3$  and  $\text{SbBr}_3$  volatilize first at  $100^\circ$  or above;  $\text{BiBr}_3$  volatilizes as dense orange fumes at  $300^\circ$ .) After 5 min, or when fumes cease, remove dish, cool and treat again with small portions HBr-Br. Again evap. to dryness and heat addnl 5 min at  $300$ – $325^\circ$  ( $\text{PbBr}_2$  does not volatilize appreciably at  $<350^\circ$ ). Remove dish, cool, and dissolve residue in hot  $\text{HNO}_3$ . Proceed with removal of last traces of Bi at pH 2.0 and det. Pb as in **(a)**.

### Special Methods of Sample Preparation

#### 25.104

#### Solution in Acids

(Applicable to chemicals sol. in  $\text{H}_2\text{O}$  or acid, e.g., phosphates, sulfates, etc., and org. products of type of tartrates and citrates; *Caution: See 51.059.*)

Dissolve 5–100 g sample, according to its nature and amt of Pb expected, in HCl in 400 mL beaker. With Ca phosphates, use 10–50 g. Dissolve in smallest practicable vol. of soln by warming and adding alternately small amts of hot  $\text{H}_2\text{O}$  and HCl. Filter soln with suction (fritted glass preferred) into beaker or flask under bell jar and leach any residue with 10–25 mL hot HCl-citric acid, **(j)**, followed by 10–25 mL hot 40%  $\text{NH}_4\text{OAc}$  soln. Rinse beaker and filter with hot  $\text{H}_2\text{O}$  and cool soln.

Proceed as in **25.098**. If interfering ppt forms, again acidify and isolate Pb by sulfide pptn, **25.099**. If it is difficult to obtain clear soln with Ca phosphates at pH 3.0–3.4 (sulfide ppt may be contaminated with excessive phosphates), redissolve ppt, add more citric acid soln, **(d)**, readjust pH, and reppt sulfides; or make one sulfide pptn, dissolve sulfides in hot  $\text{HNO}_3$ , boil off  $\text{H}_2\text{S}$ , and ext Pb with dithizone, **25.098**. Sometimes difficulty due to ppt formation in **25.098** can be avoided by using smaller sample for extn and colorimetric detn. If Sn or Bi is suspected, remove by methods described in **25.102** and **25.103**. Finally det. isolated Pb colorimetrically, **25.100**.

#### 25.105

#### Complete Digestion

(Applicable to most food or biological products; with difficulty to fats and oils, oily products, etc. *Caution: See 51.011 and 51.078.*)

Digest representative sample in Kjeldahl flask as in **25.008**. Distil As, if desired, as  $\text{AsCl}_3$ , **25.009**. If As is not to be distd, add 100 mL  $\text{H}_2\text{O}$  and enough HCl to flask to dissolve any  $\text{CaSO}_4$  in residue. Filter on fritted glass filter, pulverizing any insol. residue (anhyd.  $\text{SiO}_2$  or  $\text{BaSO}_4$ ) with flat-end stirring rod. Dissolve any  $\text{PbSO}_4$  in flask and leach residue on filter with 10–20 mL hot HCl-citric acid soln, **(j)**, followed by 10–20 mL hot 40%  $\text{NH}_4\text{OAc}$ . Finally rinse both flask and filter with hot  $\text{H}_2\text{O}$ . Isolate Pb by dithizone, **25.098**, or sulfide pptn, **25.099**, methods. (In general, sulfide method is preferable, especially when  $\text{BaSO}_4$  or excessive  $\text{CaSO}_4$  is present, as insol. sulfates readily occlude Pb.) If Bi and Sn are present, remove them as in **25.102** or **25.103**. After isolation, det. Pb by colorimetric method, **25.100**.

#### Rapid Method Restricted to Apples and Pears Official Final Action

(Efficiency of 95% expected)

(For rapid detn of Pb spray residue on apples and pears; ppm  $\times 0.007$  = grains/lb; (grains/lb)  $\times 143$  = ppm)

#### 25.106

#### Preparation of Sample

Weigh  $\geq 10$  units and pull or cut out stems with narrow-blade knife, cutting no more of flesh than necessary. Trim off sepals (dried residue of blossom) and discard sepals and stems. To 25 mL 30% NaOH soln in 600 mL beaker, add 175 mL  $\text{H}_2\text{O}$  and 25 mL Na oleate soln, **(k)**, and bring to gentle boil. Have ready in wash bottle 250 mL hot  $\text{HNO}_3$  (2+98) or hot HCl (3+97). (Reasonably accurate figure for  $\text{As}_2\text{O}_3$  can be obtained by using the HCl rinse and applying Gutzeit As detn, **25.020\***, to portion of filtrate, after acidifying part of the 500 mL alk. strip soln with  $1/10$  vol. HCl instead of  $\text{HNO}_3$  (see later in this section). Rapid method for F, **25.059**, likewise specifies HCl rinse and acidification.)

Impale each fruit in turn upon pointed glass rod; immerse in the alk. soln, with occasional rotation, until skin begins to check; then remove to large funnel inserted in 500 mL vol. flask and rinse with stream of the hot acid, being careful to flush out stem and calyx ends thoroly. When all fruit has been so treated, cool alk. soln and add it thru funnel to acid soln in flask. Rinse beaker and funnel with any remaining acid and with  $\text{H}_2\text{O}$ , using entire 250 mL rinse acid. Cool, and dil. to vol.

In dry 200 mL erlenmeyer place exactly 10 mL  $\text{HNO}_3$  (10 mL HCl for As or F). Thoroly mix contents of vol. flask and immediately add 100 mL to acid in erlenmeyer while swirling vigorously. Filter on rapid paper. If first portion of filtrate is cloudy, refilter until clear. Det. Pb as in **25.107** or **25.108**.

(See JAOAC **26**, 150(1943)) for details of churn-type washer for removing Pb spray residues from apples and pears.)

#### 25.107

#### Determination with Nessler Tubes

(At least 15 tall-form tubes matched for uniformity in color and diam. are necessary. *Caution: See 51.050.*)

**(a) Stds.**—To each of two 1 L vol. flasks add 47.5 mL 30% NaOH soln. If  $\text{HNO}_3$  was used in rinsing and acidification, **25.106**, add 100 mL  $\text{HNO}_3$  to each flask. If HCl (3+97) was used in rinsing, add 91 mL  $\text{HNO}_3$  and 13.6 mL HCl to each flask. Do not mix in the acids unless solns are cold and dil. To one flask add stock reagent, **(a)**, equiv. to 25.45 mg Pb. Mark this flask "std" and other "blank." Dil. both solns to vol. at room temp. and mix. These 2 solns contain reagents as they occur in acidified

and filtered sample soln. The "std" is equiv. in Pb content to acidified soln from sample of 1400 g carrying Pb load (removable by "stripping" operation) of 10 ppm. By combination of the 2 solns in suitable proportions, equiv. of any Pb load from 0 to 10 ppm may be obtained.

Std tubes made up in intervals corresponding to 1.0 ppm may be interpolated to 0.5 ppm. Following table gives vols of "std" and "blank" to be added to Nessler tubes for each interval; measure into tube by burets:

Pb ppm	"Standard" mL	"Blank" mL
0.0	0.0	10.0
1.0	1.0	9.0
2.0	2.0	8.0
3.0	3.0	7.0
4.0	4.0	6.0
5.0	5.0	5.0
6.0	6.0	4.0
7.0	7.0	3.0
8.0	8.0	2.0
9.0	9.0	1.0
10.0	10.0	0.0

Working with 1 tube at time, add 10 mL  $\text{NH}_3$ -cyanide-citrate soln, (I), to each tube followed by 30 mL std dithizone soln, 30 mg/L, **25.095(e)**. Shake vigorously 1 min and let sep. The pH of aq. phase should be ca 9.4 regardless of whether HCl or  $\text{HNO}_3$  is used in rinsing. Stopper each std tube securely with new cork stopper. It is unnecessary to make up entire series of stds if only portion of range, e.g. 5.0–10.0 ppm, is of quant. interest.

(b) *Comparison*.—Transfer 10 mL portions of clear filtrate from **25.106** to each of 3 Nessler tubes. First add 10 mL  $\text{NH}_3$ -cyanide-citrate soln, (I), to each tube; to one tube add 30 mL std dithizone soln, 30 mg/L, **25.095(e)**, and to other 2 tubes 30 mL clear  $\text{CHCl}_3$ . Shake vigorously 1 min and let sep. With tube of clear  $\text{CHCl}_3$  backing sample tube (contg the dithizone) and 1 sample tube contg  $\text{CHCl}_3$  backing each of 2 std tubes, compare color in lower layer of sample with that of stds, looking thru tubes at right angles to their lengths toward strong diffused light. (Comparator box similar to boxes used in colorimetric pH measurements but of larger size is convenient. When working with apple strip solns, slight turbidity is produced in sample tube, which slightly changes color observed. To compensate for this effect, same turbidity is introduced in field of view of std tubes made up exactly as sample, except that  $\text{CHCl}_3$  is substituted for the dithizone soln.)

If color produced by sample is redder than 10 ppm std, repeat with smaller aliquot of filtrate, dilg to 10 mL with "blank" soln. If, for example, 5 mL aliquot is taken, indicated reading must be doubled. After match is obtained, calc. result to basis of 10 mL aliquot and 1400 g sample.

## 25.108

### Determination with Photometer

(This method is suitable for photometric measurement of "mixed color," **25.100(b)**. Changes in **25.107** are introduced here to prevent formation of colors too dense for measurements. Use 5 mL instead of 10 mL aliquots of acidified wash soln, **25.106**. *Caution: See 51.050.*)

(a) *Stds*.—Measure following proportions of "std" and "blank" solns, **25.107(a)**, into separators:

Pb ppm	"Standard" mL	"Blank" mL
0.0	0.0	10.0
2.0	1.0	9.0
4.0	2.0	8.0
6.0	3.0	7.0
8.0	4.0	6.0
10.0	5.0	5.0

Add 10 mL  $\text{NH}_3$ -cyanide-citrate soln, (I), and working with 1 separator at time, immediately develop color by shaking 1 min with 50 mL pure dithizone soln of 10 mg/L strength. Let stand few min to cool, filter  $\text{CHCl}_3$  layers thru specially washed papers, (m), and fill cell of appropriate length (1 cm is convenient). Det. A and plot against ppm Pb to obtain std curve.

(b) *Comparison*.—Place appropriate size aliquot of acidified strip soln in separator and dil. to 10 mL with "blank" soln. Add 10 mL  $\text{NH}_3$ -cyanide-citrate soln, (I), and ext with 50 mL 10 mg/L std dithizone soln. Let stand few min to cool, filter, and read as above. Det. amt of Pb from std curve prepd as in (a) and calc. to basis of 5 mL aliquot and 1400 g sample.

## 25.109 MANGANESE—OFFICIAL FINAL ACTION

See **3.018** or **22.036**★.

### MERCURY

#### Flameless Atomic Absorption Method (20) Official Final Action

(Rinse all glassware before use with  $\text{HNO}_3$  (1+9). *Caution: See 51.019, 51.026, 51.028, 51.030, and 51.079.*)

## 25.110

### Apparatus

(a) *Atomic absorption spectrophotometer*.—Instrumentation Laboratory, Inc., 113 Hartwell Ave, Lexington, MA 02173, Model 153 (or successors), or equiv. Equipped with Hg hollow cathode lamp and gas flow-thru cell (Fig. **25.02**), 25 (id)  $\times$  115 mm with quartz windows cemented in place. *Operating conditions*: Wavelength 253.7 nm, slit width 160  $\mu\text{m}$ , lamp current 3 ma, and sensitivity scale 2.5.

(b) *Diaphragm pump*.—Neptune Dyna-Pump, or equiv. Coat diaphragm and internal parts of pump with acrylic-type plastic spray. Use 16 gage Teflon tubing for all connections.

(c) *Water condenser*.—12–18 (id)  $\times$  400 mm borosilicate, 24/40  $\text{F}$  joint, modified to hold 6 mm Raschig rings. Fill condenser with Raschig rings to ht of 100 mm; then place 20 mm layer of 4 mm diam. glass beads on top of rings.

(d) *Gas inlet adapter*.—24/40  $\text{F}$  (Kontes Glass Co. No. K-181000).

(e) *Digestion flask*.—250 mL flat-bottom boiling flask with 24/40  $\text{F}$  joint.

## 25.111

### Reagents

(a) *Reducing soln*.—Mix 50 mL  $\text{H}_2\text{SO}_4$  with ca 300 mL  $\text{H}_2\text{O}$ . Cool to room temp. and dissolve 15 g NaCl, 15 g hydroxylamine sulfate, and 25 g  $\text{SnCl}_2$  in soln. Dil. to 500 mL.

(b) *Diluting soln*.—To 1 L vol. flask contg 300–500 mL  $\text{H}_2\text{O}$ , add 58 mL  $\text{HNO}_3$  and 67 mL  $\text{H}_2\text{SO}_4$ . Dil. to vol. with  $\text{H}_2\text{O}$ .

(c) *Magnesium perchlorate*.—Drying agent placed in filter flask (Fig. **25.02**). Replace as needed. (*Caution:  $\text{Mg}(\text{ClO}_4)_2$  is explosive when in contact with org. substances.*)

(d) *Mercury std solns*.—(1) *Stock soln*.—1000  $\mu\text{g}/\text{mL}$ . Dissolve 0.1354 g  $\text{HgCl}_2$  in 100.0 mL  $\text{H}_2\text{O}$ . (2) *Working soln*.—1  $\mu\text{g}/\text{mL}$ . Dil. 1 mL stock soln to 1 L with 1N  $\text{H}_2\text{SO}_4$ . Prep. fresh daily.

## 25.112

### Determination

Weigh 5.0 g sample into digestion flask; add 25 mL 18N  $\text{H}_2\text{SO}_4$ , 20 mL 7N  $\text{HNO}_3$ , 1 mL 2% *Na molybdate soln*, and 5–6 boiling chips. Connect condenser (with  $\text{H}_2\text{O}$  circulating thru it) and apply gentle heat ca 1 hr. Remove heat and let stand 15 min. Add 20 mL  $\text{HNO}_3\text{-HClO}_4$  (1+1) thru condenser. Turn off  $\text{H}_2\text{O}$  circulating thru condenser and boil vigorously until white fumes appear in flask. Continue heating 10 min.

★ Surplus method—see inside front cover.

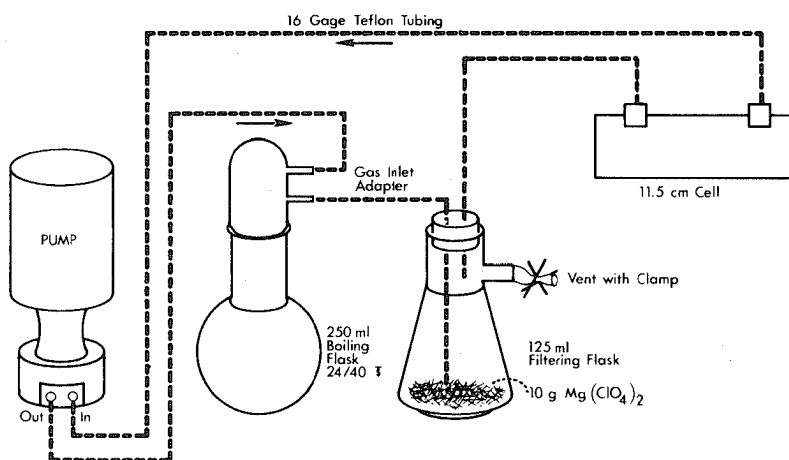

FIG. 25:02—Apparatus for flameless atomic absorption analysis

Cool. Cautiously add 10 mL  $\text{H}_2\text{O}$  thru condenser while swirling liq. in flask. Again boil soln 10 min. Remove heat and wash condenser with three 15 mL portions  $\text{H}_2\text{O}$ .

Cool soln to room temp. Completely transfer digested sample with  $\text{H}_2\text{O}$  to 100 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . Transfer 25.0 mL aliquot from each sample to another digestion flask. Adjust vol. to ca 100 mL with dilg soln, (b).

Adjust output of pump to ca 2 L air/min by regulating speed of pump with variable transformer. Connect app. as in Fig. 25:02, except for gas inlet adapter. With pump working and spectrophtr zeroed, add 20 mL reducing soln to dild aliquot. Immediately connect gas inlet adapter and aerate ca 3 min. (Adjust aeration time to obtain max.  $A$ .) Record  $A$ , disconnect pressure on "out" side of pump, and open vent on filter flask to flush system.

Prep. reagent blank and std curve by adding 0, 0.2, 0.4, 0.6, 0.8, and 1.0  $\mu\text{g}$  Hg to series of digestion flasks. To each flask add 100 mL dilg soln. Finally, add reducing soln and areate stds as for sample.

Plot std curve from least squares linear regression of  $A$  against  $\mu\text{g}$  Hg. (See "Definitions of Terms and Explanatory Notes," item (24), or use calculator which performs linear regression.) Det.  $\mu\text{g}$  Hg in aliquot from curve. If  $\mu\text{g}$  Hg detd falls outside range of calibration, repeat detn with smaller aliquot of sample soln to bring  $\mu\text{g}$  Hg into region of std curve. From size of aliquot used, det. total  $\mu\text{g}$  Hg in original sample.

$$\text{ppm Hg} = \mu\text{g Hg/g sample.}$$

#### Alternative Method for Fish (21)—Official Final Action

(Rinse all glassware before use with  $\text{HNO}_3$  (1+9). Caution: See 51.019, 51.026, 51.030, and 51.079.)

#### 25.113

#### Apparatus

See 25.110(a), (b), (e), and in addn:

(a) *Boiling stones*.—6–8 mesh (SGA Scientific Inc., No. D-7325).

(b) *Gas inlet adapter*.— $\text{\text{K}}$  24/40 (Kontes Glass Co., No. K-181000). Cut off end of glass tube which extends downward from adapter and affix gas dispersion tube with fritted cylinder (Corning Glass Works, No. 39533, porosity 12C).

(c) *Trap*.—Construct from cut off bulb of 15 mL pipet and place between digestion flask and cell, replacing flask of Fig. 25:02, to trap overflow.

(d) *Water condenser*.—12–18 (id)  $\times$  300 mm Liebig condenser with  $\text{\text{K}}$  24/40 joint. Modify by making indentations in glass between lower std taper and  $\text{H}_2\text{O}$  jacket with pointed C rod. Indent glass to hold 6 mm Raschig rings. Add 8–10 rings to condenser and cover with  $\frac{1}{8}$ " (3.17 mm) id glass helices (SGA Scientific Inc., No. JD-5360) to ht of 90 mm.

#### 25.114

#### Determination

Weigh 5.0 g (wet wt) thoroly mixed fish sample into digestion flask, 25.110(e). Rinse neck of flask with  $<5$  mL  $\text{H}_2\text{O}$ , if necessary. Add ca 20 boiling stones, (a), 10–20 mg  $\text{V}_2\text{O}_5$ , and 20 mL  $\text{H}_2\text{SO}_4$ - $\text{HNO}_3$  (1+1). Quickly connect flask to condenser, (d), and swirl to mix. Circulate cold  $\text{H}_2\text{O}$  thru condenser during digestion. Apply sufficient heat (luminous flame is suitable) to produce low initial boil (ca 6 min) and finish digestion with strong boil (ca 10 min). Swirl flask intermittently during digestion. No solid material should be apparent except for globules of fat after ca 4 min.

Remove flask from heat and wash condenser with 15 mL  $\text{H}_2\text{O}$ . Add 2 drops 30%  $\text{H}_2\text{O}_2$  thru condenser and wash into flask with 15 mL  $\text{H}_2\text{O}$ . Cool digested fish soln to room temp. by placing flask, still connected to condenser, in beaker of  $\text{H}_2\text{O}$ . Disconnect flask, rinse ground joint with  $\text{H}_2\text{O}$ , and quant. transfer digest to 100 mL vol. flask. Ignore solidified fat; it does not interfere. Carefully rinse digestion flask with several portions  $\text{H}_2\text{O}$  and dil. to vol. with rinse  $\text{H}_2\text{O}$ .

Pipet 25 mL soln into original digestion flask and add ca 75 mL dilg soln, 25.111(b). Proceed as in 25.112, beginning "Adjust output of pump . . .", except aerate ca 1 min. 1  $\mu\text{g}$  std should give  $A \geq 0.400$ .

#### Alternative Digestion Method for Seafood (22)

(Do not change sample wt or acid vol. substantially; otherwise excessive pressure during heating may damage vessel.)

#### 25.115

#### Apparatus

*Digestion vessel*.—See Fig. 25:03. Stainless steel body supporting Teflon crucible and screw-on cap with Teflon liner to provide Teflon sealing surface. Teflon spout is snapped on outside rim to permit quant. transfer of contents without contact with metal parts. (Available from Uni-Seal Decomposition Vessels, PO Box 9463, Haifa, Israel.)

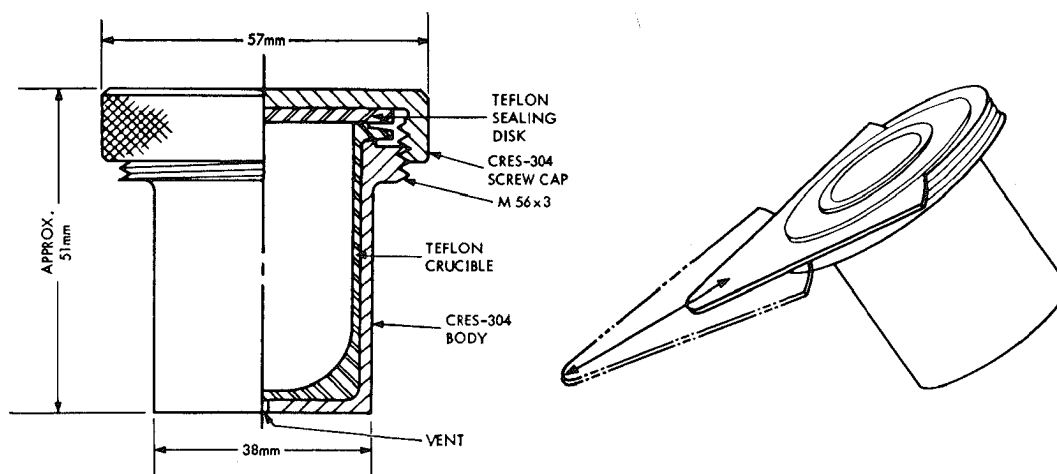

FIG. 25:03—Digestion vessel

## 25.116

**Digestion**

Accurately weigh  $1 \pm 0.1$  g sample (*Caution:* Do not use  $>300$  mg dry wt.) into digestion vessel, add 5.0 mL  $\text{HNO}_3$ , and close vessel by tightening screw cap. Place vessel, without tilting, into preheated  $150^\circ$  oven 30–60 min or until clear. Remove vessel and let cool to room temp. Unscrew cap, snap on spout, and transfer with aid of 95 mL dilg soln, 25.111(b), to 250 mL flask, 25.110(e). Proceed as in 25.112, beginning "Adjust output of pump . . ."

**Colorimetric Dithizone Method (23)—Official Final Action**

## 25.117

**Principle**

Sample is digested with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  under reflux in special app., Hg is isolated by dithizone extn, Cu is removed, and Hg is estd by photometric measurement of Hg dithizonate.

## 25.118

**Precautions**

Critical step is digestion of sample, which must be almost complete, otherwise residual org. matter may combine with Hg and prevent or hinder extn with dithizone. Oxidizing material in digest must also be destroyed or dithizone reagent is decomposed and Hg is not quant. extd. Because of volatility of Hg compds, careful heating of digest during sample prepn is required. Acidity of final sample soln (after partial neutzn with  $\text{NH}_4\text{OH}$ ) before extn should be ca 1*N* and not  $>1.2N$ . Do not use silicone grease in stopcocks.

## 25.119

**Apparatus**

(As Hg compds tend to adsorb on glassware, app. and particularly separators should be rinsed with dil.  $\text{HNO}_3$  and then with  $\text{H}_2\text{O}$ .)

**Special digestion apparatus.**—See Fig. 25:04. App. is made from Pyrex with  $\text{T}$  joints thruout. Unit A is modified Soxhlet extractor, 5 cm od, 200 mL capacity to overflow, without inner siphon tube but equipped with stopcock on tube leading to digestion flask, D. With stopcock open, app. is in reflux position; when closed, unit serves as trap for condensed  $\text{H}_2\text{O}$  and acids. Top of A is attached to Friedrichs condenser, 35 cm long. Bottom of A is attached thru center neck of 2 neck  $\text{T}$  24/40 r-b 500 mL flask, D. Necks are 3 cm apart to provide clearance. Second neck is used for attaching 75 mL dropping funnel, B.

## 25.120

**Reagents**

(a) *Mercury std solns.*—(1) *Stock soln.*—1 mg/mL. Prep. from dry, recrystd  $\text{HgCl}_2$  (67.7 mg/50 mL). (2) *Working soln.*—2  $\mu\text{g/mL}$  is convenient. Prep. from stock soln and store in Pyrex bottles. Add HCl in proportion of 8 mL/L to all stds before dilg to final vol.

(b) *Chloroform.*—See 25.022(b).

(c) *Dithizone soln.*—See 25.095(e). Reagent as now distributed needs no purification for this method. Prep. stock soln in redistd  $\text{CHCl}_3$  (100 mg/L is convenient) and store in refrigerator. Prep. dilns as needed.

(d) *Sodium thiosulfate soln.*—1.5%. Prep. daily.

(e) *Sodium hypochlorite soln.*—Preferably 5% available Cl reagent. As distributed, reagent varies in available Cl content. Det. strength by 6.112. Store in refrigerator when not in use and det. titer monthly. (Certain preps of hypochlorite intended for household use contain traces of Hg. If these preps are used, det. blank. Reagent with  $>0.1 \mu\text{g Hg/mL}$  should not be used.)

(f) *Dilute acetic acid.*—30% by vol.

(g) *Hydroxylamine hydrochloride soln.*—20% w/v. Ext with dil. dithizone until  $\text{CHCl}_3$  layer remains green, remove excess dithizone with  $\text{CHCl}_3$ , and filter.

## 25.121

**Preparation of Sample**

(Conduct acid digestion in hood.)

In all detns use wt sample equiv. to  $\leq 10$  g dry wt.

(a) *Fresh fruits or vegetables and beverages.*—Place weighed sample in digestion flask with 6 glass beads, connect assembly, and add, thru dropping funnel, 20 mL  $\text{HNO}_3$ . Pass rapid stream of  $\text{H}_2\text{O}$  thru condenser, adjust stopcock of Soxhlet unit to reflux position, and apply small flame to flask. Use asbestos board with 2–5 cm diam. hole between flask and flame. (Original reaction must not proceed violently or evolved  $\text{NO}_2$  will carry vapors of digest mech. thru condenser and cause loss of Hg.) After initial reaction is complete, apply heat so that digest just refluxes. If mixt. darkens, add  $\text{HNO}_3$  dropwise thru funnel as needed. Continue refluxing 0.5 hr, or until digest does not change consistency, and cool.

Slowly add 20 mL cold  $\text{HNO}_3$ - $\text{H}_2\text{SO}_4$  mixt. (1+1). (Use 10 mL acid mixt. for  $\leq 5$  g (dry wt) of sample.) Heat with small flame, subsequently adding  $\text{HNO}_3$  dropwise as needed to dispel darkening of digest. Continue heating until fibrous material (fruit skin, cellulose, etc.) is apparently digested. Turn stopcock of

Soxhlet unit to trap  $\text{H}_2\text{O}$  and acids, and continue heating. Let digest become dark brown (not black) before adding further increments of  $\text{HNO}_3$ . (Fats and waxes cannot be totally digested by the hot acids under reflux. Therefore no attempt should be made to effect complete digestion in this step.) When all except fat and wax is in soln, let digest cool, and cautiously drain  $\text{H}_2\text{O}$  and acids into main digest. Cool, and pour two 25 mL portions  $\text{H}_2\text{O}$  thru condenser and intermediate unit. Remove reaction flask, chill under cold  $\text{H}_2\text{O}$  or by surrounding with ice to solidify fats and waxes, and filter off insol. matter on small pledget of glass wool. Rinse reaction flask and filter pad successively with two 10 mL portions  $\text{H}_2\text{O}$ . Remove Soxhlet unit, and wash it and

flask with hot  $\text{H}_2\text{O}$  to remove insol. material. Pour hot  $\text{H}_2\text{O}$  thru condenser to remove volatile fats and oils. Discard all washings.

Connect flask contg filtered sample soln to assembled app., heat, and collect  $\text{H}_2\text{O}$  and acids in trap. Complete digestion, using small addns of  $\text{HNO}_3$  as needed. In final stage of digestion, adjust flame until digest reaches incipient boiling (soln simmers) and acid vapors do not rise beyond lower half of condenser. Continue heating 15 min after last addn of  $\text{HNO}_3$ . Digest should now be colorless or pale yellow. Let digest cool, drain trapped liqs carefully into reaction flask, and add two 50 mL portions  $\text{H}_2\text{O}$  thru condenser. Reflux soln until all  $\text{NO}_2$  is expelled from app. Add 5 mL 40% w/v urea soln and reflux 15 min. (Digest should be colorless or pale yellow.)

(b) *Dried fruit, cereal, seeds, and grains.*—Dil. sample with 50 mL  $\text{H}_2\text{O}$  before adding  $\text{HNO}_3$ , and proceed with sample prepn as in (a).

(c) *Meats, fish, and biological material.*—Because of high fat and protein content of these materials, conduct initial digestion carefully to avoid foaming of digest into condenser. Add 20 mL  $\text{HNO}_3$  to sample, swirl flask, and let stand 0.5 hr in digestion assembly before heating. Add 25 mL  $\text{H}_2\text{O}$  and heat cautiously with small rotating flame until initial vigorous reaction is over and foaming ceases. Proceed as in (a).

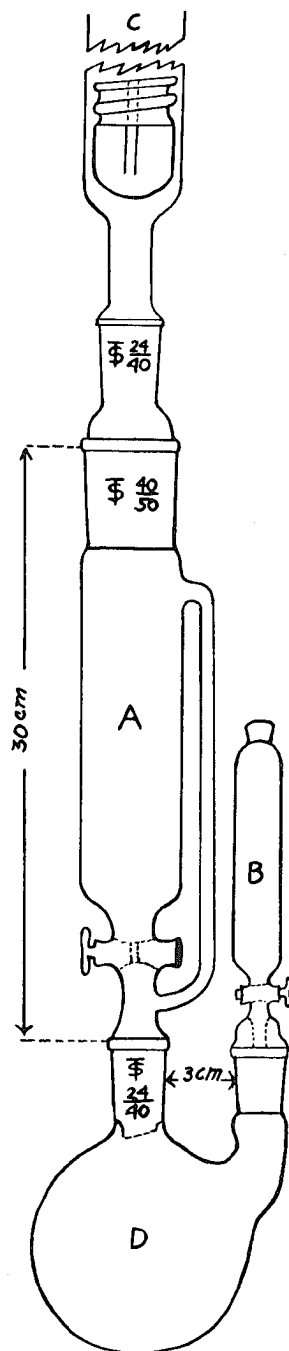

FIG. 25:04—Special digestion apparatus for mercury residues

## 25.122

### Isolation of Mercury

Titrate 1 mL prep'd sample soln, 25.121, with std alkali. Add calcd amt of conc'd  $\text{NH}_4\text{OH}$  to reduce acidity to 1.0N: swirl flask during addn of the  $\text{NH}_4\text{OH}$  to avoid local excess. (Soln should never be ammoniacal to avoid formation of Hg complexes.)

Transfer sample soln to 500 mL separator. Add 10 mL 4 mg/L dithizone and shake vigorously 1 min. (If characteristic green of dithizone is visible in  $\text{CHCl}_3$  layer, indicating excess of dithizone, amt of Hg is within 0–5  $\mu\text{g}$ .) Let layers sep., and drain  $\text{CHCl}_3$  layer quickly to second separator contg 25 mL 0.1N  $\text{HCl}$  and 5 mL  $\text{H}_2\text{NOH.HCl}$  soln. (Small amt of oxidizing material may still be present. On long contact with dithizone soln, oxidizing substances may destroy dithizone reagent and prevent extn of Hg.)

Repeat extn of sample soln with two 5 mL portions dithizone soln, transferring  $\text{CHCl}_3$  layer successively to second separator. If first extn indicates  $>5 \mu\text{g}$  Hg, add stronger concns of dithizone, as indicated by table, 25.124, until, after 1 min vigorous shaking,  $\text{CHCl}_3$  layer contains dithizone in marked excess. Drain  $\text{CHCl}_3$  layer into second separator contg 0.1N  $\text{HCl}$  and again ext sample soln with two 10 mL portions 4 mg/L dithizone soln, draining each successive ext into second separator.

Shake contents of second separator vigorously 1 min, and drain  $\text{CHCl}_3$  layer into third separator contg 50 mL 0.1N  $\text{HCl}$ . (Shaking dithizone ext with dil. acid in second separator removes entrained org. matter. With biological materials or those of high protein content, aq. layer is usually light yellow because of nitrated org. compds. Small amts are carried into third separator where they are destroyed by  $\text{Cl}_2$ .) Ext soln in second separator with 1–2 mL  $\text{CHCl}_3$  and transfer org. layer to third separator.

To contents of third separator add 2 mL  $\text{Na}_2\text{S}_2\text{O}_3$  soln, shake vigorously 1 min, let layers sep., drain off  $\text{CHCl}_3$  as completely as possible, and discard. (Cu if present is removed as dithizonate.) Ext again with 1–2 mL  $\text{CHCl}_3$ , drain carefully, and discard. Add 3.5 mL  $\text{NaOCl}$  reagent (or enough soln of different titer to furnish 175 mg available  $\text{Cl}_2$ ) to decompose Hg thiosulfate complex and to oxidize excess thiosulfate, and shake vigorously 1 min. Add 5 mL  $\text{H}_2\text{NOH.HCl}$  reagent from pipet, taking care to wet both stopper and neck of separator. Shake vigorously 1 min. Hold mouth of separator in front of air vent and blow out any remaining gaseous  $\text{Cl}_2$ . Stopper separator and shake vigorously

1 min. (It is imperative that all hypochlorite be reduced. Trace amts remaining would oxidize dithizone, subsequently added, to yellow oxidized form which would be measured in photometer as Hg.) Ext soln with 2–3 mL  $\text{CHCl}_3$ , drain off org. layer carefully, and discard. Final aq. soln should now be colorless.

**25.123****Determination**

To third separator add 3 mL 30% HOAc and appropriate vol. and concn of dithizone soln as indicated by table, **25.124**, and proceed with colorimetric detn of Hg as in **25.124**, converting *A*, measured at 490 nm, to  $\mu\text{g}$  Hg from working curve.

**25.124****Preparation of Standard Curve**

Following table is useful in prepg std curve and for establishing approx. Hg range in sample soln when 1 cm cells are used:

Hg Range, $\mu\text{g}$	Dithizone Concn, mg/L	Volume Dithizone, mL
0–10	6	5
0–50	10	25
0–100	10	40

Prep. working curve of required range, starting with blank and extending to final std of range, with 4 intermediate increments. Add appropriate amts of Hg to 50 mL 0.1*N* HCl in separator. Add 5 mL  $\text{H}_2\text{NOH.HCl}$  reagent and 5 mL  $\text{CHCl}_3$ , and shake vigorously 1 min. Let layers sep., drain off  $\text{CHCl}_3$ , and discard, being careful to remove as completely as possible all droplets of  $\text{CHCl}_3$ . Add 3 mL 30% HOAc and appropriate vol. dithizone soln, shake vigorously 1 min, and let layers sep. (HOAc aids in stabilizing mercuric dithizonate.) Insert cotton pledget into stem of separator and collect dithizone ext (discarding first mL) in test tube for transfer to appropriate cell. Make photometer readings at 490 nm. (Since both dil. dithizone and mercuric dithizonate are somewhat unstable, read immediately.) Plot *A* against  $\mu\text{g}$  Hg.

**NICKEL****25.125 Atomic Absorption Method for Tea  
Official Final Action**

See **25.044–25.048**.

**SELENIUM****Fluorometric Method (24)—Official Final Action****25.126****Apparatus**

(a) *Fluorometer*.—Filter fluorometer or spectrophotofluorometer capable of excitation at 366 nm and detection of fluorescence at 525 nm. (*Caution*: See **51.008**.)

(b) *Cuvets or tubes*.—Pyrex culture tubes, 12 × 75 mm, selected by matching, are suitable for fluorometer.

(c) *Wrist-action shaker*.—Model BB (Burrell Corp.), or equiv., set at max. speed.

(d) *Separators*.—Glass, 250 and 125 mL, with Teflon stop-cocks.

**25.127****Reagents**

(Use anal. grade reagents and glass-distd  $\text{H}_2\text{O}$  thruout except as noted.)

(a) *Nitric acid*.—Distil from glass, discarding first and final 10%.

(b) *Dilute sulfuric acid*.—5*N*. Dil. 140 mL  $\text{H}_2\text{SO}_4$  to 1 L with  $\text{H}_2\text{O}$ .

(c) *Ammonium hydroxide soln*.—Approx. 6*N*. Dil. 400 mL  $\text{NH}_4\text{OH}$  to 1 L with  $\text{H}_2\text{O}$ .

(d) *Disodium EDTA soln*.—0.02*M*. Dissolve 7.445 g  $\text{Na}_2\text{H}_2\text{EDTA} \cdot 2\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ .

(e) *2,3-Diaminonaphthalene (DAN) soln*.—1 mg/mL. Pulverize DAN (purest grade available; product from Aldrich Chemical Co. has been found satisfactory) in clean mortar to fine powder. Insert glass wool plug in stem of 250 mL separator and add 150 mL 5*N*  $\text{H}_2\text{SO}_4$ . Transfer 0.150 g DAN to separator and place on shaker 15 min to dissolve. Add 50 mL cyclohexane and shake 5 min. Let phases sep. 5 min, drain lower phase into another separator, and discard cyclohexane (upper) phase. Repeat cyclohexane extn twice more; after third extn, drain lower phase into low-actinic g-s flask, add 1 cm layer hexane, and store in cold. Soln is stable several weeks.

(f) *Selenium std soln*.—(1) *Stock soln*.—100  $\mu\text{g}$ /mL. Dissolve 0.1000 g black Se (purity  $\geq 99.9\%$ ) in ca 5 mL  $\text{HNO}_3$ , (a), and warm to dissolve. Dil. with  $\text{H}_2\text{O}$  and 20 mL 5*N*  $\text{H}_2\text{SO}_4$  to 1 L. (2) *Working soln*.—Dil. stock soln with  $\text{H}_2\text{O}$  and 5*N*  $\text{H}_2\text{SO}_4$  to give Se concns in 0.1*N*  $\text{H}_2\text{SO}_4$  appropriate for level of Se expected in sample. Store all solns in all-glass containers. Solns are stable indefinitely.

**25.128****Preparation of Standard Curve  
and Fluorometric Blank**

Conduct appropriate vols of Se std solns ( $\leq 10$  mL contg  $\leq 800$  ng Se) and 10 mL  $\text{H}_2\text{O}$  each thru entire detn, including digestion, along with samples. Zero fluorometer against blank soln and read fluorescence at 525 nm or subtract blank fluorescence from that of stds. Plot reading against ng Se/6 mL cyclohexane soln. Prepare new std curve daily.

**25.129****Determination**

(To ensure adequate cleanliness for fluorometry, acid-wash all glassware except cells. In particular, clean Kjeldahl flasks and erlenmeyers, separators, centr. tubes, and glass beads before each detn. Rinse glassware with hot  $\text{H}_2\text{O}$ , dry in oven, and wash with hot  $\text{HNO}_3$ - $\text{H}_2\text{SO}_4$  (1+1). Rinse with hot tap  $\text{H}_2\text{O}$  followed by distd  $\text{H}_2\text{O}$  and dry in oven or let air dry. Rinse cells with alcohol followed by acetone. Do not use plastic ware other than that mentioned. *Caution*: See **51.019**, **51.026**, **51.028**, and **51.030**.)

Place accurately weighed sample contg  $\leq 1.0$  g dry matter and  $\leq 0.8$   $\mu\text{g}$  Se with 3 glass beads into 100 mL Kjeldahl flask contg 10 mL  $\text{H}_2\text{O}$ , and swirl to wet sample. Add 10 mL  $\text{HNO}_3$ , (a). (Alternatively, omit the 10 mL  $\text{H}_2\text{O}$ , add 10 mL  $\text{HNO}_3$ , or more if all  $\text{HNO}_3$  is absorbed by sample, and let digest overnight at room temp.) Heat cautiously to reduce vol. to ca 5 mL, taking care to prevent severe foaming or bumping, and cool. Add 6.0 mL 70%  $\text{HClO}_4$  and 5.0 mL  $\text{H}_2\text{SO}_4$ , return to cool heater, and heat until soln first turns yellow and then becomes colorless. Avoid charring of sample during digestion which may result in loss of Se. If charring occurs, repeat analysis with new sample, using higher  $\text{HNO}_3$ - $\text{HClO}_4$ /sample wt ratio. If this fails, add small amts of  $\text{HNO}_3$  at first signs of darkening.

Remove flask from heat, swirl to wet entire bulb area and lower neck of flask, replace flask on heater, and continue heating until soln becomes colorless and white fumes appear.

Remove flask from heat, swirl, add 1.0 mL 30%  $\text{H}_2\text{O}_2$ , rinsing walls of flask, and swirl until fuming ceases. Resume heating until contents boil briskly and white fumes are again evolved. Repeat addn of  $\text{H}_2\text{O}_2$  and heating twice more, and continue final heating 5 min after appearance of white fumes. Let flask cool, add 30 mL  $\text{H}_2\text{O}$ , rinsing walls of flask, and mix thoroly. Transfer quant. to 250 mL g-s erlenmeyer, using two 10 mL and one 5 mL  $\text{H}_2\text{O}$  rinses. Add, successively with mixing, 10.0 mL EDTA soln, 25.0 mL 6*N*  $\text{NH}_4\text{OH}$ , and 5.0 mL DAN soln. Bring quickly to brisk boil and boil exactly 2 min.

Let reaction mixt. stand at room temp. for definite interval

between 1 and 2 hr. Use *same* interval for all samples, stds, and blank in set. Accurately add 6.0 mL cyclohexane, stopper flask, and place on shaker 5 min. Transfer to 125 mL separator, and let phases sep. ca 5 min. Discard lower aq. phase and drain cyclohexane soln into 15 mL centr. tube. Centrf. 5 min to further sep. H<sub>2</sub>O and transfer ca 5 mL to fluorometer cell.

Zero fluorometer against reagent blank and read fluorescence of sample at 525 nm. Alternatively, subtract fluorescence of blank from that of sample. Det. Se content from std curve. Altho fluorescence readings for both samples and blanks increase with time, net readings (sample – blank) remain constant with 1–2 hr complexing period.

#### 25.130 ★ Titrimetric Method (25)—Official Final Action ★

Sample is digested with HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> in presence of HgO fixative. Se is sepd by distn as volatile bromide, reduced to elementary Se with SO<sub>2</sub>, isolated, and estd as H<sub>2</sub>SeO<sub>3</sub> by titrn with std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> and I. See 25.121–25.126, 12th ed.

#### TIN—OFFICIAL FINAL ACTION

#### 25.131 Preparation of Sample

Digest 50–100 g sample as in 25.008.

#### ★ Gravimetric Method (26) ★

#### 25.132

#### Reagents

(a) *Wash soln.*—Mix 100 mL satd NH<sub>4</sub>OAc soln with 50 mL HOAc and 850 mL H<sub>2</sub>O.

(b) *Ammonium polysulfide soln.*—(Caution: See 51.059.) Pass H<sub>2</sub>S into 200 mL NH<sub>4</sub>OH in bottle immersed in running H<sub>2</sub>O or in ice-H<sub>2</sub>O until gas is no longer absorbed; add 200 mL NH<sub>4</sub>OH and dil. with H<sub>2</sub>O to 1 L. Digest this soln with 25 g flowers of S several hr and filter.

#### 25.133

#### Determination

(Caution: See 51.059.)

Add 200 mL H<sub>2</sub>O to digested sample and transfer to 600 mL beaker. Rinse Kjeldahl flask with 3 portions boiling H<sub>2</sub>O, making total ca 400 mL. Cool, and add NH<sub>4</sub>OH until just alk.; then add 5 mL HCl or 5 mL H<sub>2</sub>SO<sub>4</sub> (1+3) for each 100 mL soln. Place beaker, covered, on hot plate; heat to ca 95° and pass in slow stream of H<sub>2</sub>S 1 hr. Digest 1 hr at 95° and let stand 30 min longer.

Filter, and wash ppt of SnS alternately with 3 portions each of wash soln and hot H<sub>2</sub>O. Transfer filter and ppt to 50 mL beaker, add 10–20 mL (NH<sub>4</sub>)<sub>2</sub>S<sub>x</sub> soln, heat to bp, and filter. Treat contents of beaker with 2 addnl portions hot (NH<sub>4</sub>)<sub>2</sub>S<sub>x</sub> soln and wash filter with hot H<sub>2</sub>O. Acidify combined filtrate and washings with HOAc (1+9), digest on hot plate 1 hr, let stand overnight, and filter thru double 11 cm paper. Wash alternately with 2 portions each of wash soln and hot H<sub>2</sub>O and dry thoroly in weighed porcelain crucible. Ignite over Bunsen flame, very gently at first to burn off paper and to convert sulfide to oxide; then partly cover crucible and heat strongly over large Bunsen or Meker burner. (SnS must be roasted gently to SnO<sub>2</sub>, which then may be heated to high temp. without loss by volatilization.) Weigh as SnO<sub>2</sub> and calc. to metallic Sn, using factor 0.7877.

#### ★ Volumetric Method (27) ★

#### 25.134

#### Reagents

(a) *Air-free wash soln.*—Dissolve 20 g NaHCO<sub>3</sub> in 2 L boiled H<sub>2</sub>O and add 40 mL HCL. Prep. fresh.

★ Surplus method—see inside front cover.

(b) *Iodine std soln.*—0.01N. Stdze soln frequently against (c), adding asbestos mat and proceeding as in 25.135, omitting pptn with H<sub>2</sub>S and boiling with HCl and KClO<sub>3</sub>. Amt of Sn in soln used for stdzn should equal ca that contained in sample under examination.

(c) *Tin std soln.*—1 mg/mL. Dissolve 1 g Sn in ca 500 mL HCl and dil. to 1 L with H<sub>2</sub>O.

(d) *Sheet aluminum.*—About 30 gage, Sn-free.

(e) *Starch indicator.*—Dil. 1 g sol. starch to 200 mL.

#### 25.135

#### Determination

(Caution: See 51.047 and 51.086.)

Proceed as in 25.133 thru "Digest 1 hr at 95° and let stand 30 min longer."

Filter thru asbestos in Caldwell crucible, using suction. Wash ppt of SnS few times with H<sub>2</sub>O and transfer detachable bottom and asbestos pad to 300 mL erlenmeyer. Remove all traces of ppt from inside of crucible, using jet of hot H<sub>2</sub>O and policeman, and using min. amt of H<sub>2</sub>O for washing.

Add 100 mL HCl and 0.5 g KClO<sub>3</sub> to flask. Boil ca 15 min, making ca 4 more addns of smaller amts of KClO<sub>3</sub> as Cl is boiled out of soln. Wash particles of KClO<sub>3</sub> down from neck of flask with H<sub>2</sub>O and finally boil to remove Cl. Add ca 1 g sheet Al to dispel last traces of Cl.

Fit 2-hole rubber stopper to flask. Thru 1 hole pass bulbed glass tube that reaches nearly to surface of liq. Attach this tube to large CO<sub>2</sub> generator thru scrubber contg H<sub>2</sub>O. The CO<sub>2</sub> passes out of flask thru short, bulbed tube inserted in second hole of stopper and ending slightly below it. With rubber tube connect this second glass tube to another glass tube, ca 25 cm long, immersed in cylinder of H<sub>2</sub>O to depth of ca 20 cm. (This connection acts as seal to restrain any strong flow of gas when not desired and to permit pressure in flask.)

Raise delivery tube nearly out of H<sub>2</sub>O seal, allowing rapid flow of CO<sub>2</sub> for few min to dispel air from system. Then lower delivery tube into H<sub>2</sub>O seal, slightly raise stopper, and quickly drop into flask 1–2 g sheet Al, folded into narrow bent strip to prevent breaking flask. After Al dissolves completely, raise tube in H<sub>2</sub>O seal, letting CO<sub>2</sub> pass thru rapidly; place flask on hot plate and boil few min. Remove flask from heat and cool with tap or ice-H<sub>2</sub>O, continuing flow of CO<sub>2</sub>. Lower delivery tube into cylinder, disconnect flask, and, with glass plug, close rubber tube thru which CO<sub>2</sub> enters flask. Wash glass tubes, rubber stopper, and sides of flask with air-free wash soln, (a), add starch indicator, (e), and titr. immediately with 0.01N I.

If desired, make titrn by slightly raising rubber stopper after cooling and adding excess 0.01N I. Then disconnect flask; wash tubes, rubber stopper, and sides of flask with air-free wash soln; and titr. excess I with 0.01N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

#### Atomic Absorption Method (28)

#### Interim Official First Action

#### 25.136

#### Reagents and Apparatus

(a) *Atomic absorption spectrophotometer.*—With N<sub>2</sub>O-C<sub>2</sub>H<sub>2</sub> burner head, and reading device capable of 10× scale expansion. Sn hollow cathode and electrodeless discharge lamps are both suitable.

(b) *Digestion apparatus.*—Macro Kjeldahl; with 800 mL flasks carefully checked to be free of minute stress cracks.

(c) *Tin std soln.*—1000 µg/mL. Dissolve 1.000 g pure Sn in 150 mL HCl. Dil. to 1 L with H<sub>2</sub>O.

#### 25.137

#### Preparation of Sample

Weigh 20 g sample into 800 mL Kjeldahl flask. Wash down

inside neck of flask with small amt  $\text{H}_2\text{O}$ , add 3–4 boiling chips or glass beads, 60 mL  $\text{HNO}_3$ , and 20 mL  $\text{H}_2\text{SO}_4$ . Bring to bp at medium heat and continue boiling to dense white fumes. If soln turns dark, add 10 mL  $\text{HNO}_3$  and reheat to white fumes. Repeat as necessary until soln is clear and colorless or straw colored. Turn off heat. Let sample cool partially; then add ca 60 mL  $\text{H}_2\text{O}$  rapidly enough to cause boiling, but not so rapidly that soln is lost by spurting. Boil off  $\text{H}_2\text{O}$  until dense white fumes reappear. Remove from heat, let cool partially, and repeat  $\text{H}_2\text{O}$  addn and boiling to fumes. Turn off heat and let cool. Transfer quant. to 100 mL vol. flask with two 10 mL portions  $\text{H}_2\text{O}$ . Add 5 mL *satd*  $\text{NH}_4\text{Cl}$  soln, let sample cool completely, and carefully add 50 mL MeOH. (Caution: Do not let soln become too hot during MeOH addn. Cool under  $\text{H}_2\text{O}$  if necessary.) After soln has cooled to room temp., dil. to vol with  $\text{H}_2\text{O}$ . Small amt of finely divided cryst. ppt, usually  $\text{CaSO}_4$ , does not interfere. Conduct 1–2 reagent blanks with each series. For each sample and blank, add 1.00 mL  $\text{H}_2\text{O}$  to 25 mL vol. flask; to second 25 mL vol. flask add 1.00 mL std Sn soln, (c). Dil. both to vol. with sample soln (or blank soln).

**25.138****Determination**

Set up AA spectrophtr according to manufacturer's specifications for org. solvs. Use 235.5 nm Sn line and  $\text{N}_2\text{O}-\text{C}_2\text{H}_2$  flame. Optimize for max. Sn absorption. Depending on signal to noise ratio, scale expansion up to 10 $\times$  may be used. Set nonabsorbing conditions with  $\text{H}_2\text{O}$ . Read blanks, samples, and spiked soln in turn, aspirating  $\text{H}_2\text{O}$  between readings. Record *A* for all solns. Calculate:

$$X = (A' - A)/C, \text{ and} \\ \text{ppm Sn} = [25 \times F \times (A - A_0)]/24 X,$$

where: *A*, *A'*, and *A*<sub>0</sub> refer to sample, spiked sample, and blank, resp.; *C* = spiking soln concn (40 ppm); and *F* = sample diln. factor (5).

**TITANIUM (29)—OFFICIAL FINAL ACTION**

(Applicable to cheese. Caution: See 51.030.)

**25.139****Standard Solution**

*Titanium dioxide std soln.*—0.1 mg/mL. Accurately weigh 50 mg  $\text{TiO}_2$  and transfer to 250 mL beaker; add 15 g anhyd.  $\text{Na}_2\text{SO}_4$  and 50 mL  $\text{H}_2\text{SO}_4$ . Add boiling chips, cover with watch glass, and heat to bp on hot plate to dissolve. Cool, and cautiously add 100 mL  $\text{H}_2\text{O}$  with stirring. (Warm on steam bath if soln becomes cloudy.) Cool, transfer soln to 500 mL vol. flask contg 200 mL  $\text{H}_2\text{O}$ , and dil. to vol. with  $\text{H}_2\text{O}$ .

**25.140****Preparation of Sample**

Weigh, to nearest 0.1 g, 10 g prepd sample, 16.232, into 100 mL Pt dish and char under IR lamp. Place in cold furnace and ignite at 850° to white ash.

Cool, add ca 1.5 g anhyd.  $\text{Na}_2\text{SO}_4$  and 10 mL  $\text{H}_2\text{SO}_4$ , cover with watch glass, and bring to bp on hot plate to dissolve. Turn heat off and let cool on hot plate. Cautiously rinse cover, carefully add ca 30 mL  $\text{H}_2\text{O}$ , and mix with stirring rod to disperse any insol. salts. Heat on steam bath if insol. material forms cake on bottom of dish.

Transfer quant. to 100 mL vol. flask with aid of ca 40 mL  $\text{H}_2\text{O}$ . If soln is cloudy, heat on steam bath or in boiling  $\text{H}_2\text{O}$  bath to clarify. Cool, and dil. to vol. with  $\text{H}_2\text{O}$ .

**25.141****Preparation of Standard Curve**

Transfer 0, 1, 2, 3, 4, and 5 mL  $\text{TiO}_2$  std soln to sep. 5 mL g-s graduates (or vol. flasks) and dil. to vol. with  $\text{H}_2\text{SO}_4$  (1+9). Add

0.2 mL 30%  $\text{H}_2\text{O}_2$ , mix, and det. *A* on recording spectrophtr in 1.0 cm cells from 650 to 325 nm against 0.2 mL 30%  $\text{H}_2\text{O}_2$  in 5.0 mL  $\text{H}_2\text{SO}_4$  (1+9). Det. *A* at max., ca 408 nm, and prep. std curve.

**25.142****Determination**

Transfer 3.0 mL sample soln to 5 mL g-s graduate (or vol. flask), dil. to vol. with  $\text{H}_2\text{SO}_4$  (1+9), and continue as in 25.141, beginning "Add 0.2 mL 30%  $\text{H}_2\text{O}_2$ , . . ."

Det. mg  $\text{TiO}_2$  in sample from std curve, and calc. as %  $\text{TiO}_2$ .

**ZINC—OFFICIAL FINAL ACTION****Colorimetric Method (30)****25.143****Principle**

Method involves wet oxidn of sample; elimination of Pb, Cu, Cd, Bi, Sb, Sn, Hg, and Ag as sulfides with added Cu as scavenger agent; simultaneous elimination of Co and Ni by extg metal complexes of  $\alpha$ -nitroso- $\beta$ -naphthol and dimethylglyoxime, resp., with  $\text{CHCl}_3$ ; extn of Zn dithizonate with  $\text{CCl}_4$ ; transfer of Zn to dil. HCl; and final extn of Zn dithizonate for color measurement.

**25.144****Reagents**

(All  $\text{H}_2\text{O}$  must be redistd from glass. Pyrex glassware should be used exclusively and must be scrupulously cleaned with hot  $\text{HNO}_3$ . Purify  $\text{HNO}_3$  (usually unnecessary) and  $\text{NH}_4\text{OH}$  by distn in Pyrex if appreciably contaminated. Test  $\text{H}_2\text{SO}_4$  if Zn contamination is suspected.)

(a) *Copper sulfate soln.*—2 mg Cu/mL. Dissolve 8 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(b) *Ammonium citrate soln.*—Dissolve 225 g  $(\text{NH}_4)_2\text{HC}_6\text{H}_5\text{O}_7$  in  $\text{H}_2\text{O}$ , make alk. to phenol red with  $\text{NH}_4\text{OH}$  (pH 7.4, first distinct color change), and add 75 mL in excess. Dil. to 2 L. Ext this soln immediately before use as follows: Add slight excess of dithizone and ext with  $\text{CCl}_4$  until solv. layer is clear bright green. Remove excess dithizone by repeated extn with  $\text{CHCl}_3$ , and finally ext once more with  $\text{CCl}_4$ . (It is essential that excess dithizone be entirely removed, otherwise Zn will be lost during elimination of Co and Ni.)

(c) *Dimethylglyoxime soln.*—Dissolve 2 g reagent in 10 mL  $\text{NH}_4\text{OH}$  and 200–300 mL  $\text{H}_2\text{O}$ , filter, and dil. to 1 L.

(d) *Alpha-nitroso-beta-naphthol soln.*—Dissolve 0.25 g in  $\text{CHCl}_3$  and dil. to 500 mL.

(e) *Chloroform.*—Redistd.

(f) *Diphenylthiocarbazone (dithizone) soln.*—Dissolve 0.05 g dithizone in 2 mL  $\text{NH}_4\text{OH}$  and 100 mL  $\text{H}_2\text{O}$ , and ext repeatedly with  $\text{CCl}_4$  until solv. layer is clear bright green. Discard solv. layer and filter aq. portion thru washed ashless paper. (This soln is best prepd as needed, since it is only moderately stable, even when kept in dark and under refrigeration.)

(g) *Carbon tetrachloride.*—Redistd.

(h) *Dilute hydrochloric acid.*—0.04*N*. Dil. required amt of HCl with  $\text{H}_2\text{O}$  (redistd acid may be used altho usually unnecessary).

(i) *Zinc std solns.*—(1) *Stock soln.*—500  $\mu\text{g/mL}$ . Dissolve 0.500 g pure granulated Zn in slight excess of dil. HCl and dil. to 1 L. (2) *Working soln.*—5  $\mu\text{g/mL}$ . Dil. 10 mL stock soln to 1 L with 0.04*N* HCl.

**25.145****Preparation of Sample**

(Caution: See 51.019, 51.026, 51.028, and 51.030.)

Weigh, into suitable size erlenmeyer, representative sample  $\leq 25$  g, estd to contain 25–100  $\mu\text{g}$  Zn. If sample is liq., evap. to small vol. Add  $\text{HNO}_3$  and heat cautiously until first vigorous

reaction subsides somewhat; then add 2–5 mL  $\text{H}_2\text{SO}_4$ . Continue heating, adding more  $\text{HNO}_3$  in small portions as needed to prevent charring, until fumes of  $\text{SO}_3$  evolve and soln remains clear and almost colorless. Add 0.5 mL  $\text{HClO}_4$  and continue heating until it is almost completely removed. Cool, and dil. to ca 40 mL. (Wet digestion and subsequent sulfide sepn may also be advantageously performed in small Kjeldahl flask.)

**25.146****Separation of Sulfide Group**

(Caution: See 51.047 and 51.059.)

To  $\text{H}_2\text{SO}_4$  soln add 2 drops Me red and 1 mL  $\text{CuSO}_4$  soln, and neutze with  $\text{NH}_4\text{OH}$ . Add enough  $\text{HCl}$  to make soln ca 0.15*N* with respect to this acid (ca 0.5 mL excess in 50 mL soln is satisfactory); pH of soln as measured with glass electrode is 1.9–2.1. Pass stream of  $\text{H}_2\text{S}$  into soln until pptn is complete. Filter thru fine paper (Whatman No. 42, or equiv., previously fitted to funnel and washed with  $\text{HCl}$  (1+6), then with redistd  $\text{H}_2\text{O}$ ). Receive filtrate in 250 mL beaker, and wash flask and filter with 3 or 4 small portions  $\text{H}_2\text{O}$ . Gently boil filtrate until odor of  $\text{H}_2\text{S}$  can no longer be detected; then add 5 mL satd  $\text{Br-H}_2\text{O}$  and continue boiling until  $\text{Br}$ -free. Cool, neutze to phenol red with  $\text{NH}_4\text{OH}$ , and make slightly acid with  $\text{HCl}$  (excess of 0.2 mL 1+1  $\text{HCl}$ ). Dil. resultant soln to definite vol. For optimum conditions of measurement, soln should contain 0.2–1.0  $\mu\text{g}$  Zn/mL.

**25.147****Elimination of Nickel and Cobalt**

Transfer 20 mL aliquot of prepd soln to 125 mL separator; add 5 mL  $\text{NH}_4$  citrate soln, 2 mL dimethylglyoxime soln, and 10 mL  $\alpha$ -nitroso- $\beta$ -naphthol soln; and shake 2 min. Discard solv. layer and ext with 10 mL  $\text{CHCl}_3$  to remove residual  $\alpha$ -nitroso- $\beta$ -naphthol. Discard solv. layer.

**25.148****Isolation and Estimation of Zinc**

To aq. phase following removal of Ni and Co, which at this point has pH of 8.0–8.2, add 2.0 mL dithizone soln and 10 mL  $\text{CCl}_4$ , and shake 2 min. Let phases sep. and remove aq. layer as completely as possible, withdrawing liq. with pipet attached to vac. line. Wash down sides of separator with ca 25 mL  $\text{H}_2\text{O}$  and without shaking again draw off aq. layer. Add 25 mL 0.04*N*  $\text{HCl}$  and shake 1 min to transfer Zn to acid-aq. layer. Drain and discard solv., being careful to dislodge and remove drop that usually floats on surface. To acid soln add 5.0 mL  $\text{NH}_4$  citrate soln and 10.0 mL  $\text{CCl}_4$  (pH of soln at this point is 8.8–9.0).

Det. vol. dithizone to be added as follows: To separator contg 4.0 mL working Zn std (20  $\mu\text{g}$ ), dild to 25 mL with 0.04*N*  $\text{HCl}$ , 5.0 mL citrate buffer, and 10.0 mL  $\text{CCl}_4$ , add dithizone reagent in 0.1 mL increments, shaking briefly after each addn until faint yellow in aq. phase indicates bare excess of reagent. Multiply vol. dithizone soln required by 1.5 and add this vol. (to nearest 0.05 mL) to all samples. Shake 2 min. Pipet exactly 5.0 mL solv. layer into clean, dry test tube, dil. with 10.0 mL  $\text{CCl}_4$ , mix, and det. *T* (or *A*) at 540 nm.

**25.149****Preparation of Standard Curves**

Prep. series of separators contg 0, 5, 10, 15, and 20  $\mu\text{g}$  Zn dild to 25 mL with 0.04*N*  $\text{HCl}$ ; add 5.0 mL citrate buffer, and proceed as with final extn of Zn, 25.148.

Plot *T* in logarithmic scale (or *A* on linear scale) against concn and draw smooth curve thru points. (Intercept of this curve may vary slightly from day to day, depending on actual concn of dithizone used in final extn, but slope should remain essentially same.)

**Atomic Absorption Method (31)—Official Final Action****25.150****Principle**

Representative sample is dry or wet ashed. Residue is taken up in acid and dild to optimum working range. *A* of this soln as detd by AA spectrophotometry at 213.8 nm is converted to Zn concn thru calibration curve.

**25.151****Reagents**

(Use Pyrex glassware exclusively; clean thoroly before use with hot  $\text{HNO}_3$ . If glass beads are used to prevent bumping, clean first with strong alkali followed by hot  $\text{HNO}_3$ . Since Pt used in laboratory may contain significant traces of metals, clean Pt dishes by  $\text{KHSO}_4$  fusion followed by 10%  $\text{HCl}$  leach.)

(a) *Zinc std solns.*—(1) *Stock soln.*—500  $\mu\text{g}$ /mL. Dissolve 0.500 g pure Zn metal in 5–10 mL  $\text{HCl}$ . Evap. almost to dryness and dil. to 1 L with  $\text{H}_2\text{O}$ . Soln is stable indefinitely. (2) *Working soln.*—Dil. aliquots of stock soln with  $\text{H}_2\text{SO}_4$  (1+49) or 0.1*N*  $\text{HCl}$  (depending on method of ashing) to obtain  $\geq 5$  solns within range of instrument. Prep. stds in 0–10  $\mu\text{g}$ /mL range daily. (Do not use <2 mL pipets or <25 mL vol. flasks.)

(b) *Acids.*—Reagent grade  $\text{HNO}_3$ ,  $\text{HCl}$ , and  $\text{H}_2\text{SO}_4$ . Test acids for freedom from Zn by AA measurement of appropriately dild sample. If contaminated, purify  $\text{HNO}_3$  and  $\text{HCl}$  by distn. Further test purity of reagents and efficiency of cleaning by conducting blank detns by appropriate ashing method.

**25.152****Preparation of Sample Solution**

Prep. representative sample by mixing, blending, or grinding.

(a) *Wet ashing.*—Accurately weigh, into 300 or 500 mL Kjeldahl flask, representative sample  $\leq 10$  g, estd to contain 25–100  $\mu\text{g}$  Zn. (If sample is liq., evap. to small vol.) Add ca 5 mL  $\text{HNO}_3$  and cautiously heat until first vigorous reaction subsides. Add 2.0 mL  $\text{H}_2\text{SO}_4$  and continue heating, maintaining oxidizing conditions by adding  $\text{HNO}_3$  in *small* increments (large amts may introduce Zn) until soln is colorless. Continue heating until dense fumes of  $\text{H}_2\text{SO}_4$  are evolved and all  $\text{HNO}_3$  has been removed. Cool, dil. with ca 20 mL  $\text{H}_2\text{O}$ , filter thru fast paper (pre-washed) into 100 mL vol. flask, and dil. to vol. with  $\text{H}_2\text{O}$ . Dil. further, if necessary, with  $\text{H}_2\text{SO}_4$  (1+49) to attain working range of spectrophtr.

(b) *Dry ashing.*—Accurately weigh, into clean Pt dish, representative sample estd to contain 25–100  $\mu\text{g}$  Zn. Char under IR lamp and ash at temp.  $\leq 525^\circ$  until C-free. (Raise temp. of furnace slowly to  $525^\circ$  to avoid ignition.) Dissolve ash under watch glass in min. vol.  $\text{HCl}$  (1+1). Add ca 20 mL  $\text{H}_2\text{O}$  and evap. to near dryness on steam bath. Add 20 mL 0.1*N*  $\text{HCl}$  and continue heating ca 5 min. Filter thru fast paper into 100 mL vol. flask. Wash dish and filter with several 5–10 mL portions of 0.1*N*  $\text{HCl}$ , cool, and dil. to vol. with 0.1*N*  $\text{HCl}$ . Dil. further, if necessary, with 0.1*N*  $\text{HCl}$  to attain working range of instrument.

**25.153****Determination**

Set instrument to previously established optimum conditions or according to manufacturer's instructions. Det. *A* of ashed soln or dildn, and  $\geq 5$  stds within optimum working range, taking  $\geq 2$  readings (before and after sample readings). Flush burner with  $\text{H}_2\text{O}$  and check 0 point between readings. Det. Zn content from std curve obtained by plotting *A* against  $\mu\text{g}$  Zn/mL:

$$\text{ppm Zn} = [(\mu\text{g Zn/mL from curve}) \times (\text{dildn factor, mL})] / \text{g sample.}$$

## 26. Natural Poisons

### MYCOTOXINS

Mycotoxins should be handled as very toxic substances. Perform manipulations under hood whenever possible, and take particular precautions, such as use of glove box, when toxins are in dry form because of electrostatic nature and resulting tendency to disperse in working areas. Swab accidental spills of toxin with 5% NaOCl bleach. Rinse all glassware exposed to aflatoxins with 1% NaOCl soln and then wash thoroly. See JAOAC 48, 681(1965) for more detail on decontamination.

(Caution: See 51.005, 51.011, 51.018, 51.039, 51.040, 51.046, 51.055, 51.056, 51.061, 51.066, and 51.073.)

In following mycotoxin methods, TLC is critical sepn and detn step. Batch-to-batch variation in particle size and site activity of adsorbents, and variations such as temp. and humidity to which plates are exposed during handling and spotting require adjustments of layer thickness and solv. polarity. Reactive vapors, e.g.,  $O_3$ ,  $SO_2$ , and HCl, can affect adsorbents as well as stability of adsorbed spots. Perform TLC only in laboratory free of volatile reagents. If necessary to protect adsorbent layer and developed spots, handle TLC plates in box with inert atm. or place clean glass plate over adsorbent layer while spotting (with only spotting area exposed) and after development and drying.

Always dry plates thoroly before exposure to UV light. UV light from sunlight or fluorescent lamps can catalyze changes in compds being examined when exposed on adsorbent surface, particularly in presence of solv. Avoid exposure to UV light of undeveloped spots (use incandescent light) and expose developed spots to UV light for min. time needed for visualization.

#### 26.001

#### General Apparatus

(a) *Apparatus for sample size reduction.*—Hobart Vertical Cutter/Mixer (VCM); Wiley mill, Std Model No. 3; hammer mill, e.g., Fitzpatrick, Micropulverizer; disk mill, e.g., Straub, Bauer; Waring Blender; food cutter, e.g., Hobart Model 84181-D; meat chopper; Polytron; or equivs. Effective device for prep sample is Dickens-Satterwhite mill (available from Federal-State Inspection Service, PO Box 3050, Albany, GA 31706).

(b) *Centrifuge.*—International Size 2, or equiv.

(c) *Centrifuge bottles.*—250 mL.

(d) *Chromatographic tubes.*—22 × 300 mm with Teflon stop-cock, reservoir type (250 mL) (for 50 g samples); and 45 × 600 mm (for 1 kg samples).

(e) *Densitometer.*—Schoeffel SD 3000 (Schoeffel Instrument Div., 24 Booker St, Westwood, NJ 07675); Aminco-Bowman Spectrophotofluorometer 4-8202 with TLC scanner 4-8247 (American Instrument Co.); Perkin-Elmer fluorospectrometer MPF-2A or successors with TLC accessory 018-0057 (Perkin-Elmer Corp.); Zeiss chromatogram spectrophotometer (Carl Zeiss, Oberkochen, West Germany or 444-5th Ave, New York, NY 10018); or equivs. Follow instructions of manufacturer. Following refs contain supplementary information: J. Am. Oil Chem. Soc. 43, 665(1966), 45, 694(1968); JAOAC 51, 602(1968), 52, 61(1969), 54, 870(1971).

(f) *Funnel.*—150 mm with fluted S&S 588, or equiv., paper to fit; or buchner, 32 cm diam., with Whatman No. 1 paper, or equiv., to fit.

(g) *Heating block.*—Al or brass, 254 mm thick × 254 mm wide. Drilled 190 mm deep on 762 mm centers to accommodate vials.

(h) *High-speed blender.*—Explosion-proof, with 1 L (qt) jar.

Drill 32 mm ( $\frac{1}{2}$ " ) hole ca 1 cm from center of lid to permit escape of vapors.

(i) *Hollow polyethylene stoppers.*—13 mm top diam., 7 mm bottom diam.

(j) *Rotary evaporator.*—With continuous feed.

(k) *Thin layer chromatographic apparatus.*—Glass plates, 20 × 20 cm (ca 8 × 8"); Desaga/Brinkmann applicator; mounting board; spotting template; micro-syringe, 10  $\mu$ L; desiccating storage cabinet, Fisher 8-645-6; storage rack, SGA Scientific Inc., C-4116-3; Thomas-Mitchell tank, Arthur H. Thomas Co. 2749-F05; longwave 15 watt UV lamp (use with UV-absorbing eye-glasses) or Chromato-Vue cabinet equipped with one or two 15 watt lamps (Ultra-Violet Products, Inc.); or equivs.

(l) *Tube shaking machine.*—Vortex, or equiv.

(m) *Vials.*—1, 2, and 4 dram, screw-cap (Kimble Products No. 60910-L, but foil-lined).

(n) *Microflex tube.*—1 mL, (Kontes K-749000) fitted with Microflex valve (Kontes K-749100).

(o) *Wrist-action shaker.*—Burrell, or equiv.

(p) *Stirrer.*—Motor,  $\frac{1}{30}$  hp, 1400–1600 rpm, with stainless steel shaft and propeller blade.

#### 26.002

#### General Reagents

(a) *Benzene-acetonitrile mixt.*—98+2; prep. from ACS solvs stored in glass.

(b) *Boiling chips.*—SiC (Carborundum Co.). Float off fines and extraneous matter with  $H_2O$ , wash with acetone, and dry.

(c) *Diatomaceous earth.*—Hyflo Super-Cel.

(d) *Silica gel for thin layer chromatography.*—Any silica gel that meets following test may be used (test each shipment). (Macherey-Nagel GHR (Macherey, Nagel & Co., PO Box 307, D-516 Duren, Germany, distributed by Brinkmann Instruments, Inc.), Applied Science Adsorbosils-1 or -5, and Mallinckrodt Silic AR 4G or 7G have been found satisfactory.) Prep. TLC plates, spot, develop, and observe as in 26.031(a) and (b).

Place on same origin spot, from solns of stds, 10 ng each of aflatoxins  $B_1$ ,  $M_1$ , and  $G_1$ , 2 ng each of aflatoxins  $B_2$  and  $G_2$ , 1  $\mu$ g sterigmatocystin, and 50 ng each of ochratoxins A and B. Repeat application of test spots to give  $\geq 3$  test spots evenly spaced across plate. Place origin spots of individual mycotoxins adjacent to spots of multiple mycotoxins. Develop plate and examine. Individual mycotoxins of interest must be sepd from each other and appear in the following  $R_f$  sequence: Aflatoxins  $M_1$ ,  $G_2$ ,  $G_1$ ,  $B_2$  and  $B_1$ , ochratoxins B and A, and sterigmatocystin. Time for solv. front to travel 12 cm must be  $\leq 1.5$  hr.

On second plate, place number of origin spots contg amt of each mycotoxin which is barely visible under UV illumination employed, plus adjacent spots contg twice these amts to serve as guide. Develop and observe. Store in dark in clean air for  $\geq 18$  hr. Observe again. Disappearance of one or both spots after storage is evidence of excessive fading, and silica gel fails tests.

Note special requirement for silica gel to be used in aflatoxin methods for proper background sepn.

(e) *Sodium sulfate.*—Anhyd. granular ACS grade.

(f) *Solvents.*—ACS grade in glass: Acetonitrile, acetone, alcohol, benzene,  $CHCl_3$ , hexane, HOAc, MeOH, and pet ether. Ether (anhyd.,  $\leq 0.01\%$  alcohol).

## AFLATOXINS

Aflatoxins are extremely potent carcinogens to many animals. Neither effects of aflatoxins on man nor possible routes of entry are presently known. Observe precautions given in introductory statement of this chapter.

**26.003 Sampling and Preparation of Sample (1)—Procedure**

(*Caution:* Grinding of dry samples may result in airborne dust. Even if no toxin is present, there is potential harm from inhalations of mold spores or from allergic response to inhaled dust. Use protective mask and/or dust collector. Prep. samples in area sepd from anal. laboratory.)

(a) *Preparation of lot sample.*—Mycotoxin contamination of particulate products, such as grains and nuts, is likely to occur in pockets of high concn which may not be randomly distributed. Perform sampling and sample prepn with this factor in mind. Because of possibility of pockets of contamination, include total laboratory sample in sample prepn. Aim at max. practical size reduction and thoroughness of mixing to achieve effective distribution of contaminated portions. One contaminated peanut (ca 0.5 g) can contain enough aflatoxins to result in significant level when mixed with 10,000 peanuts (ca 5 kg or 10 lb). To obtain  $\geq 1$  piece of contaminated nut in each 50 g portion, the single bad nut must be reduced to 100 pieces, and these 100 pieces must be uniformly blended thru entire mass. To achieve this degree of size reduction, nut must be ground to pass No. 20 sieve. Altho further size reduction may not be needed with flours, liqs, or pastes, thoro mixing is still needed before removal of anal. sample. Adsorption of aflatoxins on sediments in liq. commodities is possible.

Batch-type size reduction equipment, **26.001(a)**, like Hobart VCM, Waring Blendor, Polytron, and food cutter reduce particle size and mix in one operation. With other types of size reduction equipment and when product is received in finely ground state, mixing is needed. Free flowing dry materials can be mixed in double cone or twin shell blender such as Twin Shell Blender. (Available from Patterson-Kelley Co., Inc., 100 Burson St, East Stroudsburg, PA 18301.) Grains are most easily ground in disk mill such as Bauer or Staub; soft materials are best handled with meat chopper. Pastes and powders can be mixed in food cutter or with flat beater in planetary mixer, e.g., Hobart Model A-120.

Greatest homogeneity of nut meats is achieved by reducing to paste with disk mill, liquefying the paste with *n*-heptane and mixing, and further grinding slurry with Polytron. Practical homogeneity of hard, in-shell nuts is achieved by size reduction in hammer mill, followed by mixing in planetary mixer or by simultaneous size reduction and mixing in Hobart VCM. Nut meats can be handled in Hobart VCM in same manner as in-shell nuts, if mixed with equal wt of grinding aid such as coarse-ground oyster shells.

When handling large samples, coarse-grind and mix entire sample, remove ca  $1/20$ , and regrind this portion to finer size for drawing anal. sample.

(b) *Drawing of analytical sample.*—Draw with same precautions as apply to lot sample. Wherever practical, divide by riffing or similar random dividing procedure until subdivision is close to desired sample wt. Where such subdivision is not practical, composite number of small randomly taken portions. With liqs. suspend any particulate matter before drawing anal. sample.

**Preparation of Standards—Official Final Action****26.004****Apparatus**

(Rinse all containers which contact aflatoxin solns with dil. acid,  $H_2O$ , and acetone, and dry.)

See **26.001(k)**, and(l), and in addn:

a) *Spectrophotometer.*—Capable of measurements from 200 to 400 nm, with 1 cm quartz-face cells.

Calibrate as follows: Det. *A* of the 3 solns of  $K_2Cr_2O_7$  in  $H_2SO_4$  (0.25, 0.125, and 0.0625 *mM*), **26.005(b)**, at max. absorption near 350 nm, against 0.018*N*  $H_2SO_4$  as solv. blank. Calc. molar absorptivity ( $\epsilon$ ) at each concn:  $\epsilon = (A \times 1000)/\text{concn in } mM$ . If the 3 values vary by more than guaranteed accuracy of *A* scale, check either technic or instrument. Average the 3  $\epsilon$  values to obtain  $\epsilon$ . Det. correction factor (*CF*) for particular instrument and cells by substituting in equation:  $CF = 3160/\epsilon$ , where 3160 is value for  $\epsilon$  of  $K_2Cr_2O_7$  solns. If *CF* is  $<0.95$  or  $>1.05$ , check either technic or instrument to det. and eliminate cause. (Use same set of cells in calibration and detn of purity.)

(b) *Analytical microbalance.*—With sensitivity of 0.001 mg.

**26.005****Reagents**

See **26.002(a)**, (d), (f), and in addn:

(a) *Sulfuric acid.*—Approx. 0.018*N*; dissolve 1 mL  $H_2SO_4$  in 2 L  $H_2O$ .

(b) *Potassium dichromate std solns.*—(1) *Approx. 0.25 millimolar (mM).*—Accurately weigh ca 78 mg  $K_2Cr_2O_7$  (primary std) and dissolve in 1.0 L 0.018*N*  $H_2SO_4$ ; calc. molarity to 3 significant figs (MW  $K_2Cr_2O_7 = 294.2$ ). (2) *Approx. 0.125mM.*—Dil. 25 mL 0.25mM  $K_2Cr_2O_7$  to 50 mL with 0.018*N*  $H_2SO_4$  in vol. flask. (3) *Approx. 0.0625mM.*—Dil. 25 mL 0.125mM  $K_2Cr_2O_7$  to 50 mL with 0.018*N*  $H_2SO_4$  in vol. flask.

**Primary Standards (2)**

(Mycotoxin stds are available from: Calbiochem; Rijksinstituut voor de Volksgezondheid, PO Box 1, 3720 BA Bilthoven, The Netherlands; Makor Chemicals Ltd., Box 6570, Jerusalem, 91060 Israel; Applied Science Laboratories, Inc.; Senn Chemicals, Laboratorium Guido A. Senn, Postfach 2, CH-8157 Dielsdorf, Switzerland; Aldrich Chemical Co.; ICN K&K Laboratories, Inc.; Myco Lab Co., P.O. Box 321, Chesterfield MO 63017; RFR Corp., 1 Main St, Hope, RI 02831, C. Roth, Postfach 1387, 7500 Karlsruhe 1, FDR; Sigma Chemical Co., Supelco Inc; TCI Tridom Chemical Inc, Hauppauge, NY 11787.)

**26.006****Criteria of Purity**

Aflatoxins  $B_1$ ,  $B_2$ ,  $G_1$ , and  $G_2$  to be used as primary stds must meet following criteria of purity: (1) chromatgc purity as detd by **26.010**, (2) molar absorptivities within confidence limits given in Table **26:01**, (3) absorption peak ratios within confidence limits given in Table **26:02**.

**Table 26:01 Molar Absorptivities of Aflatoxins in Methanol and 95% Confidence Limits Expected from Single Determination of Molar Absorptivity**

Aflatoxin	$\lambda$ , nm	Molar Absorptivity in MeOH	95% Confidence Limits ( $\pm$ )
$B_1$	223	22,100	1,600
	265	12,400	800
	360	21,800	1,100
$B_2$	222	18,600	1,000
	265	12,100	600
	362	24,000	500
$G_1$	216	27,400	2,500
	242	9,600	300
	265	9,600	1,200
	362	17,700	700
$G_2$	214	25,300	2,300
	244	10,500	300
	265	9,000	1,100
	362	19,300	800

**Table 26:02 Ratios of Major Peaks of UV Absorption Spectra of Aflatoxins in Methanol and 95% Confidence Limits Expected from Single Spectra**

Major Peaks Compared, nm	Parameter	Aflatoxins			
		B <sub>1</sub>	B <sub>2</sub>	G <sub>1</sub>	G <sub>2</sub>

**26.007 Preparation of Solutions in Methanol and UV Measurements**

Weigh ca 1 mg aflatoxin std to nearest 0.001 mg and transfer quant. to 100 mL vol. flask. Dissolve in and dil. to vol. with MeOH. Calc. concn of soln in  $\mu\text{g/mL}$ . Measure *A* of soln at max. absorption, Table 26:01. Calc. molar absorptivities:

$$\epsilon = (A \times MW \times 1000) / (\mu\text{g aflatoxin/mL}),$$

where *MW* = molecular wt of aflatoxin (B<sub>1</sub>, 312; B<sub>2</sub>, 314; G<sub>1</sub>, 328; G<sub>2</sub>, 330).

Calc. ratios of *A* for each aflatoxin at wavelengths given in Table 26:02.

**Standards for Thin Layer Chromatography (2)****26.008 Preparation of Solutions**

(a) For aflatoxin stds received as dry films or crystals.—To container of dry aflatoxins B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, or G<sub>2</sub>, add vol. benzene-CH<sub>3</sub>CN, 26.002(a), calcd to give concn of 8–10  $\mu\text{g/mL}$ . For aflatoxin M<sub>1</sub>, use CH<sub>3</sub>CN. Use label statement of aflatoxin wt as guide. Vigorously agitate soln 1 min on Vortex shaker and transfer without rinsing to convenient size g-s flask. (Dry films on glass are not completely recoverable because of adsorption. Continued contact with solv. may result in slow dissoln.) Do not transfer dry aflatoxin for weighing or other purposes unless facilities are available to prevent dissemination of aflatoxins to surroundings due to electrostatic charge on particles.

(b) For aflatoxin stds received as solns.—Transfer soln to convenient size g-s flask. Dil., if necessary, to adjust concn to 8–10  $\mu\text{g/mL}$ .

**26.009 Determination of Aflatoxin Concentration**

Record UV spectrum of aflatoxin soln from 330 to 370 nm against benzene-CH<sub>3</sub>CN, 26.002(a), or CH<sub>3</sub>CN (for aflatoxin M<sub>1</sub>), in ref. cell. Det. concn of aflatoxin soln by measuring *A* at wavelength of max. absorption close to 350 nm and using following equation:

$$\mu\text{g aflatoxin/mL} = (A \times MW \times 1000 \times CF) / \epsilon,$$

where *CF* = correction factor obtained in 26.004(a) and *MW* and  $\epsilon$  are as follows:

Aflatoxin	MW	$\epsilon$
B <sub>1</sub>	312	19,800
B <sub>2</sub>	314	20,900
G <sub>1</sub>	328	17,100
G <sub>2</sub>	330	18,200
M <sub>1</sub>	328	19,850

Return aflatoxin soln to original g-s flask. (Normal exposure to UV light during *A* measurement results in no observable conversion to photoproducts.)

**26.010 Determination of Chromatographic Purity**

Follow TLC technic described in 26.031(a) and (b). Spot successively, at 2 cm intervals, 5  $\mu\text{L}$  resolution ref. std, 26.012, 5  $\mu\text{L}$  aflatoxin soln, 26.008, 5  $\mu\text{L}$  this aflatoxin soln + 5  $\mu\text{L}$  resolution ref. std, and 5  $\mu\text{L}$  resolution ref. std. After development, spot of individual aflatoxin std should reveal no other aflatoxins and at most only faint fluorescent spots near origin.

**26.011 Preparation and Storage of TLC Standards**

After concn and purity of each std soln are established, dil. portion of each to spotting concn (0.5  $\mu\text{g}$  aflatoxin B<sub>1</sub>, G<sub>1</sub>, or M<sub>1</sub>/mL, and 1/5 this concn for B<sub>2</sub> or G<sub>2</sub>). Use benzene-CH<sub>3</sub>CN, 26.002(a), to dil. solns of aflatoxins B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub>; to dil. soln of aflatoxin M<sub>1</sub>, use appropriate ratios of benzene and CH<sub>3</sub>CN to obtain solv. composition of (9+1). Prep. 1 mL of each at a time in g-s vol. flask. Transfer this working soln to Microflex tube, 26.001(n), for convenience in storage and dispensing.

Before storage, after aliquots have been removed for diln or spotting, weigh flasks contg std solns to nearest mg and record wts for future ref. Wrap flasks tightly in Al foil and store at 0°. When soln is to be used after storage, reweigh flask and record any change. To avoid incorporation of H<sub>2</sub>O by condensation, bring all stds to room temp. before use; do not remove Al foil from flask until contents have reached room temp.

Recheck concn stored std soln by UV detn and recheck purity each time portion is taken for diln to spotting concn. When vol. of original soln becomes less than can be employed in std photometer cell, use microcells (accurately positioned). Instrument must be recalibrated with each set of cells, since calibration includes cell pathlength. Any observed change in concn should correspond with observed loss in wt due to solv. evapn.

Std solns of B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub> are stable  $\geq 1$  year.

**26.012 Preparation of Resolution Reference Standard**

Prep. resolution ref. std by mixing aflatoxin B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub> solns, 26.008, to give concn at final diln with benzene-CH<sub>3</sub>CN (98+2) the same as those prepd individually in 26.011.

**Identification of Mycotoxins by Thin Layer Chromatography****26.013 Alternative Developing Solvents**

Samples or laboratory conditions may be encountered which result in inadequate sepns with specified TLC developing solv. Following are alternative solvs which may be useful in such situations (systems are unequilibrated unless otherwise specified):

For aflatoxins B <sub>1</sub> , B <sub>2</sub> , G <sub>1</sub> , G <sub>2</sub>	
Benzene-MeOH-HOAc	(90+5+5)
Ether-MeOH-H <sub>2</sub> O	(96+3+1)
CH <sub>2</sub> Cl <sub>2</sub> -C <sub>2</sub> HCl <sub>3</sub> - <i>n</i> -amyl alcohol-HCOOH	(80+15+4+1)
(order of R <sub>f</sub> changed to B <sub>1</sub> , G <sub>1</sub> , B <sub>2</sub> , G <sub>2</sub> )	
CHCl <sub>3</sub> -C <sub>2</sub> HCl <sub>3</sub> - <i>n</i> -amyl alcohol-HCOOH	(80+15+4+1)
	(equilibrated tank)
CHCl <sub>3</sub> -acetone-H <sub>2</sub> O	(88+12+1.5)
CHCl <sub>3</sub> -acetone-isopropanol-H <sub>2</sub> O	(88+12+1.5+1)
CHCl <sub>3</sub> -isopropanol	(99+1)
For aflatoxin M <sub>1</sub>	
Ether-MeOH-H <sub>2</sub> O	(95+4+1)
Ether-hexane-MeOH-H <sub>2</sub> O	(85+10+4+1)
For aflatoxin B <sub>2a</sub>	
CHCl <sub>3</sub> -acetone-isopropanol	(85+12.5+2.5)

*For aflatoxin M<sub>1</sub> derivative*CHCl<sub>3</sub>-MeOH-acetone-H<sub>2</sub>O (46+4+1+0.4)

See also 26.027(c).

Proportions of solvs may be varied to compensate for changes in silica gels and laboratory conditions. Increase in polar component will increase  $R_f$ .

Questionable identity of spots may sometimes be resolved by development of samples with number of different solvs. Different  $R_f$  of sample spot with reference to std spot in even 1 solv. is pos. proof of difference in identity. Coincidence of migration does not prove identity; for such proof see 26.076–26.082.

**MINICOLUMN DETECTION METHODS****Romer All Purpose Method (3)—Official First Action**

(Applicable to detection of  $\geq 5$  ppb total aflatoxins ( $B_1+B_2+G_1+G_2$ ) in almonds;  $\geq 10$  ppb total aflatoxins in white and yellow corn, peanut and cottonseed meals, peanuts, peanut butter, and pistachio nuts; and  $\geq 15$  ppb total aflatoxins in mixed feeds) (Other adoptions: American Association of Cereal Chemists Method 45-10: 1975 revisions to AACC Approved Methods.)

**26.014****Apparatus**

(a) *High-speed blender*.—See 26.001(h) (explosion-proof feature not required), or 26.001(o).

(b) *Ultraviolet light*.—Longwave UV with intensity of 430  $\mu\text{watt}/\text{cm}^2$  at 15 cm at 365 nm, or Chromatovue cabinet, 26.001(k).

(c) *Minicolumn*.—Borosilicate std wall tubing, ca 6 (id)  $\times$  190 mm, tapered at 1 end to ca 2 mm.

(d) *Minicolumn support rack*.—To hold minicolumns upright. Test tube rack may be used.

(e) *Rubber bulb*.—2 oz, with 7 mm hole in 1 end.

**26.015****Reagents**

(Deionized H<sub>2</sub>O may be used thruout.)

(a) *Solvents*.—CHCl<sub>3</sub> and acetone; tech. grade in glass may be used, except ACS grade is required for elution solv.

(b) *Potassium hydroxide wash soln*.—0.02N KOH with 1% KCl. Dissolve 1.12 g KOH pellets and 10 g KCl in 1 L H<sub>2</sub>O.

(c) *Sodium hydroxide soln*.—0.2N. 8.00 g NaOH/L.

(d) *Sulfuric acid soln*.—0.03%. Dil. 0.3 mL H<sub>2</sub>SO<sub>4</sub> to 1 L.

(e) *Precipitating reagents*.—(1) *Copper carbonate, basic*. (2) *Ferric chloride slurry*.—Mix 20 g anhyd. FeCl<sub>3</sub> (Fisher Scientific Co. No. I-89, or equiv.) with 300 mL H<sub>2</sub>O.

(f) *Diatomaceous earth*.—Hyflo Super-Cel, or equiv.

(g) *Column packings*.—(1) *Florisil*.—Fisher Scientific Co. No. F-101, 100–200 mesh. (2) *Silica gel*.—E. Merck No. 7734 (Silica Gel 60) for column chromatgy. (3) *Alumina neutral*.—Woelm, activity V, or E. Merck 100–200 mesh, Brockman activity I. (4) *Calcium sulfate, anhydrous*.—Drierite, nonindicating, 20–40 mesh (W. A. Hammond Drierite Co., Xenia, OH 45385, or equiv.). If this mesh size is not available, grind coarser mesh with mortar and pestle so that enough fines are obtained to prevent mixing of Florisil layer into Drierite layer when column is packed.

Dry packing materials 1–2 hr at ca 110°. Store all conditioned packing materials and packed columns in vapor-tight containers.

(h) *Std soln*.—See 26.006–26.011. Dil. solns of aflatoxins B<sub>1</sub> and G<sub>1</sub>, 26.008(a) or (b), with CHCl<sub>3</sub> to common soln contg final concn of 2 mg each/mL.

**26.016****Preparation of Minicolumns**

Tamp small plug of glass wool into tapered end of column. To column, add to ht indicated in following order: 8–10 mm Drierite, 8–10 mm Florisil, 16–20 mm silica gel, 8–10 mm neutral alumina, and 8–10 mm Drierite. Tamp small plug of glass wool

on top of column. Tap column after each addn and apply pressure to the glass wool at top of column with thin rod after completion. (Packed minicolumns are available from The Myco-Lab Co., PO Box 321, St. Louis, MO 63017.)

**26.017****Extraction**

Weigh 50 g sample into blender jar, add 250 mL acetone-H<sub>2</sub>O (85+15), and blend 3 min. Alternatively, use 500 mL g-s erlenmeyer and shake 45 min on mech. shaker at fast speed. Filter thru 24 cm Whatman No. 4 paper in 160 mm funnel into 250 mL graduate. Collect 150 mL filtrate and transfer to 400 mL beaker.

**26.018****Purification**

To 600 mL beaker, quant. add 170 mL 0.2N NaOH and 30 mL FeCl<sub>3</sub> slurry, and mix well. Add ca 3 g basic CuCO<sub>3</sub> to sample ext in the 400 mL beaker, mix well, and add to mixt. in 600 mL beaker. Add 150 mL diat. earth (150 mL beaker used as scoop is convenient) and mix well. Filter, using 160 mm funnel or 10 cm (id) buchner with Whatman No. 4 paper, or equiv.

Quant. transfer 150 mL filtrate to 500 mL separator; add 150 mL 0.03% H<sub>2</sub>SO<sub>4</sub> and 10 mL CHCl<sub>3</sub>. Shake vigorously ca 2 min and let sep. Transfer lower CHCl<sub>3</sub> layer (13–14 mL) to 125 mL separator. Add 100 mL KOH wash soln, (b), swirl gently 30 sec, and let sep. (If emulsion occurs, drain emulsion into 10 mL g-s graduate, add ca 1 g anhyd. Na<sub>2</sub>SO<sub>4</sub>, stopper, shake 30 sec, and let sep. (CHCl<sub>3</sub> phase need not be completely clear.) If emulsion is not broken, transfer emulsion to 125 mL separator and wash with 50 mL 0.03% H<sub>2</sub>SO<sub>4</sub>. Collect 3 mL CHCl<sub>3</sub> layer in 10 mL g-s graduate.

**26.019****Chromatography**

Transfer 2 mL CHCl<sub>3</sub> soln to minicolumn, using 5 mL syringe with 5", 15 gage needle. Let drain by gravity (15–30 min); or for faster elution, place top of column in hole of rubber bulb, hold column vertically, and apply slight air pressure to force solv. thru column at rate  $\leq 10$  cm/min until solv. appears at tip. Let rest of solv. drain by gravity. Remove bulb, if used. When solv. reaches top of adsorbent, add 3 mL elution solv., CHCl<sub>3</sub>-acetone (9+1). Let drain by gravity until solv. again reaches top of adsorbent. Do not let columns run dry during detn; aflatoxin losses may occur.

Examine columns in darkened room under UV lamp or in Chromatovue cabinet. Look for blue fluorescent band at top of Florisil layer (ca 2.5 cm from bottom of column) indicative of aflatoxin. Perform analysis with "clean" sample, and with sample "spiked" with known amt of aflatoxin (above detection limit) to obtain comparison std. Some uncontaminated samples show faint white, yellow, or brown fluorescent band at top of Florisil in sample column. If band has no definite bluish tint, sample is neg.

**Holaday-Velasco Method for Corn (4)—Official First Action**

(Applicable to detection of  $\geq 10$  ppb of total aflatoxins in white and yellow corn)

**26.020****Preparation of Sample**

See 26.049.

**26.021****Apparatus**

(a) See 26.014(a), (b), (c), and (d).

(b) *Disposable items*.—Culture tubes (20 $\times$ 150 mm) with plastic tube closures, pipets (1 mL), and plastic funnels (57 mm (2.25") top diam.).

**26.022****Reagents**

- (a) *Benzene*.—Reagent grade.  
 (b) *Methanol-water*.—Mix 800 mL MeOH with 200 mL H<sub>2</sub>O.  
 (c) *Salt soln.*—Dissolve 600 g NaCl, 600 g Zn(OAc)<sub>2</sub>, and 15 mL HOAc in 4 L H<sub>2</sub>O.  
 (d) *Chloroform-acetone*.—Mix 900 mL CHCl<sub>3</sub> with 100 mL acetone.  
 (e) *Column packing*.—See 26.015(g).

**26.023****Preparation of Column**

Plug one end of chromatgc column with pad of glass wool ca 5 mm deep. Add, in order, 5–7 mm CaSO<sub>4</sub> (granular, anhyd.), 5–7 mm Florisil, 20 mm silica gel, 10–15 mm Al<sub>2</sub>O<sub>3</sub>, and 5–7 mm CaSO<sub>4</sub>. Do not compress packing. Tap lightly between each addn to settle adsorbent and keep interfaces as level as possible. Store in vapor tight container.

**26.024****Extraction**

Blend 50 g ground and blended corn sample with 100 mL MeOH-H<sub>2</sub>O soln 1 min at high speed in blender. Filter 15 mL extract into culture tube. Add 15 mL salt soln. Close tube with plastic closure and shake vigorously 10 sec. (Small separator may be substituted for culture tube). Filter 15 mL of contents into second culture tube, add 3 mL benzene, close, and shake gently 10 sec. Let layers separate.

**26.025****Chromatography**

Pipet 1 mL benzene (upper) layer onto top of minicolumn. Let extract drain into column; then add 3 mL CHCl<sub>3</sub>-acetone, (d), and let drain. Examine column for blue fluorescent band at top of Florisil layer as in 26.019.

**QUANTITATIVE METHODS****Peanuts and Peanut Products—Official First Action****Method I (CB Method) (5)**

(Other endorsements: International Union of Pure and Applied Chemistry in IUPAC Inform. Bull. No 31, March 1968.)

**26.026****Apparatus**

See 26.001(a), (d)–(o), and in addn:

*Extractors*.—500 mL g-s erlenmeyers, or 11 L (12 qt) stainless steel pail.

**26.027****Reagents**

See 26.002, 26.008–26.012, and in addn:

(a) *Silica gel for column chromatography*.—E. Merck (Darmstadt) Silica Gel 60, 0.063–0.2 mm for 50 g samples, or 0.2–0.5 mm for 1 kg samples. Activate by drying 1 hr at 105°. Add H<sub>2</sub>O, 1 mL/100 g, seal, shake until thoroly mixed, and store ≥15 hr in air-tight container.

(b) *Silica gel for thin layer chromatography*.—Silica gel, 26.002(d), should also meet following test: Prep. aflatoxin-free ext of commodity being tested as in 26.030(a). Dissolve in 500 μL benzene-CH<sub>3</sub>CN (98+2). Place 10 μL on origin spot. To this spot, add, from solns of stds, 10 ng each of aflatoxins B<sub>1</sub> and G<sub>1</sub>, and 2 ng each of aflatoxins B<sub>2</sub> and G<sub>2</sub>. Repeat application of test spots to give ≥3 test spots evenly spaced across plate. Develop plate and examine. The 4 aflatoxins must be sepd from each other in clearly defined spots and sepd from non-aflatoxin fluorescent material in ext of commodity being examined.

(c) *Benzene-alcohol-water developing solvent*.—Prep. enough for several analyses. Shake benzene-alcohol-H<sub>2</sub>O

(46+35+19) in separator and let stand overnight at ≤22°. Then store the 2 layers that sep. in sep. g-s containers. Warm gently before use if they appear cloudy. Alternatively, use benzene-alcohol-H<sub>2</sub>O (40+6+3) for top layer and (40+27+20) for bottom layer (J. Amer. Oil Chem. Soc. 50, 1424(1973)).

**26.028****Preparation of Sample**

Peanut butter and peanut meal need no prepn for extn unless they contain large particles, in which case reduce by milling. Use hammer mill, rotary cutter, or disk (burr) type mill for meals. Grind raw and roasted peanuts and peanut butter with pieces of peanuts to paste with disk (burr) type mill before extn. See 26.003.

**26.029****Extraction**

(a) *Fifty gram sample*.—Weigh 50 g prepd sample into 500 mL g-s erlenmeyer. Add 25 mL H<sub>2</sub>O, 25 g diat. earth, and 250 mL CHCl<sub>3</sub>, and secure stopper with masking tape. Shake 30 min on wrist action shaker and filter thru fluted paper. If filtration is slow, transfer to buchner precoated with ca 5 mm layer diat. earth, 26.002(c), and use light vac. (Use vac. filtration only for slow filtering samples since evapn of CHCl<sub>3</sub> is rapid, resulting in concn of ext.) Collect first 50 mL portion CHCl<sub>3</sub> filtrate and proceed as in 26.030(a).

(b) *One kilogram sample*.—Weigh 1 kg prepd sample into 12 qt stainless steel pail. Add 500 mL H<sub>2</sub>O and mix with spatula until visually uniform. Add 5 L CHCl<sub>3</sub> and cover pail, leaving small opening for stirrer shaft. Position stirrer to achieve max. agitation without splashing. Stir 30 min; mix in 500 g diat. earth, 26.002 (c). For quant. analysis, remove enough mixt. to give 50 mL CHCl<sub>3</sub> filtrate and filter as in (a). Filter remainder thru buchner. Wash solids on funnel with 2 L CHCl<sub>3</sub>; conc. combined CHCl<sub>3</sub> filtrate and washing in rotary evaporator to ca 800 mL when sample contains fat and to ca 200 mL for low-fat meals. Add 1 L hexane-CHCl<sub>3</sub> (1+1) to concd ext. If ppt appears, filter thru layer of filter-aid in buchner, washing with 1 L hexane-CHCl<sub>3</sub> (1+1).

**26.030****Column Chromatography**

(a) *Fifty gram sample*.—Place ball of glass wool loosely in bottom of 22 × 300 mm chromatgc tube and add ca 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub> to give base for silica gel. Add CHCl<sub>3</sub> until tube is ca ½ full; then add 10 g silica gel, 26.027(a). Wash sides of tube with ca 20 mL CHCl<sub>3</sub> and stir to disperse silica gel. When rate of settling slows, drain some CHCl<sub>3</sub> to aid settling, leaving 5–7 cm above silica gel. Slowly add 15 g anhyd. Na<sub>2</sub>SO<sub>4</sub>. Drain CHCl<sub>3</sub> to top of Na<sub>2</sub>SO<sub>4</sub>. Add 50 mL sample ext to column, elute at max. flow rate with 150 mL hexane followed by 150 mL anhyd. ether, and discard. Elute aflatoxins with 150 mL MeOH-CHCl<sub>3</sub> (3+97), collecting this fraction from time of addn until flow stops.

Add few boiling chips to eluate, evap. nearly to dryness on steam bath, and quant. transfer residue to vial with CHCl<sub>3</sub>. Add 2–3 boiling chips and evap., preferably under gentle stream of N. Seal vial with hollow polyethylene stopper and cap. Save for TLC.

(b) *One kilogram sample*.—Prep. column as in (a), using 45 × 600 mm chromatgc tube, 20 g Na<sub>2</sub>SO<sub>4</sub> on glass wool ball, 100 g silica gel, 26.027(a), and 150 g Na<sub>2</sub>SO<sub>4</sub> on top of silica gel. Add sample ext to column and elute at 40–60 mL/min with 500 mL CHCl<sub>3</sub>-hexane (1+1), 1.5 L anhyd. ether, and 1 L MeOH-CHCl<sub>3</sub> (3+97). Evap. MeOH-CHCl<sub>3</sub> eluate as in (a). Retain final conc. for optional quantitation, 26.031(c), and/or preparatory sepn of aflatoxin B<sub>1</sub> for confirmation of identity by 26.076–26.082.

If cleaner ext is required for preparatory TLC, direct bioassay, or quant. assay of sample contg low levels of aflatoxin, conc. MeOH-CHCl<sub>3</sub> eluate to ca 50 mL. Transfer to 10 g silica gel (0.063–0.2 mm) column and proceed as for 50 g samples, omitting hexane elution.

Alternatively, use acid Al<sub>2</sub>O<sub>3</sub> chromatgy (JAOAC 54, 1310(1971)).

## 26.031

### Thin Layer Chromatography

(a) *Preparation of plates.*—Weigh 30 g silica gel, 26.027(b), into 300 mL g-s erlenmeyer, add amt of H<sub>2</sub>O recommended by manufacturer, shake vigorously  $\leq 1$  min, and pour into applicator. Adjust amt of H<sub>2</sub>O to obtain best consistency of slurry for spreading, as required by batch-to-batch variation in silica gel. Immediately coat five 20 × 20 cm glass plates with 0.25 mm thickness of silica gel suspension, and let plates rest undisturbed until gelled (ca 10 min). Adjust thickness of spread (and wt gel) to 0.5 mm, if necessary, to provide good resolution of aflatoxins and tightness of spots. Dry coated plates  $\geq 2$  hr at 80° or  $\geq 1$  hr at 110°, and store in desiccating cabinet with active silica gel desiccant until just before use. To prep. plate for chromatgy, scribe line 16 cm from bottom edge as solv. stop; scribe lines ca 0.5 cm in from each side or remove 0.5 cm gel from each side to prevent edge effects.

(b) *Preliminary thin layer chromatography.*—(This step may be omitted when approx. aflatoxin content is known.) Uncap vial contg sample ext, add 200  $\mu$ L benzene-CH<sub>3</sub>CN (98+2), and reseal with polyethylene stopper. Shake vigorously to dissolve, preferably with Vortex shaking machine. Puncture polyethylene stopper to accommodate needle of 10  $\mu$ L syringe. In subdued incandescent light and as rapidly as possible, spot 2, 5, and two 10  $\mu$ L spots on imaginary line 4 cm from bottom edge of TLC plate. Keep vial for quant. analysis. On same plate, spot 2, 5, and 10  $\mu$ L aflatoxin stds, 26.011. Spot 5  $\mu$ L std used on top of one of the two 10  $\mu$ L sample origin spots as internal std. Spot at least one 5  $\mu$ L resolution ref. std, 26.012, to show whether adequate resolution is attained.

Place 50 mL acetone-CHCl<sub>3</sub> (1+9) in trough of unlined developing tank. If tank is other than Thomas-Mitchell, use vol. to provide solv. depth of ca 2 cm. Composition of acetone-CHCl<sub>3</sub> can be varied from (5+95) to (15+85) to compensate for variations in silica gel and developing conditions. Use only one plate per tank, placing trough near one side to permit max. exposure of coated surface to tank vol. Immediately insert plate into tank and seal tank.

Develop plate 40 min at 23–25° or until aflatoxins reach  $R_f$  0.4–0.7. Adjust development time to compensate if different developing temp. is used. Adjust developing solv. if developing time is  $> 90$  min. Remove from tank, evap. solv. at room temp., and illuminate plate from below by placing it flat, coated side up, on longwave UV lamp in darkened room, or view plate in Chromato-Vue cabinet, or illuminate from above. (If illumination requires looking directly at lamps, protect eyes with UV-absorbing filter, such as Eastman Kodak Co. 2A.) Observe pattern of 4 fluorescent spots of resolution ref. std. In order of decreasing  $R_f$ , they are B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub>. Note small color difference (bluish fluorescence of "B" contrasted with slightly green "G" aflatoxins). Examine patterns from sample for fluorescent spots having  $R_f$  close to those of stds and similar appearances. From this preliminary plate, est. suitable diln for quant. TLC analysis. In final calcns, take into account amt of ext used for preliminary TLC.

(c) *Quantitative thin layer chromatography.*—If preliminary plate shows that new concn of sample ext is required, evap. to

dryness on steam bath and redissolve in calcd vol. benzene-CH<sub>3</sub>CN (98+2).

Spot successively 3.5, 5.0, and two 6.5  $\mu$ L portions of sample ext. All spots should be approx. same size and  $\leq 0.5$  cm diam. On same plate, spot 3.5, 5.0, and 6.5  $\mu$ L aflatoxin stds, 26.011, corresponding to aflatoxins observed on preliminary plate. Spot 5.0  $\mu$ L of each std used on top of one of the two 6.5  $\mu$ L sample origin spots as internal std. Spot at least one 5  $\mu$ L resolution ref. std, 26.012, to show whether adequate resolution is attained. Proceed as in (b).

(d) *Interpretation of the chromatogram.*—Four clearly identifiable spots should be visible in resolution ref. std.

Examine pattern from sample spot contg internal std for aflatoxin spots.  $R_f$  values of aflatoxins used as internal stds should be same as or only slightly different from those of resp. std aflatoxin spots. (Since spots from sample ext are compared directly with std aflatoxins on same plate, magnitude of  $R_f$  is unimportant. These may vary from plate to plate.)

Compare sample patterns with pattern contg internal std. Fluorescent spots in sample thought to be aflatoxins must have  $R_f$  values identical to and color similar to aflatoxin std spots when unknown spot and internal std spot are superimposed. Spot from sample and internal std combined should be more intense than either sample or std alone.

Compare fluorescent intensities of B<sub>1</sub> spots of sample with those of std spots and det. which sample portion matches one of stds. To aid in detn, move plate away from lamp to attenuate UV light so any particular pair of spots can be compared at extinction. Interpolate if intensity of sample spot is between those of 2 of std spots. If spots of smallest portion of sample are too intense to match stds, dil. sample and rechromatograph. Compare B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub> spots in same manner.

Calc. concn of aflatoxin B<sub>1</sub> in  $\mu$ g/kg from formula:

$$\mu\text{g/kg} = (S \times Y \times V) / (X \times W),$$

where  $S$  =  $\mu$ L aflatoxin B<sub>1</sub> std equal to unknown;  $Y$  = concn of aflatoxin B<sub>1</sub> std,  $\mu$ g/mL;  $V$  =  $\mu$ L of final diln of sample ext;  $X$  =  $\mu$ L sample ext spotted giving fluorescent intensity equal to  $S$  (B<sub>1</sub> std);  $W$  = g sample applied to column (10 g if 50 mL CHCl<sub>3</sub> ext is used). If final ext diln does not represent 10 g, calc. correct sample wt and substitute. The 50 mL aliquot of CHCl<sub>3</sub> ext of peanut butter or whole nuts removed for analysis in 26.029(a) or (b) usually contains 5–6 mL fat which adds to vol. Thus, 45 mL aliquot of CHCl<sub>3</sub> has been removed and ext actually represents 9 g starting material, instead of 10 g as for low-fat materials.

Calc. aflatoxins B<sub>2</sub>, G<sub>1</sub>, and G<sub>2</sub> similarly.

(e) *Thin layer chromatographic confirmation of aflatoxin G<sub>1</sub> and/or G<sub>2</sub>.*—(Applicable only when commodity, such as peanut butter, contains interferences that tend to migrate in aflatoxin G area.) If G<sub>1</sub> plus G<sub>2</sub> is  $\geq 20\%$  of total aflatoxins, confirm amt and identity of G<sub>1</sub> and G<sub>2</sub> by chromatgy, using solv. system, 26.027(c).

Respot sample and stds on silica gel plate as in (c). Put 50 mL lower phase in bottom of insulated, unlined developing tank, and 50 mL upper phase in trough. Use only 1 plate per tank, placing trough near one side to permit max. exposure of coated surface to tank vol. Without equilibrating, insert plate in trough and seal. Let solv. rise to stop line 12–14 cm above origin (30–50 min) and remove plate. In order of decreasing  $R_f$  values, resolution ref. std gives B<sub>1</sub>, B<sub>2</sub>, G<sub>1</sub>, G<sub>2</sub> as before, but many extraneous fluorescent substances found in samples will have completely different  $R_f$  values relative to those of aflatoxins in the 2 solv. systems. G<sub>1</sub> and G<sub>2</sub> aflatoxins of sample should have same  $R_f$  as those of resp. stds. Make quant. estn for G<sub>1</sub> and G<sub>2</sub> as in (c) and (d).

**Method II (BF Method) (6)**

(Other adoptions: American Oil Chemists' Society Tentative Method Ab 6-68 (revised 1973).)

**26.032****Apparatus**

See 26.001(b), (c), (g), (h), (i), (k), (l), (m), and in addn:  
Beakers.—Stainless steel, 600 mL.

**26.033****Reagents**

See 26.002(a), (b), (d), (f), 26.008–26.012.

**26.034****Preparation of Sample**

See 26.028.

**26.035****Extraction**

Weigh 100 g prepd sample of peanuts or meal or 50 g peanut butter into blender jar. Add 250 mL MeOH-H<sub>2</sub>O (55+45) and 100 mL hexane to peanut butter, and 500 mL MeOH-H<sub>2</sub>O (55+45), 200 mL hexane, and ca 4 g NaCl to peanuts or meal.

Blend 1 min at high speed. Transfer to 250 mL centr. bottle and centr. 5 min at 2000 rpm. (If time is unimportant or centrifuge is not available, let mixt. stand undisturbed in blender jar, as sepn will occur within 30 min for peanut butter and raw or roasted peanuts.)

Pipet 25 mL aq. MeOH phase into 125 or 250 mL separator, add 25 mL CHCl<sub>3</sub>, stopper, and shake 30–60 sec. Let layers sep. and drain bottom CHCl<sub>3</sub> layer into 600 mL stainless steel beaker (if available). Do not include any meal with ext. Place beaker on steam plate under stream of N and add small amt of H<sub>2</sub>O under beaker to improve heat transfer. (100 mL glass beaker is satisfactory, but more time is required for evapn.) Evap. solv. to between 2 mL and just dryness or as soon as condensing vapor is no longer visible on beaker lip. Do not leave beaker on hot plate after solv. has evapd. (Alternatively, evapn may be performed using erlenmeyers and steam bath.) Transfer ext. with careful washing, to 4 dram vial and evap. to dryness under gentle stream of N in hot H<sub>2</sub>O bath or in heating block. Dissolve ext. in 200  $\mu$ L benzene-CH<sub>3</sub>CN (98+2) for spotting on TLC plate.

**26.036****Thin Layer Chromatography and Calculations**

Proceed as in 26.031, except that no correction is required for fat carried by extg solv.

**Cocoa Beans (7)—Official Final Action**

(Other endorsements: International Union of Pure and Applied Chemistry in IUPAC Inform. Bull. Tech. Rep. No 8, August, 1973.)

**26.037****Principle**

Method I for peanuts, 26.026–26.031, is modified by preliminary hexane defatting step and by treatment of CHCl<sub>3</sub> ext with AgNO<sub>3</sub> to reduce theobromine concn.

**26.038****Apparatus**

See 26.001(a), (d), (e), (f), (g), (h), (j), (k), (l), (m), 26.004, and in addn:

Soxhlet apparatus.—To take 43  $\times$  123 mm Whatman extn thimble.

**26.039****Reagents**

See 26.002(a), (b), (d), (e), (f), 26.005–26.012, 26.027(a), and in addn:

Silver nitrate soln.—25 g/100 mL H<sub>2</sub>O.

**26.040****Preparation of Sample**

Freeze cocoa beans with liq. N. (Caution: Perform under good ventilation and wear insulated rubber gloves and face shield to protect against liq. N splashes.) Powder anal. sample in high-speed blender or grind lot samples directly in suitable app. and mix well before removing anal. sample.

**26.041****Extraction**

(Caution: See 51.011, 51.039, 51.040, 51.056, and 51.061.)

Weigh 50 g powd cocoa beans into extn thimble and defat with *n*-hexane in Soxhlet app. at siphon rate of 4–5 cycles/hr for 12–15 cycles, but  $\leq$  3 hr. (Excess extn may result in loss of aflatoxin.) Invert thimble and contents into 400 mL beaker and let dry overnight at room temp. Transfer, using powder funnel, to 500 mL g-s erlenmeyer. Scrape as much residual powder as possible from thimble with spatula. Add 25 mL AgNO<sub>3</sub> soln to sample and mix until uniform. Add 250 mL CHCl<sub>3</sub>, using portion to rinse extn thimble. Tape stopper in place. Shake 30 min on mech. shaker (low-speed setting). Filter CHCl<sub>3</sub> (lower) layer thru fluted paper and collect first 75 mL CHCl<sub>3</sub> ext. Transfer to 250 mL g-s erlenmeyer, add 7.5 mL AgNO<sub>3</sub> soln, and shake 15 min on mech. shaker. Pour mixt. into 250 mL separator and collect 50 mL CHCl<sub>3</sub> layer.

**26.042****Column Chromatography**

Prep. column and chromatograph 50 mL CHCl<sub>3</sub> layer as in 26.030(a), using flow rate of ca 10 mL/min.

**26.043****Thin Layer Chromatography**

Proceed as in 26.031(a)–(d). Note that no correction is needed for fat carried by extg solv. Sample will not be completely sol. in benzene-CH<sub>3</sub>CN spotting solv. Centr. vials to compact sediment, if needed, to avoid clogging syringe needle.

**Coconut, Copra, and Copra Meal (8)—Official First Action**

(Other endorsements or adoptions: International Union of Pure and Applied Chemistry in IUPAC Inform. Bull. Tech. Rep. No 9, August 1974; American Oil Chemists' Society Official Method Ah 1-72.)

**26.044****Apparatus**

See 26.001(a), (d), (f), (g), (h), (j), (k) (l), 26.004, and in addn:  
Funnel.—185 mm with Eaton-Dikeman No. 617 or Whatman No. 2 paper, and Whatman GF/A glass filter to fit.

**26.045****Reagents**

See 26.002(a), (b), (d), (e), (f), 26.005–26.012, and 26.027(a).

**26.046****Preparation of Sample**

Freeze copra or coconut at  $\leq$  -27.8° (-18°F). Feed continuously into hammermill at ca 450 g (1 lb)/min. Grind meal pellets in high-speed blender without freezing.

**26.047****Extraction**

Weigh 50 g sample into blender jar. Add 4 g NaCl, 100 mL H<sub>2</sub>O, and 250 mL CHCl<sub>3</sub>, and blend 3 min at high speed. Decant into 400 mL beaker. Prep. funnel by first folding paper and then placing glass filter inside folded paper. Decant ext from beaker thru funnel into 250 mL erlenmeyer. Collect 60–70 mL filtrate.

**26.048****Column and Thin Layer Chromatography**

Proceed as in 26.030(a) and 26.031(a)–(d).

**Corn (9)—Official First Action**

(Other adoptions: American Association of Cereal Chemists Method 45-05: 1972 revisions to AACC Approved Methods, pp. 1-9.)

**26.049****Preparation of Sample**

Grind entire lot sample thru hammer, Wiley, or disk mill to pass No. 14 sieve. Split sample sequentially in sample splitter, such as "riffle," until 1-2 kg portion is obtained for analysis. Retain remainder. Regrind 1-2 kg portion to completely pass No. 20 sieve. Mix reground portion thoroly in tumble blender or planetary mixer. Take anal. samples from this mix, using sample splitter. Prep. addnl portions from lot sample in same way, if needed.

**26.050****Rapid Screening**

Proceed as in **26.026-26.029(a)**, but collect second 50 mL portion  $\text{CHCl}_3$ . Evap. ext in steam bath to leave residue of corn oil. Immediately spot 5, 10, and 10  $\mu\text{L}$  warm corn oil on origin line 1.5 cm from bottom edge of plate, **26.031(a)**. Silica gel will absorb oil most readily if both oil and plate are warm and if oil is spotted immediately on completion of evapn of solv. On same plate, spot 5  $\mu\text{L}$  resolution ref. std, **26.012**. Spot 5  $\mu\text{L}$  std used on top of one 10  $\mu\text{L}$  sample ext spot as internal std. Scribe horizontal line across center of plate with pencil or other sharp object for half-plate development. (Plate can be reused after development by redrying and turning  $180^\circ$  for next spotting.) Develop plate with anhyd. ether, **26.002(f)**, in unequilibrated developing tank to scored line (<30 min). Let plate dry. Redevelop in same direction in unequilibrated tank with acetone- $\text{CHCl}_3$  (1+9) (<20 min). Adjust acetone- $\text{CHCl}_3$  ratio as needed to modify  $R_f$  of aflatoxins as in **26.031(b)**, par. 2. Observe developed plate for presence or absence of spot originating from sample and with same  $R_f$  and appearance as authentic aflatoxin  $B_1$ . Observe internal std for any change in  $R_f$  or appearance of aflatoxin caused by the ext. Observe only for presence or absence of aflatoxin  $B_1$  in sample spot.

**26.051****Determination**

Proceed as in **26.026-26.031**.

**Cottonseed Products****Rapid Modification (10)—Official First Action****26.052****Apparatus**

See **26.001(k)**, **(l)**, **(m)**, **(n)**, and in addn:

(a) *Butt tube*.—32  $\times$  125 mm. (Similar to chromatgc tube but without stopcock.)

(b) *Chromatographic tubes*.—22 (id)  $\times$  500 mm, with Teflon valve (Corning Glass Works No. 2145 or Kimble Products No. 17800, or equiv.).

(c) *Densitometer*.—See **26.001(e)**.

**26.053****Reagents**

See **26.002(a)**, **(b)**, **(c)**, **(d)**, **(e)**, **(f)**, and in addn:

(a) *Solvents*.—Reagent grade  $\text{CH}_2\text{Cl}_2$ , anhyd. ether ( $\leq 0.01\%$  EtOH), and hexane (bp 68-69°).

(b) *Lead acetate soln*.—Dissolve 200 g  $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  with warming, add 3 mL HOAc, and dil. to 1 L.

(c) *For column chromatography*.—(1) *Silica gel*.—See **26.027(a)**. (2) *Wash solvents*.—Benzene-HOAc (9+1); ether-hexane (3+1). (3) *Aflatoxin elution solvent*.— $\text{CHCl}_3$ -acetone (4+1).

(d) *Acidic alumina*.—Fisher A-948, 80-200 mesh. Add 3%  $\text{H}_2\text{O}$  by wt, shake well, and equilibrate overnight.

(e) *Aflatoxin stds*.—See **26.006-26.012**.

**26.054****Preparation of Sample**

Grind whole seed or kernels in Wiley mill, or equiv., to pass No. 10 sieve. For seed contg lint, screen ground sample on  $\frac{1}{64}$ " screen to remove coarse lint. Grind meals to pass No. 18 sieve. Quarter or riffle ground sample to obtain 50-100 g anal. sample.

**26.055****Extraction**

(a) *Meats (kernels) and conventional meals*.—Weigh 25 g sample into 500 mL erlenmeyer, add 250 mL acetone- $\text{H}_2\text{O}$  (85+15), and stopper with leakproof glass or polyethylene stopper. Shake vigorously 30 min on mech. shaker. Alternatively, weigh 25 g sample into 1 L blender jar, add 250 mL acetone- $\text{H}_2\text{O}$  (85+15), and blend 2 min at low speed and 3 min at high speed.

Filter thru folded 18.5 cm Whatman No. 4 paper, or equiv., collecting  $\geq 100$  mL filtrate.

(b) *Ammoniated meals*.—Weigh 25 g sample, add 40 mL 0.1N HCl, and let soak 5 min. Add 210 mL anhyd. acetone, and ext and filter as in (a).

**26.056****Purification**

Measure 100 mL filtrate into 250 mL beaker, add 80 mL  $\text{H}_2\text{O}$  and 20 mL 20%  $\text{Pb}(\text{OAc})_2$  soln, (b), stir well, and let stand ca 5 min to coagulate ppt. Add ca 5 g filter-aid, **26.002(c)**, stir well, and filter thru folded 18.5 cm Whatman No. 4 paper, or equiv., collecting  $\geq 100$  mL filtrate.

Ext 100 mL filtrate with 50 mL  $\text{CH}_2\text{Cl}_2$  in 250 mL separator, shaking vigorously 1 min, and let sep. Prep. Butt tube with loose plug of glass wool in constriction, cover with ca 2 cm anhyd. granular  $\text{Na}_2\text{SO}_4$ , and add 5 g acidic alumina (5 mL beaker filled to top), 5 g silica gel 60 for column chromatgy (10 mL beaker filled to top), and ca 2 cm  $\text{Na}_2\text{SO}_4$ . Drain  $\text{CH}_2\text{Cl}_2$  (lower) layer thru tube, collecting filtrate in clean 250 mL beaker. Repeat with addnl 50 mL  $\text{CH}_2\text{Cl}_2$ , and finally wash tube with 50 mL  $\text{CH}_2\text{Cl}_2$ -acetone (9+1). Evap. combined eluates to dryness on steam bath. Do not overheat dry ext.

(a) *Meats and conventional meals*.—Transfer quant. with  $\text{CH}_2\text{Cl}_2$  to 2 dram vial, evap. to dryness under N, and reserve for preliminary TLC. If desired, ext may be cleaned up further by **26.057**, but omit benzene-HOAc (9+1) wash with nonammoniated cottonseed products.

(b) *Ammoniated meals*.—Dissolve dry ext in ca 3 mL  $\text{CH}_2\text{Cl}_2$  and proceed as in **26.057**.

**26.057****Column Chromatography**

Place small wad of glass wool in constriction of chromatgc tube, and add ca 2 cm  $\text{Na}_2\text{SO}_4$ . Slurry 10 g silica gel for column chromatgy with ca 40 mL ether-hexane (3+1) in 50 mL beaker, and pour into tube. Wash beaker with ca 25 mL ether-hexane (3+1), and add to tube. When gel settles, carefully top with ca 2 cm layer of  $\text{Na}_2\text{SO}_4$ . Drain solv. to top of  $\text{Na}_2\text{SO}_4$  layer.

Add  $\text{CH}_2\text{Cl}_2$  soln of ext to column, washing beaker with 2 ca 3 mL portions  $\text{CH}_2\text{Cl}_2$ ; add to column. When solv. level reaches top of  $\text{Na}_2\text{SO}_4$ , add 100 mL benzene-HOAc (9+1) and drain to top of  $\text{Na}_2\text{SO}_4$ . Add 150 mL ether-hexane (3+1) and drain to top of  $\text{Na}_2\text{SO}_4$ . Discard washes. Elute aflatoxins with 200 mL  $\text{CHCl}_3$ -acetone (4+1), collecting eluate in clean 250 mL beaker. Evap. to dryness on steam bath, transfer quant. with  $\text{CH}_2\text{Cl}_2$  to 2 dram vial, evap. to dryness under N, and reserve for preliminary TLC.

**26.058****Preliminary Thin Layer Chromatography**

See **26.031(a)** and **(b)**.

Dissolve dry ext from **26.056** or **26.057** in exactly 0.5 mL benzene- $\text{CH}_3\text{CN}$  (98+2), and proceed as in **26.031(b)**, except that

plate is developed 20 min and sample wt,  $W$ , is 5 g. After quantitation, confirm identity as follows:

Spray plate with fine mist of  $H_2SO_4$  (1+3) and view under longwave UV. Aflatoxins  $B_1$  and  $B_2$  should now have yellow fluorescence, and  $G_1$  and  $G_2$ , yellow-blue fluorescence. While  $G$  aflatoxins are rarely found in cottonseed, blue fluorescent spots sometimes found in cottonseed exts at or near  $R_f$  of  $G_1$  or  $G_2$  will not exhibit characteristic color change. Test is not confirmatory, but will rule out presumptive aflatoxins which do not show color change.

#### 26.059 Quantitative Thin Layer Chromatography

Evap. remaining ext from 26.058 and dissolve in appropriate vol. benzene- $CH_3CN$  (98+2) as in (a), for either visual or densitometric analysis.

(a) *Sample dilution and aliquots for visual and densitometric analysis.*—See Table 26.03.

Table 26.03 Aliquots for visual and densitometric analysis

Approx. $B_1$ Content from Prelim. TLC, $\mu g/kg$	Visual Analysis		Densitometric Analysis	
	Diln of Ext, mL	Aliquots on Plate, $\mu L$	Diln of Ext, mL	Aliquots on Plate, $\mu L$
0–10	0.125	3–5–7	0.125	10–10
10–25	0.125	3–5–7	0.125	5–5
25–50	0.50	3–5–7	0.25	6–6
50–75	0.75	3–5–7	0.50	6–6
75–125	1.00	3–5–7	0.50	5–5
125–150	1.25	3–5–7	0.75	5–5
150–175	1.50	3–5–7	1.00	6–6
175–200	2.00	3–5–7	1.25	6–6

(b) *Visual analysis.*—Spot 3, 5, and 7  $\mu L$  sample ext on plate, along with 2, 3, 4, and 5  $\mu L$  aflatoxin std, 26.011. Spot and develop plates as in 26.031(b). Interpret chromatogram as in 26.031(d).

(c) *Densitometric analysis.*—Spot suggested sample aliquots, (a), on plate, along with duplicate aliquots of mixed aflatoxin std to provide 5 ng aflatoxin  $B_1$  and  $G_1$ , and 1 ng  $B_2$  and  $G_2$ /spot. Also adjust sep. sample aliquots to these values for  $B_2$ ,  $G_1$ , and  $G_2$  by dilg, and spot sep. Place spots along imaginary line ca 4 cm from bottom of plate. Develop as in 26.031(b). Do not damage gel layer during spotting, as significant errors may be introduced. If plate is visually inspected before densitometry, use low wattage UV source and min. exposure time.

Scan plate with densitometer according to instructions of manufacturer. Irradiate with 365 nm source: observe for emission at 420–460 nm.

Calc. concn of aflatoxin  $B_1$  in  $\mu g/kg$  as follows:

$$\mu g/kg = (B \times Y \times S \times V) / (Z \times X \times W),$$

where  $B$  = av. area aflatoxin  $B_1$  peaks in sample aliquots;  $Y$  = concn aflatoxin  $B_1$  std,  $\mu g/mL$ ;  $S$  =  $\mu L$  aflatoxin  $B_1$  std spotted;  $V$  = final diln of sample ext,  $\mu L$ ;  $Z$  = av. area aflatoxin  $B_1$  peaks in std aliquots;  $X$  =  $\mu L$  sample ext spotted;  $W$  = g sample represented by final ext (10 g if 25 g sample used for analysis).

Repeat calcn for each of other aflatoxins observed.

Correct aflatoxin concn values from densitometric measurement for amt of sample ext removed for either Preliminary TLC, 26.058, or Visual analysis, (b), if used before densitometric measurements, as follows:

$$\text{Corrected } \mu g/kg = \frac{\text{apparent } \mu g/kg}{1 - [(p/P) + (q/Q)]},$$

where  $p$  = total  $\mu L$  sample ext spotted in 26.058;  $P$  =  $\mu L$  sample ext prep'd in 26.058;  $q$  = total  $\mu L$  sample ext spotted in (b) (if

done prior to densitometric analysis);  $Q$  =  $\mu L$  sample ext prep'd for (b) (if done prior to densitometric analysis).

#### 26.060 TLC Confirmation of Aflatoxin $G_1$ and/or $G_2$

Aflatoxins  $G_1$  and  $G_2$  are rarely observed in cottonseed products, but some exts may contain bluish fluorescent non-aflatoxin spot at or near  $R_f$  of  $G_1$  or  $G_2$ , depending on TLC conditions. If  $G_1$  or  $G_2$  is judged to be present, confirm by respotting two 5  $\mu L$  aliquots of sample ext on new plate. Spot 5  $\mu L$  aflatoxin std on top of one sample aliquot and develop plate in 150 mL  $CHCl_3$ -MeOH (95+5). Although aflatoxins are not well resolved in this solv., bluish fluorescent nonaflatoxin component will be resolved from aflatoxins  $G_1$  and  $G_2$  as indicated by comparison of sample aliquots with and without internal std.

#### Green Coffee (17)—Official First Action

##### 26.061

##### Apparatus

See 26.001(b), (c), (d), (h), (i), (k), (m), and (n).

##### 26.062

##### Reagents

See 26.002(a), (b), (d), (e), (f), 26.008–26.012, and in addn:

(a) *Tetrahydrofuran (THF).*—(Caution: See 51.070.) Purify by passing 250 mL THF thru 25 g Woelm neut. alumina to remove peroxides. Adjust proportionately for larger vols of THF.

(b) *Deactivated Florisil.*—60–100 mesh, preactivated at 1200° (Fisher Scientific Co. No. F-100), washed and deactivated as follows: Wash 500 g Florisil in chromatgc tube with 1 L  $n$ -hexane-HOAc (99+1) and rinse with 500 mL  $n$ -hexane to remove excess HOAc. Place in flat tray and dry in fume hood to remove solvs; then dry overnight in oven at 120–135°. Remove from oven, place in desiccator, and cool to room temp. Use proportionate amts of solv. to prep. less Florisil. (Acid-washed Florisil can be stored indefinitely.) Place ca 100 g washed Florisil in airtight, g-s reagent bottle ca  $\frac{2}{3}$  full, add 10% (w/w)  $H_2O$ , and shake vigorously by hand ca 5 min and then on mech. shaker 1 hr; let Florisil- $H_2O$  equilibrate overnight. Prep. deactivated Florisil only in 100 g amts and use within 1 week.

(c) *Neutral alumina.*—Woelm (ICN Pharmaceuticals, Inc., Life Sciences Group).

##### 26.063

##### Preparation of Sample

Freeze green coffee beans with solid  $CO_2$  or liq. N and grind to fine powder in high-speed blender.

##### 26.064

##### Extraction

Weigh 25 g powd green coffee beans in 500 mL g-s erlenmeyer, add 12.5 mL  $H_2O$  and 125 mL  $CHCl_3$ , and shake 30 min on mech. shaker. Transfer to centr. bottle and centr. 10 min at 2000 rpm. Use 50 mL aliquot of  $CHCl_3$  layer for Florisil column cleanup.

##### 26.065

##### Florisil Chromatography

Place glass wool plug loosely in bottom of 22 × 300 mm chromatgc tube, add ca 5 g anhyd.  $Na_2SO_4$  to form even base, and add 100 mL  $CHCl_3$ ; then add 5 g washed and deactivated Florisil with stirring to disperse Florisil and prevent air entrapment. Let Florisil settle and drain  $CHCl_3$ , leaving ca 7.5 cm above Florisil; then slowly add 15 g anhyd.  $Na_2SO_4$ . Rinse sides of column and drain  $CHCl_3$  to top of  $Na_2SO_4$ ; then add 50 mL sample ext. Wash column with 150 mL purified THF at ca 10 mL/min and discard wash. Elute aflatoxins with 300 mL acetone-MeOH (9+1) at  $\leq 10$  mL/min into 500 mL erlenmeyer. Transfer acetone-MeOH fraction to r-b flask and evap. to dryness on

steam bath under N. Quant. transfer residue to small vial with  $\text{CHCl}_3$ , evap. to dryness on steam bath under N, and reserve for TLC.

#### 26.066 *Thin Layer Chromatography*

Proceed as in 26.031(a), (b), (c), and (d), except use benzene-alcohol- $\text{H}_2\text{O}$  developing solv., 26.027(c).

#### Pistachio Nuts (12)—Official First Action

##### 26.067 *Method I*

Weigh 50 g nutmeats or equiv. from 26.003 (100 g in-shell or 100 g nutmeats and oyster shell) into 1 L g-s erlenmeyer, add 50 mL  $\text{H}_2\text{O}$ , 50 g diat. earth, and 500 mL  $\text{CHCl}_3$ , and secure stopper with tape. Proceed as in 26.029(a), beginning "Shake 30 min . . .", 26.030(a), and 26.031.

##### 26.068 *Method II*

Weigh 50 g nutmeats or equiv. from 26.003 (100 g in-shell or 100 g nutmeats and oyster shell) into blender jar and add 500 mL  $\text{MeOH-H}_2\text{O}$  (55+45), 200 mL hexane, and ca 4 g NaCl. Proceed as in 26.035, par. 2, using 50 mL aq.  $\text{MeOH}$  phase, 250 mL separator, and 50 mL  $\text{CHCl}_3$  in par. 3.

#### Soybeans (9)—Official First Action

##### 26.069 *Determination*

Prep. sample as in 26.049 and proceed as in 26.026–26.031 for detn. Because of oil in original  $\text{CHCl}_3$  ext,  $W$  (g original soybean sample represented by final purified ext) = 9.6 g.

#### Eggs (13)—Official First Action

(Caution: See 51.046, 51.054, 51.056, and 51.073.)

##### 26.070 *Apparatus*

See 26.001(e) and in addn:

(a) *Explosion-proof blender*.—Waring Model EP-1, or equiv., with 1 L jar and cover. (See 26.001(h).) Control speed with variable transformer.

(b) *Butt tube*.—32 × 200 mm (Corning Glass Works No. 92195, or equiv.).

(c) *Thin layer plates*.—10 × 10 or 20 × 20 cm plates coated with 0.25–0.5 mm (wet thickness) layer of Macherey-Nagel GHR silica gel for TLC (Macherey, Nagel & Co., 516 Duren, Germany, distributed by Brinkmann Instruments, Inc.) dried 1 hr at 105° or Adsorbosil-1 silica gel for TLC (Applied Science Laboratories, Inc.), or equiv.

(d) *Development tank*.—Glass tank with ground-to-fit cover and metal trough, or equiv. Use silicone grease seal.

(e) *Viewing cabinet*.—Chromato-Vue Model C-6 (Ultra-Violet Products, Inc.), or equiv., fitted with 15 watt longwave UV lamp.

(f) *Sample vial*.—2 dram, with foil-lined screw cap. See 26.001(m).

##### 26.071 *Reagents*

See 26.002(c), (e), (f), 26.053(b), and in addn:

(a) *Sodium chloride soln*.—ACS grade, satd soln (ca 40 g/100 mL  $\text{H}_2\text{O}$ ).

(b) *Silica gel*.—E. Merck silica gel 60 (No. 7734), 0.063–0.200 mm (70–230 mesh), or equiv. Activate by drying 1 hr at 105°, add 3 mL  $\text{H}_2\text{O}$ /100 g, seal in jar, shake until mixed thoroly, and store overnight before use.

(c) *Aflatoxin reference std.*—Prep. as in 26.004–26.011 to contain 0.50  $\mu\text{g}$  aflatoxin  $\text{B}_1$ /mL benzene- $\text{CH}_3\text{CN}$  (98+2). Store dild stds in refrigerator in leak-proof container.

##### 26.072 *Extraction and Lipid Removal*

Weigh amt liq. or powd egg and add  $\text{H}_2\text{O}$  into blender jar, as indicated in Table 26.04. Add 42 mL satd NaCl soln, and blend 1 min at moderate speed (variable transformer set at 40 v). Add 300 mL acetone and blend addnl 3 min. Filter thru folded paper into 250 mL graduate.

Table 26.04 Preparation of Sample of Egg Products

Egg Product	% $\text{H}_2\text{O}$	Sample Wt, g	$\text{H}_2\text{O}$ Added before Extn, mL	Sample Equiv. in Final Ext, g
Whole egg	74	100	0	45
Egg white	88	100	0	44
Egg yolk	51	100	20	46
Dried whole egg	5	27	73	12.2
Dried egg yolk	4	27	73	12.2
Dried egg white	9	28	72	12.7

Transfer 235 mL filtrate to 500 mL erlenmeyer. Add 20 mL  $\text{Pb}(\text{OAc})_2$  soln and 150 mL  $\text{H}_2\text{O}$ . Stir and let stand ca 5 min. Add 10 g diat. earth, stir, and filter thru paper into clean 500 mL graduate. If first filtrate is cloudy, refilter thru same paper.

Transfer 325 mL filtrate to 500 mL separator with Teflon plug and stopper; add 100 mL pet ether, and shake vigorously ca 1 min. Let layers sep., drain lower aq. layer into another 500 mL separator, and discard upper pet ether layer. Add 50 mL  $\text{CHCl}_3$  to aq. layer, shake separator vigorously ca 1 min, and let layers sep.

##### 26.073 *Column Chromatography*

Prep. Butt tube column by inserting loose plug of glass wool in constriction; add ca 2 cm bed of anhyd.  $\text{Na}_2\text{SO}_4$  followed by 10 g silica gel slurried in 50 mL  $\text{CHCl}_3$ . Drain  $\text{CHCl}_3$  and add another 2 cm bed of anhyd.  $\text{Na}_2\text{SO}_4$  on top of drained silica gel.

Filter lower  $\text{CHCl}_3$  layer from separator thru Butt tube, collecting filtrate in clean 300 mL erlenmeyer. Add 20 mL acetone to aq. layer, and ext with second 50 mL portion of  $\text{CHCl}_3$ . Filter lower  $\text{CHCl}_3$  layer thru same Butt tube; follow with 20 mL  $\text{CHCl}_3$ -acetone (9+1).

Evap. combined filtrate and washings to near dryness on steam bath, quant. transfer ext to 2 dram vial, and evap. to dryness on steam bath under N stream. Avoid overheating of dry ext. Reserve for TLC. Final ext represents wt egg product indicated in Table 26.04.

Example: Whole egg (74%  $\text{H}_2\text{O}$ )

$$\text{Wt egg} = 100 \text{ g} \times [235 / (300 + 42 + 74)] \times [325 / (235 + 20 + 150)] = 45 \text{ g}$$

##### 26.074 *Thin Layer Chromatography*

(Perform TLC analysis without delay. Aflatoxins are unstable on silica gel when exposed to air, light, and moisture.)

Add 100  $\mu\text{L}$  benzene- $\text{CH}_3\text{CN}$  (98+2) to dry sample residue in vial, cap, and shake vigorously ca 1 min on vortex shaker. For screening analysis, use 10 × 10 cm TLC plate scored and spotted as shown in Fig. 26.01, using 20  $\mu\text{L}$  ext soln and 2  $\mu\text{L}$  aflatoxin  $\text{B}_1$  std soln. If sample is pos., respot ext for quantitation on 20 × 20 cm plate as shown in Fig. 26.01. Take precaution to avoid loss of solv. from ext during spotting, i.e., hold vial at top to reduce heating from hands; immediately close vial upon removing each 10  $\mu\text{L}$  portion. Spot second plate as above and overspot sample spot with 1 ng aflatoxin  $\text{B}_1$  as internal std.

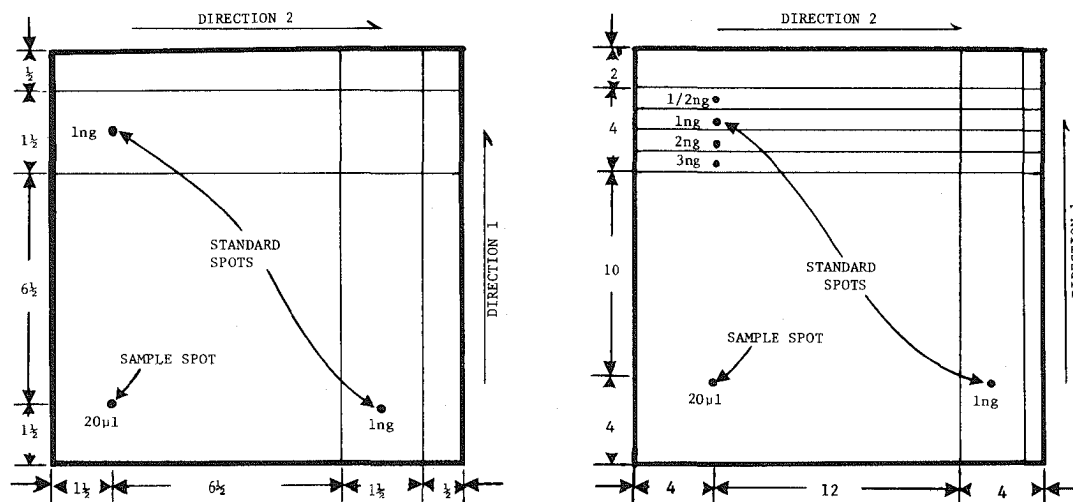

Fig. 26:01—Spotting and scoring patterns for 2-dimensional TLC plates: left, miniplates 10 × 10 cm; right, full plates 20 × 20 cm (all dimensions in cm)

(Internal std plate may be omitted if aflatoxin B<sub>1</sub> R<sub>f</sub> area is free of artifact spots.) Reserve remaining ext in freezer for confirmation of aflatoxin identity, if detected.

Develop plates in first direction with anhyd. Et ether-MeOH-H<sub>2</sub>O (96+3+1) in sep., well-sealed, unequilibrated tanks. Remove plates from tanks and dry in forced-draft oven 1 min at 50°. Cool ca 1 min and immediately develop in second direction with acetone-CHCl<sub>3</sub> (1+9). Evap solv. at room temp. and observe in dark under longwave UV light. Look for aflatoxin B<sub>1</sub> at intersection of projected imaginary lines from std aflatoxin B<sub>1</sub> spots in side channels across each direction of development. If aflatoxin B<sub>1</sub> is thought to be present, compare plates with and without internal std. For pos. samples, aflatoxin B<sub>1</sub> from sample plus added internal std are perfectly superimposed, combination spot fluorescence is more intense than that of sample or 1 ng ref. std alone, and no. of spots on both plates is same.

If aflatoxin B<sub>1</sub> is present, quantitate visually as in 26.031 or by densitometry as follows: Carefully cover sample plate with clean glass plate to avoid damage to silica gel layer. Sep. the 2 plates, if necessary, with narrow strips of masking tape placed along plate edges. Mark aflatoxin B<sub>1</sub> spot from sample by placing small piece of masking tape with lines 1 cm apart parallel to direction to be scanned and ca 1 cm removed from aflatoxin B<sub>1</sub> spot. Select direction of scan to coincide with long dimension of aflatoxin B<sub>1</sub> spot. Scan stds as in 26.059; then position aflatoxin B<sub>1</sub> sample spot, guided by markings on masking tape, and scan. Alternative methods for locating aflatoxin B<sub>1</sub> spots, some of which obviate need to cover plate, may also be used. Check instrumental response of the 3 std spots for linearity by plotting response against concn or by performing ratio calcn. Calc. µg aflatoxin B<sub>1</sub>/kg as in 26.059(c).

#### 26.075

#### Confirmation of Identity

Occasionally, blue fluorescent spots appear which can easily be mistaken for aflatoxin B<sub>1</sub>. Therefore, chem. confirmation of identity of toxin from all pos. samples is essential. Spot ext equiv. to 9 g eggs for 2-dimensional chromatgy as in 26.074 (see Fig. 26:01). Spot 3 µL aflatoxin B<sub>1</sub> std soln in each of 2 ref. channels, 1 for each direction of development. Add 2 µL trifluoroacetic acid (TFA) to each sample and std aflatoxin B<sub>1</sub> spot on plate, using glass capillary pipet, and let stand in dark 5 min at room temp. Dry in forced-draft oven 10 min at ca 45° or blow warm air (temp. of air at plate surface, 35–40°) 10 min from 30

cm above plate. (Hot air blower, Master Appliance Corp., 2512-18th St, Racine, WI 53403, or hair dryer, is convenient.) Let plate cool, and develop in first direction with anhyd. Et ether-MeOH-H<sub>2</sub>O (96+3+1). Dry in forced-draft oven 1 min at 50°, cool, and develop in second direction with CHCl<sub>3</sub>-acetone-isopropanol (85+12.5+2.5). Examine chromatogram. For pos. confirmation of identity of aflatoxin B<sub>1</sub>, look for formation of new blue fluorescent spot, aflatoxin B<sub>2a</sub>, in sample at R<sub>f</sub> ca 0.3 positioned at intersection of imaginary lines projected from ref. stds perpendicularly across direction of each development. For most eggs, yellow fluorescent spot is present with R<sub>f</sub> only slightly different from that of aflatoxin B<sub>2a</sub> and should not be confused with aflatoxin B<sub>2a</sub> spot to give erroneous pos. confirmation.

#### Identification of Aflatoxin B<sub>1</sub> by Derivative Formation (14) Official First Action

#### 26.076

#### Apparatus

- Chromatographic tubes.**—See 26.001(d), 22 × 300 mm.
- Thin layer plate scraper.**—(Fig. 26:02.) Adapt from sealing tube with fritted disk (Corning Glass Works No. 39580, 30 M, or equiv.).
- Vials.**—1/2, 1, and 4 dram, screw cap (Kimble Products No. 60910-L, but foil-lined, or equiv.).

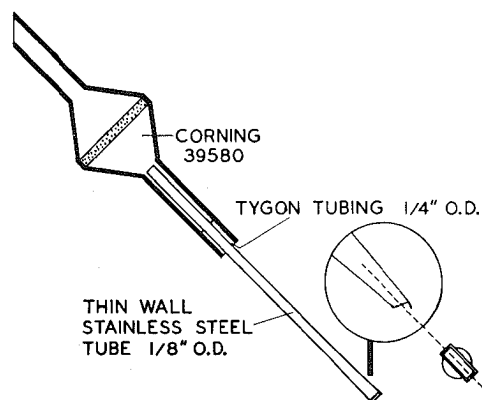

FIG. 26:02—Plate scraper for removing adsorbent from TLC plates

(d) *Micro bell jar with suction side arm*.—Corning Glass Works 6880, or equiv.

(e) *Thin layer chromatographic apparatus*.—See 26.001(k).

(f) *Pipets*.—Pasteur disposable.

(g) *Distilling apparatus*.—All-glass 24/40 joints, with one 250 mL r-b flask; two 100 mL r-b flasks; Claisen distilling head-condenser; and flask adapter with side arm for drying tube attachment.

## 26.077

## Extraction

See 26.029(a) and (b). Sample ext should contain  $\geq 2$   $\mu$ g aflatoxin B<sub>1</sub>. If preparatory TLC is being used to obtain material for bioassay, 26.084–26.089, aflatoxin B<sub>1</sub> in ext should be  $\geq 30$   $\mu$ g.

## 26.078

## Column Cleanup

Proceed as in 26.030(a) and (b), if addnl cleanup is needed for preparatory TLC.

## 26.079

## Preparative TLC

Prep. plates and use TLC technic as in 26.031.

Dissolve residue from column cleanup in 250  $\mu$ L CHCl<sub>3</sub>. Transfer CHCl<sub>3</sub> soln to origin line of TLC plate, using 10  $\mu$ L per spot at 5 mm spot intervals. About 1 cm beyond each spot at either end, place 5  $\mu$ L spot of resolution ref. std which will also serve for locating line of aflatoxin B<sub>1</sub> spots.

Develop plate and examine. Expose plate to lowest intensity UV light required to see fluorescent spots. Keep time and intensity of irradiation by UV light at min. With needle, mark off area contg aflatoxin B<sub>1</sub>. Collect silica gel from marked off area, using suction to pull coating loosened by plate scraper into filter portion of device. Elute aflatoxin from silica gel by swirling with six 5 mL portions MeOH-CHCl<sub>3</sub> (1+2). Use filter bell to pull MeOH-CHCl<sub>3</sub> thru fritted glass into 50 mL erlenmeyer by suction. Evap. solv. to dryness on steam bath under N stream. Dissolve residue in enough benzene-CH<sub>3</sub>CN (98+2) to give estd aflatoxin B<sub>1</sub> concn of 1  $\mu$ g/mL.

Det. purity and amt of aflatoxin B<sub>1</sub> in residue as in 26.031(c) and (d). If spots other than aflatoxin B<sub>1</sub> are present, repeat preparative TLC until aflatoxin B<sub>1</sub> is chromatgc pure. Est. amt of aflatoxin B<sub>1</sub> collected by comparison with spots of TLC std. Calc. aflatoxin B<sub>1</sub> from equation:

$$\mu\text{g} = (S \times Y \times V) / (X \times 1000),$$

where symbols are same as in 26.031(d).

Use residue soln for prepn of derivatives by 26.080.

## 26.080

## Preparation of Derivatives

Transfer ext contg 1  $\mu$ g aflatoxin B<sub>1</sub> to 1 dram vial, remove CHCl<sub>3</sub> by evapn under N on steam bath, and dissolve residue in 1.0 mL benzene-CH<sub>3</sub>CN (98+2). Transfer vol. benzene-CH<sub>3</sub>CN soln calcd to contain 0.25  $\mu$ g aflatoxin B<sub>1</sub> to 2 sep. 0.5 dram vials. Add 100  $\mu$ L H<sub>2</sub>O and 1 drop HCl to vial 1 and 250  $\mu$ L Ac<sub>2</sub>O and 1 drop HCl to vial 2. Use disposable pipets for adding drops. Close vials with Teflon or Al foil-lined caps, shake both vials vigorously, and heat 10 min on steam bath with occasional agitation. Evap. to dryness on steam bath under N.

For controls, prep. 2 derivatives, as above, using 0.1  $\mu$ g portions aflatoxin B<sub>1</sub> from std soln, 26.011.

## 26.081

## Thin Layer Chromatography

Dissolve each derivative in the 4 vials in 20  $\mu$ L benzene-CH<sub>3</sub>CN (98+2). Using 10  $\mu$ L syringe, transfer 10  $\mu$ L of each derivative soln to origin spots at ca 2 cm intervals on activated TLC plate

in following sequence: vial 1 reaction product, vial 1 control, vial 2 reaction product, vial 2 control, 20 ng presumptive aflatoxin from original ext, 20 ng unmodified std aflatoxin B<sub>1</sub>, and resolution ref. std.

Develop plate as in 26.031(b).

Reactions should produce *dominant* characteristic fluorescent spots. *R<sub>f</sub>* values for these spots fluctuate; compare with derivatives prepd from std B<sub>1</sub>.

Acid-catalyzed reaction with H<sub>2</sub>O produces single, characteristic spot at *R<sub>f</sub>* ca 10% of that of unreacted aflatoxin.

Acid-catalyzed reaction with Ac<sub>2</sub>O produces 2 characteristic spots of ca equal size but of different intensity, migrating close to or slightly behind aflatoxin B<sub>1</sub>-G<sub>2</sub> area. Lower *R<sub>f</sub>* spot is brighter of the two.

## 26.082

## Record

Illuminate developed plate with longwave UV lamp used for viewing. Photograph plate, using 200 (ASA) speed Polaroid black and white film. Operate camera with Kodak 3A lens filter, or equiv., cutting off all light below 380 nm, and lens opening *f*/4.6 and shutter speed of 5 sec, or other combination of lens opening and shutter speed which produces proper exposure (e.g., 2000 (ASA) speed Polaroid film, 0.5 sec exposure, *f*/4.6). Cover developed area of plate with black mask, add legend strip to identify each spot, and superimpose legend on original picture by double exposure, using white light for second exposure.

## 26.083

## Identification of Aflatoxin by Derivative Formation on TLC Plate (15)—Official First Action

Divide silica gel plate, 26.031(a), in 2 equal vertical sections by scoring thick line down plate. Cover one section with clean glass plate. On uncovered side, spot two 1–10  $\mu$ L aliquots of sample ext prepd for TLC contg 0.5–5 ng aflatoxin B<sub>1</sub> and/or G<sub>1</sub>. On 1 of these spots add same amts B<sub>1</sub> and G<sub>1</sub> stds as in sample spot; also place on plate sep. spot contg same amts of these stds. To ext, ext plus stds, and stds spot, add 1  $\mu$ L trifluoroacetic acid (TFA), and let react 5 min. Blow warm air (temp. of air at plate surface 35–40°) over plate  $\geq 10$  min. (Hot air blower, Master Appliance Corp., 2420–18th St, Racine, WI 53403, or hair dryer, is convenient.) All TFA must be removed; otherwise second front forms in TLC. Uncover second section of plate and spot same as first, but do not add TFA.

Develop plate in CHCl<sub>3</sub>-acetone (85+15) or EtOAc satd with H<sub>2</sub>O. Pour 50 mL solv. directly into tank. Place trough or 3 small beakers with H<sub>2</sub>O in front of plate. Do not equilibrate.

After development, examine plate under longwave UV light. Unreacted aflatoxin appears near top of plate on section without TFA. Blue fluorescent derivatives (B<sub>2a</sub> and G<sub>2a</sub>) appear at *R<sub>f</sub>* ca 1/4 that of B<sub>1</sub> and G<sub>1</sub>. If *R<sub>f</sub>* of anticipated derivative spots is  $< 0.25$ , increase polarity of developing solv. and repeat with fresh plate. Presence of aflatoxins B<sub>2a</sub> and/or G<sub>2a</sub> in reacted sample ext channel, established by comigration with superimposed stds, is proof of identity of aflatoxin B<sub>1</sub> and/or G<sub>1</sub> in sample ext. Also examine plate under shortwave UV light, which often discloses spurious spots in aflatoxins areas, especially in G areas. Any spot which shows increase in fluorescent intensity under shortwave UV light over that under longwave UV light is not aflatoxin.

Spray plate with H<sub>2</sub>SO<sub>4</sub> (1+3), which changes aflatoxin fluorescence from blue or blue-green to yellow. This test only confirms absence of aflatoxins; i.e., spots which do not turn yellow are positively not aflatoxin, whereas many materials other than aflatoxin may give yellow spot with H<sub>2</sub>SO<sub>4</sub>.

### Chicken Embryo Bioassay for Aflatoxin B<sub>1</sub> Toxicity (16) Official Final Action

#### 26.084

#### Apparatus

(Decontaminate all syringes, needles, vials, and other app. which have been in contact with aflatoxin B<sub>1</sub> by soaking in 5% NaOCl soln before disposal or cleaning.)

(a) *Egg candling light*.—60 watt candler (Speed King; Schluter Co., 112 E Centerway, Janesville, WI 53545, or equiv.).

(b) *Drill*.—Dremel Moto-Tool, Model 270 (30,000 rpm) with steel cutter No. 178 (Dremel Mfg. Co., 4915–21st St, Racine, WI 53406). Any drill with comparable speed may be used, but cutter must deflect removed shell outwards.

(c) *Forceps*.—Dissecting, medium-fine point, curved, 115 mm long (No. 079-392, Curtin Matheson Scientific Co., or equiv.).

(d) *Syringe*.—Microburet syringe, equipped to deliver 1–100  $\mu$ L (Micro-Metric Instrument Co., PO Box 22226, Cleveland, OH 44122, or equiv.).

(e) *Needles*.—B-D Yale, 1–1.5" long, 22 to 27 gage (Becton, Dickinson, and Co., or equiv.).

(f) *Sealing tape*.—Adhesive-cellophane tape, 1/2" wide. Scotch brand, or equiv.

(g) *Incubator/hatcher*.—Forced-draft, controlled temp. and humidity, with automatic turning (Humidaire Hatchette, 450 egg capacity; Humidaire Incubator Co., 217 W Wayne St, New Madison, OH 45346, or equiv.).

#### 26.085

#### Reagents

(a) *Aflatoxin B<sub>1</sub> std soln*.—10  $\mu$ g/mL absolute alcohol. See 26.004–26.011.  $\epsilon$  in absolute alcohol is same as in MeOH.

(b) *Hypochlorite soln*.—5% com. soln of NaOCl.

#### 26.086

#### Egg Supply

Eggs, fertile, from inbred Single-Comb White Leghorn flock (or other strain suitable for research or bioassay). Min. specifications are: (1) Nest clean (not dipped); (2) candled by supplier

to eliminate misplaced and tremulous air cells, blood spots, hair-line cracks or other shell imperfections, and other abnormalities; (3) delivered in new cartons and filler flats; (4) Pullorum typhoid clean and *Mycoplasma gallisepticum* neg.; (5) av. wt  $\leq 26$  but  $\geq 23$  oz/dozen; (6)  $\leq 48$  hr laid; (7) stored at 60°F and 80% relative humidity prior to delivery; (8) fertility  $\geq 85\%$ ; (9) feed of supplying flock must not contain any antibiotics, arsenicals, or nitrofurazones, but must be fully fortified to produce strong healthy chicks. Samples of feed must be supplied upon request for check analyses.

#### 26.087

#### General Technic

Candle eggs and outline clearly with pencil location of air cell. Reject any eggs with imperfections such as those listed under 26.086(2).

Using random selection, divide eggs into groups of required number for each level of samples to be injected. Date and label each egg of all groups with identifying code. Use pencil with No. 3 hardness lead to avoid smearing of markings when handling.

In center of air cell of each egg, drill hole ca 5 mm diam. Remove visible *shell* membrane with forceps (see Fig. 26:03) so that no fragments remain to interfere with introduction of needle.

Using syringe, and needle bent to form 90° angle (see Fig. 26:03), dispense required amt of sample onto *egg membrane*, being careful not to penetrate membrane. Immediately seal hole with piece of cellophane-adhesive tape large enough to cover hole, but covering as little as possible of remaining air cell. Let eggs remain undisturbed in vertical position (air cell up) ca 1 hr to let material disperse.

Place eggs in incubator trays and load incubator set to maintain temp. and relative humidity (rh) recommended by manufacturer. Optima are 37.4° (99.75°F) and 60% rh. Fumigate incubator immediately after loading, using fumigant and technics recommended by manufacturer of incubator. If automatic

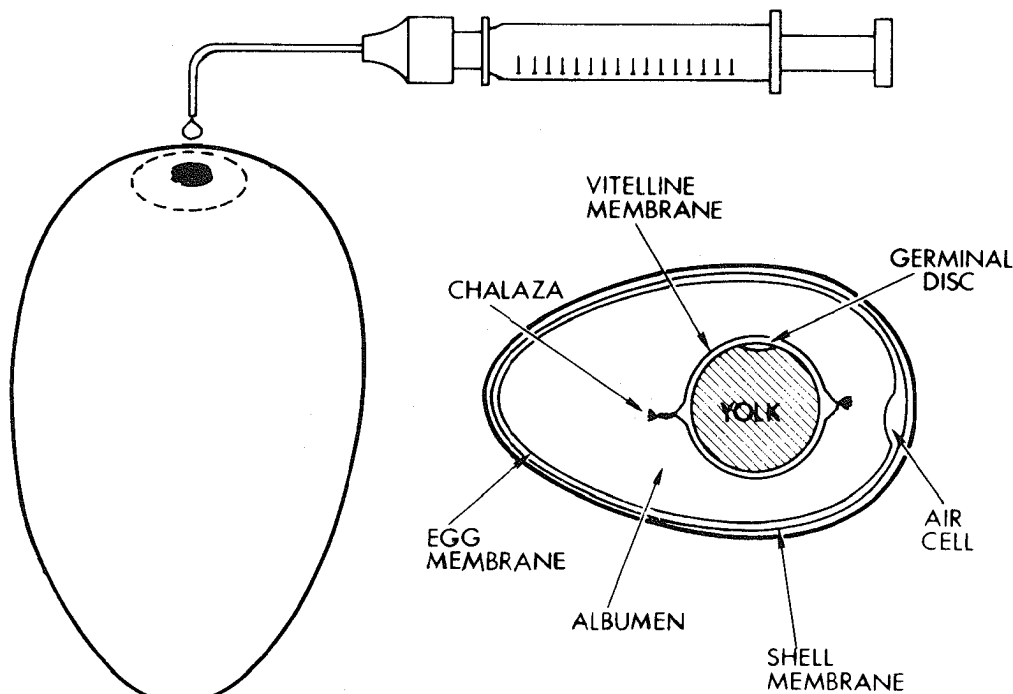

FIG. 26:03—Schematic showing parts of egg and modes of test material introduction

turning is provided, set for turning every 2 hr; if no automatic turning is provided, turn by hand at least twice daily thru 17th day of incubation.

Candle eggs on fourth day, and daily thereafter. Remove clear eggs and dead embryos for opening and examination. Keep record of age at death and appearance of all embryos for all test solns and controls thruout incubation period. On 17th day, place eggs in hatching tray (no further turning necessary), place in hatcher, set at recommended temp. and rh, and fumigate. Let eggs continue hatching and remove after all have hatched and dried (22nd or 23rd day).

Open and examine all unhatched eggs, examine chicks that hatch, and record observations.

**26.088****Standard Aflatoxin B<sub>1</sub> Dose Response**

Using aflatoxin B<sub>1</sub> std soln, det. dose response for egg supply under experimental conditions that will prevail in future assays:

Using  $\geq 100$  eggs/dose level, treat eggs as in **26.087**, at  $\geq 5$  dose levels ranging from no effect to 100% mortality. (Altho this may be done as single experiment, it is preferable to do it over period of time, e.g., 25 eggs/level repeated 4 times, or any combination until total of  $\geq 100$  eggs/level has been reached.)

Construct dose-response curve ( $\mu\text{g}$ -log % mortality), using method of Litchfield and Wilcoxon, *J. Pharmacol. Exp. Therap.* **96**, 99-113(1949). Per cent mortality for each treatment is total of nonviable embryos and unhatched chicks divided by total eggs treated. (Precise LD<sub>50</sub> and slope may vary depending upon sensitivity of embryos and environmental factors, but no-effect level to 100% mortality may be expected to fall between 0.01 and 0.20  $\mu\text{g}$ /egg; see JAOAC **47**, 1003(1964).)

**26.089****Assay**

(a) *Complete protocol*.—For initial assay of system or when new std, new supply of solv., or eggs from new flock are employed. Include  $\geq 30$  noninjected controls in all assays to check fertility and hatchability of eggs used, and to monitor incubation conditions.

Prep. ext as in **26.077–26.079**. Dissolve material to be assayed in absolute alcohol to obtain final aflatoxin B<sub>1</sub> concn of 10  $\mu\text{L}$ /mL (test soln), based on chem. analysis. Set up protocol, based on dose response obtained in **26.088**, according to Table **26:05**.

(b) *Routine protocol*.—After complete protocol is performed several times to assure system is functioning properly, levels of std and solv. indicated by <sup>b</sup> in Table **26:05** may be omitted. Complete protocol must be performed when there is any change in experimental conditions.

(c) *Lower level protocol*.—If insufficient material is available for complete protocol, reduce number of eggs per level and number of levels. Use min. of 2 levels: highest level, to assure

**Table 26:05 Complete protocol**

No. of Eggs	Quantity Injected <sup>a</sup>		Expected Mortality, %	Material Injected
	mL	$\mu\text{g}$		
$\geq 20$	0.020	0.20	100	Test soln
$\geq 20$	0.010	0.10	100	Test soln
$\geq 20$	0.005	0.05	90	Test soln
$\geq 20$	0.0025	0.025	50	Test soln
$\geq 20$	0.020	0.20	100	B <sub>1</sub> std soln, 10 $\mu\text{g}$ /mL

<sup>a</sup> Figures given are examples, based on JAOAC **47**, 1003(1964).

<sup>b</sup> See **26.089(b)**.

some toxic response even if chem. analysis is higher than true value, and 1 of 2 lowest levels. Besides mortality, presence of aflatoxin B<sub>1</sub> is also demonstrated by teratogenic effects occurring in Single Comb White Leghorn embryo after 12 days, severe growth retardation (e.g., 21-day embryo may be as small as normal 12-day embryo), short feet, edema, and hemorrhaging.

**AFLATOXIN M<sub>1</sub>**

(Aflatoxin M<sub>1</sub> is hydroxylated metabolite of aflatoxin B<sub>1</sub>, secreted in milk of mammals receiving aflatoxin B<sub>1</sub>. It is potential hepatocarcinogen. Handle with same care as other aflatoxins.)

**Aflatoxin M<sub>1</sub> in Dairy Products (17)—Official Final Action**

(Caution: See **51.011**, **51.039**, **51.040**, **51.045**, **51.046**, **51.054**, **51.056**, and **51.061**.)

**26.090****Apparatus**

(a) *Explosion-proof blender*.—Waring Model EP-1, or equiv., with 1 L jar and cover.

(b) *Chromatographic tubes*.—500  $\times$  22 (id) mm, with Teflon stopcock and glass tip (Kimble 17800 or Corning 2145).

(c) *Densitometer*.—See **26.001(e)**.

**26.091****Reagents**

(a) *Solvents*.—Distd-in-glass acetone, benzene, CHCl<sub>3</sub>, ether (0.01% EtOH), hexane (bp 68–69°), MeOH, and isopropanol.

(b) *Lead acetate soln*.—See **26.053(b)**.

(c) *Sodium sulfate soln*.—Satd. Dissolve  $\geq 150$  g anhyd. Na<sub>2</sub>SO<sub>4</sub> in 500 mL H<sub>2</sub>O at room temp. Prep. 2–3 days before use to ensure satn.

(d) *Diatomaceous earth*.—Hyflo Super-Cel.

(e) *Cellulose*.—Whatman CF-11 or CF-1 cellulose powder for column chromatgy. Soak ca 4 hr in hot CHCl<sub>3</sub>, filter, wash with CHCl<sub>3</sub>, and air dry. Check each lot for M<sub>1</sub> recovery by adding 1  $\mu\text{g}$  to neg. milk ext and treating as in **26.093–26.094**.

(f) *Aflatoxin M<sub>1</sub> std solns*.—Approx. 0.50  $\mu\text{g}$ /mL for visual analysis and 0.10  $\mu\text{g}$ /mL for densitometric analysis. See **26.004–26.011**.

**26.092****Preliminary Purification**

Weigh or measure fluid or powd milk or butter into blender jar and add H<sub>2</sub>O as indicated in Table **26:06**. Add ca 10 g diat. earth and 300 mL acetone, and blend 3 min. With cheese, cut into small cubes and add individually to mixt. of acetone, H<sub>2</sub>O, and diat. earth. Filter thru folded 32 cm Whatman No. 2V paper, or equiv., into 500 mL graduate.

Transfer 275 mL filtrate to 600 mL beaker contg 20 mL Pb(OAc)<sub>2</sub> soln. Rinse graduate with 200 mL H<sub>2</sub>O and add rinse to beaker. Stir and let stand ca 5 min for pptn. Add 10 mL satd Na<sub>2</sub>SO<sub>4</sub> soln and 10 g diat. earth, stir, and filter thru paper into same 500 mL graduate used above.

Transfer 350 mL filtrate to 500 mL separator, add 100 mL hexane (with annato-colored cheese or butter use ether), and shake vigorously ca 1 min. Let phases sep., and drain lower aq. phase into clean 600 mL beaker. Discard upper ether phase and pour aq. phase back into same separator. Retain beaker for CHCl<sub>3</sub> ext. Rinse beaker with 50 mL 5% NaCl soln, transfer rinse to separator, and add 100 mL CHCl<sub>3</sub>. Shake funnel ca 1 min and let phases sep. 2–3 min. Drain lower CHCl<sub>3</sub> layer into the 600 mL beaker and re-ext aq. mixt. with addnl 50 mL CHCl<sub>3</sub>. Combine CHCl<sub>3</sub> exts; discard aq. layer, and transfer combined CHCl<sub>3</sub> ext back to separator. Rinse beaker with 100 mL 5% NaCl soln, transfer rinse to separator, and wash CHCl<sub>3</sub> ext by vigorously shaking 1 min. Drain lower (CHCl<sub>3</sub>) phase thru ca 5 cm anhyd.

granular  $\text{Na}_2\text{SO}_4$  in Butt tube or ca 45 g in folded Whatman No. 2V paper into clean 400 mL beaker. Discard aq. phase. Rinse 600 mL beaker twice with  $\text{CHCl}_3$  and filter rinse thru the  $\text{Na}_2\text{SO}_4$ . Evap.  $\text{CHCl}_3$  on steam bath under gentle stream of N; do not overheat dry ext (vac. evapn may be used).

**26.093****Column Chromatography**

Place small glass wool pad in bottom of chromatgc tube, and tamp firmly. Slurry 10 g cellulose powder in ca 70 mL  $\text{MeOH-H}_2\text{O}$  (7+3), pour into column, and wash walls with the aq.  $\text{MeOH}$ . Drain solv. to top of cellulose, add ca 100 mL hexane, and let ca 50 mL drain thru column. Place small glass wool pad on top of cellulose, and tamp firmly to pack cellulose and prevent channeling. Drain remaining hexane to top of glass wool pad.

Dissolve dry ext, **26.092**, in 1 mL  $\text{CHCl}_3$ , and add 2 mL benzene and 10 mL hexane. Transfer to prepd column, wash sample beaker with ca 5 mL hexane-benzene (3+1), and add wash to column. When sample soln reaches top of glass wool pad, wash column with 150 mL hexane-benzene (3+1) and then 150 mL hexane-ether (2+1), letting first soln drain to top of glass wool pad before adding second. Discard column washes. Elute aflatoxin  $\text{M}_1$  ( $\text{B}_1$  also, if present) with 200 mL hexane- $\text{CHCl}_3$  (1+1), and collect eluate in clean 250 mL beaker. Evap. solv. to near dryness on steam bath (vac. evapn may be used), transfer quant. with  $\text{CHCl}_3$  to small vial (ca 1–2 drams), **26.001(m)**, and evap. to dryness on steam bath under stream of N.

**26.094****Thin Layer Chromatography**

Add 100  $\mu\text{L}$   $\text{CHCl}_3$  to dry sample residue in vial, cap, and shake vigorously ca 1 min, preferably on Vortex shaker. Sample vol. is sufficient for *either* visual or densitometric analysis, but not both.

**a) Visual analysis.**—Proceed as in **26.031(a)**, (**b**) (except spot two 20  $\mu\text{L}$  sample spots and 2, 4, 6, 8, and 10  $\mu\text{L}$   $\text{M}_1$  std, 0.5  $\mu\text{g}/\text{mL}$ ; spot 4  $\mu\text{L}$   $\text{M}_1$  std on top of one sample spot as internal std; and develop ca 12 cm (ca 50 min) with isopropanol-acetone- $\text{CHCl}_3$  (5+10+85)), and **26.031(d)**, where  $W$  = vol. or wt milk product represented by final ext for TLC, Table **26.06**.

**(b) Densitometric analysis.**—Spot three 20  $\mu\text{L}$  sample spots and two 20  $\mu\text{L}$   $\text{M}_1$  std spots, 0.1  $\mu\text{g}/\text{mL}$ . Spot third 20  $\mu\text{L}$  std spot on top of one 20  $\mu\text{L}$  sample spot as internal std. Develop plate as in (**a**). Examine plate under longwave UV light to confirm presence or absence of  $\text{M}_1$  in sample. If  $\text{M}_1$  is present, scan plate as in **26.059(c)**.  $W$  = vol. or wt milk product represented by final ext for TLC, Table **26.06**.

**Table 26.06 Data for Preparation of Sample of Milk Products**

Milk Product	Sample Vol. or Wt	$\text{H}_2\text{O}$ Added Before Ext <sup>a</sup> , mL	Sample Equiv. in Final Ext <sup>b</sup>
Fluid milk	100 mL	10	47.6 mL
Powdered milk	10 g	100	4.8 g
Blue cheese	50 g	80	23.8 g
Ricotta cheese	50 g	65	23.8 g
Cheddar cheese	50 g	80	23.8 g
Butter	50 g	90	23.8 g

<sup>a</sup>  $\text{H}_2\text{O}$  calcd to provide const vol. of 100 mL per sample; mL  $\text{H}_2\text{O}$  added =  $[100 - (W' \times M/100)]$ , where  $W'$  = wt or vol. sample extd and  $M$  = %  $\text{H}_2\text{O}$  from values obtained from USDA Handbook No. 8, 1963.

<sup>b</sup> Values represent sample wt,  $W$ , in calcs, based on aliquot factors used in method,  $(275/400) \times (350/505) \times$  sample size.

**26.095 Confirmation of Aflatoxin  $\text{M}_1$  Identity by Derivative Formation and TLC (77)—Official First Action**

Place ca 30 ng aflatoxin  $\text{M}_1$ , obtained by either preparative TLC, **26.079**, or by column chromatgy, **26.093**, and 30 ng  $\text{M}_1$  std

in 1 dram vials with Teflon liners, and evap. to dryness under slow stream of N. Add 100  $\mu\text{L}$  freshly prepd pyridine- $\text{Ac}_2\text{O}$  (1+1), cap vial, and mix vigorously. Let stand 15 min at room temp. Evap. to dryness on steam bath under N. Dissolve in 60  $\mu\text{L}$   $\text{CHCl}_3$  by mixing vigorously.

Spot 20  $\mu\text{L}$  acetate derivative from sample and from std and 1–2 ng aflatoxin  $\text{M}_1$  on TLC plate. Reserve remainder for hemiacetal formation. Develop plate ca 1 hr at 25° with acetone- $\text{CHCl}_3$  (1+9) in unlined, unequilibrated tank. Examine plate under longwave UV light (365 nm). Aflatoxin  $\text{M}_1$  appears at  $R_f$  = ca 0.11 and the acetate at ca 0.55.

Evap. reserved soln under N. Add 100  $\mu\text{L}$   $\text{H}_2\text{O}$  and 1–2 drops  $\text{HCl}$ . Cap vial, shake vigorously, heat 10 min on steam bath, and evap. to dryness on steam bath under N. Dissolve residue in 40  $\mu\text{L}$   $\text{CHCl}_3$ . Spot 20  $\mu\text{L}$  sample hemiacetal derivative, 20  $\mu\text{L}$  std derivative prepd similarly, and 1–2 ng aflatoxin  $\text{M}_1$ . Develop plate in isopropanol-acetone- $\text{CHCl}_3$  (1+1+8) and examine for hemiacetal derivative. Aflatoxin  $\text{M}_1$  appears at  $R_f$  = ca 0.70 and the hemiacetal at ca 0.15.

**OCHRATOXINS**

(Ochratoxin A causes kidney and liver damage in some animals. Observe precautions given in introductory statement of this chapter.)

**Barley (18)—Official First Action**

(Quant. for ochratoxin A, qual. for B and for esters of A and B. Caution: See **51.011**, **51.016**, **51.045**, **51.056**, and **51.061**.)

**26.096****Principle**

Ochratoxin acids and esters are extd from barley by  $\text{CHCl}_3$ -aq.  $\text{H}_3\text{PO}_4$ . Acids are entrapped on aq.  $\text{NaHCO}_3$ -diat. earth column, esters and fat are removed with hexane and  $\text{CHCl}_3$ , and acids are eluted with  $\text{HCOOH-CHCl}_3$ . Esters are isolated by entrapment on  $\text{MeOH-aq. NaHCO}_3$ -diat. earth column, fats are removed with hexane-benzene, and esters are eluted with  $\text{HCOOH-hexane-benzene}$ . Compds are detd from fluorescence intensity on thin layer chromatograms.

All glassware must be free of alk. soap or detergent residues to avoid loss of the toxins from neut. solv. by salt formation, pptn, and/or adsorption onto glassware.

**26.097****Apparatus**

**(a) Chromatographic tubes.**—700  $\times$  17 (od) mm and 350  $\times$  25 mm, with stopcocks.

**(b) Buchner funnels.**—Glass, 9 cm diam. fitted with Whatman GF/B glass fiber paper, or equiv.; 24 cm diam. fitted with Whatman No. 1 paper, or equiv.

**(c) Thin layer chromatographic apparatus.**—See **26.001(k)**.

**(d) Densitometer.**—See **26.001(e)**.

**26.098****Reagents**

See **26.002(b)**, plus the following:

**(a) Diatomaceous earth.**—Soak ca 900 g acid-washed Celite 545 overnight in  $\text{MeOH}$ . Filter thru double thickness Whatman No. 1 paper in 24 cm buchner, wash with 8 L  $\text{H}_2\text{O}$ , and dry 12 hr at 150°.

**(b) Silica gel for thin layer chromatography.**—See **26.002(d)**. Test adsorbent for resolution and fading of ochratoxins as in **26.002(d)**, using ochratoxins A and B and their Et esters as in **26.102**. Develop with benzene- $\text{MeOH-HOAc}$ , (**h**)(1). TLC spots should be round or slightly elliptical, well sepd, in  $R_f$  range 0.4–0.9, and located away from primary and secondary solv. fronts. Ochratoxins on occasion fade rapidly on some silica gel

plates, especially when exposed to  $\geq 60\%$  humidity. Protect plate from humidity during spotting by placing in chamber under N or under stream of warm air from hair dryer, or by covering with clean glass plate, using tape on sides as spacers. After development, dry plate 15 min at  $50^\circ$  and immediately cover with clean glass plate, using tape on sides as spacers, for protection during scanning densitometry.

(c) *Solvents*.—ACS, in glass:  $\text{CHCl}_3$ , hexane, HOAc, MeOH, HCOOH (90%), and  $\text{H}_3\text{PO}_4$  (85%).

(d) *Methanolic sodium bicarbonate soln.*—Dissolve 0.3 g  $\text{NaHCO}_3$  in 30 mL  $\text{H}_2\text{O}$  and add 70 mL MeOH.

(e) *Alcoholic sodium bicarbonate soln.*—Dissolve 6.0 g  $\text{NaHCO}_3$  in 100 mL  $\text{H}_2\text{O}$  and add 20 mL alcohol.

(f) *Formic acid-benzene-hexane soln.*—Shake 100 mL benzene-hexane (20+80) with 10 mL  $\text{H}_2\text{O}$ -MeOH (30+70), let layers sep., and discard lower layer. Shake upper layer with 5 mL HCOOH, let sep., and discard lower layer.

(g) *Boron trifluoride*.—14% (w/w). Bubble gaseous  $\text{BF}_3$  into chilled alcohol. (Caution: Perform in hood. Avoid contact with skin, eyes, and respiratory tract.)

(h) *Developing solvents*.—(1) *Benzene-methanol-acetic acid (18+1+1)*.—Combine 2 vols MeOH-HOAc (1+1) with 18 vols benzene. Adjust benzene:(MeOH-HOAc) ratio, if necessary, to produce development described in 26.102. Decrease benzene to increase  $R_f$ . (2) *Hexane-acetone-acetic acid (18+2+1)*.—Combine 3 vols acetone-HOAc (2+1) with 18 vols hexane. Adjust hexane:(acetone-HOAc) ratio, if necessary, to produce development described in 26.102. Decrease hexane to increase  $R_f$ .

(i) *Ochratoxin std solns.*—See 26.004–26.011. Prep. original solns, each ca 40  $\mu\text{g/mL}$ , in HOAc-benzene (1+99). Det. concn as in 26.004–26.010, using following information:

Ochratoxin	$\lambda$ max., nm	MW	$\epsilon$
A	333	403	5550
B	320	369	6000
A Et ester	333	431	6200
B Et ester	320	397	6500

Combine portions of ochratoxin solns and dil. with benzene to give concn in range 1–5  $\mu\text{g/mL}$  for each ochratoxin.

(j) *Purified cotton*.—Wash 50 g absorbent cotton in beaker with 1 L  $\text{CHCl}_3$ . Decant soln., evap. residual  $\text{CHCl}_3$ , and store cotton in closed container.

## 26.099 Preparation and Extraction of Sample

Prep. entire sample as in 26.003.

Weigh 50 g into 500 mL g-s erlenmeyer. Add 25 mL 0.1M  $\text{H}_3\text{PO}_4$  and 250 mL  $\text{CHCl}_3$ , and secure stopper with masking tape. Shake 30 min on wrist-action shaker, 26.001(o), and filter thru glass fiber paper, covered with ca 10 g diat. earth, on 9 cm buchner.

## 26.100 Separation of Ochratoxin Acids

(a) *Removal of esters*.—Place plug of purified cotton, (j), in bottom of 700  $\times$  17 mm chromatgc tube. Mix 2.0 g diat. earth with 1 mL 1.25%  $\text{NaHCO}_3$  soln in 50 mL beaker. Add to chromatgc tube and tamp firmly. Mix 50 mL sample ext with 40 mL hexane, and add to column. Reserve remainder of  $\text{CHCl}_3$  sample ext for confirmation of identity, 26.103. Elute at max. flow rate; then elute with 75 mL  $\text{CHCl}_3$ . Combine eluates, evap. to dryness on steam bath, and reserve for ochratoxin ester sepn, 26.101.

(b) *Removal of acids*.—Elute ochratoxins A and B with 75 mL freshly prepd HCOOH- $\text{CHCl}_3$  (1+99), and collect in 250 mL erlen-

meyer. Immediately add 2 boiling chips, 26.002(b), evap. nearly to dryness on steam bath, and quant. transfer residue to 15 mL conical centrf. tube with  $\text{CHCl}_3$ . Evap. to dryness under gentle stream of N on steam bath. (Note: Delay in evapn of HCOOH- $\text{CHCl}_3$  may result in loss of ochratoxins.) Reserve ext for TLC, 26.102.

## 26.101

### Separation of Ochratoxin Esters

Prep. column as in 26.100(a), using 350  $\times$  25 mm chromatgc tube, 2.5 mL methanolic  $\text{NaHCO}_3$  soln, (d), and 4 g diat. earth. Dissolve residue, 26.100(a), in 50 mL hexane and add to column. Rinse extn vessel with each subsequent solv. in turn; add rinses to column. Force eluting solvs thru column at convenient rate with compressed gas at 1–2 psi (6.9–13.8 kPa). Do not let liq. fall below top of column. Elute with 50 mL benzene-hexane (1+9) previously equilibrated with 2.5 mL methanolic  $\text{NaHCO}_3$  soln (discard). Then elute with 100 mL HCOOH-benzene-hexane mixt. Immediately evap. eluate to dryness, quant. transfer to conical centrf. tube with  $\text{CHCl}_3$ , evap. to dryness under gentle stream of N on steam bath, and reserve for TLC, 26.102.

## 26.102

### Thin Layer Chromatography

(a) *Visual analysis*.—Proceed as in 26.031, with following modifications: Use silica gel, 26.098(b), and dissolve ext from 26.100(b) in 750  $\mu\text{L}$  HOAc-benzene (1+99). Spot 3, 5, 7.5, and 10  $\mu\text{L}$ . On same plate, spot 10  $\mu\text{L}$  ext superimposed with 10 ng each ochratoxin A and B std solns as internal std. Also spot 5, 7.5, and 10  $\mu\text{L}$  ochratoxin A and B std solns. Develop plate to solv. stop line, but <90 min, with benzene-MeOH-HOAc (18+1+1) in unlined, unequilibrated tank. Remove plate, let solv. evap. at room temp., and view in dark under long- and shortwave UV lamps. Ochratoxins A and B should be found in  $R_f$  range 0.4–0.8 with ochratoxin A above B, typically at 0.65 and 0.5, resp. Ochratoxin A fluoresces most intensely under longwave UV light, while ochratoxin B is brightest under shortwave light. Examine pattern from sample for fluorescent spots having  $R_f$  values close to those of stds and with similar appearance. Compare fluorescence intensities of ochratoxin A spots in sample with those of std spots, and det. std and sample which match most closely, interpolating, if necessary. If sample concn is outside range of stds, conc. or dil. sample ext and rechromatograph. Calc. concn of ochratoxin A in  $\mu\text{g/kg}$ . Spray plate with alc.  $\text{NaHCO}_3$  soln, (e), dry at room temp., and view in dark under longwave UV light. Fluorescence should have changed from greenish blue to blue and increased in intensity. Again est. ochratoxin A in sample. In case of disagreement, use est. obtained before spraying.

Proceed with TLC of ochratoxin A and B esters from 26.101 on sep. plate in same manner as above for acids, and develop plate with hexane-acetone-HOAc (18+2+1).  $R_f$  value of ochratoxin A ester is ca 0.5, above ochratoxin B ester.

(b) *Densitometric analysis*.—Prep. and develop TLC plate as in 26.098(b) and 26.102(a). In sep. channels, spot  $\geq 4$  spots with increasing amts std ochratoxin A in range 3–10 ng/spot. Scan TLC plate with densitometer according to instructions of manufacturer. Optimum spectral settings for ochratoxin A are excitation 310–340 nm; emission, 440–475.

Plot std curve from instrument response, drawing line thru origin to check for linearity and system performance. Dissolve sample ext in 0.5 mL HOAc-benzene (1+99) and spot  $\geq 2$  replicates of  $\geq 3 \mu\text{L}$  sample ext and std solns. Amt sample spotted must contain amt ochratoxin close to or within range of std curve.

### 26.103 *Confirmation of Identity of Ochratoxins A and B by Formation of Ethyl Esters*

Purify reserved  $\text{CHCl}_3$  ext as in 26.100(a) and (b). Dissolve portion of ext, 26.100(b), contg equiv. of  $\geq 10$  g sample, in 5 mL  $\text{CHCl}_3$  in 25 mL erlenmeyer. Into sep. 25 mL erlenmeyer, add 250 ng ochratoxin A and B std soln. (This step may be omitted when ester stds are available.) Add 10 mL 14%  $\text{BF}_3$  in alcohol. Heat to bp and hold on steam bath 5 min. Transfer to 125 mL separator contg 30 mL  $\text{H}_2\text{O}$ . Ext with three 10 mL portions  $\text{CHCl}_3$ . Combine  $\text{CHCl}_3$  exts, wash with three 10 mL portions  $\text{H}_2\text{O}$ , evap. to dryness, quant. transfer to 15 mL centr. tube with  $\text{CHCl}_3$ , and evap. to dryness under gentle stream of N. Dissolve residue in 250  $\mu\text{L}$  HOAc-benzene (1+99) and proceed as in 26.102(a), modified as follows:

Spot 10  $\mu\text{L}$  unmodified ext, 10  $\mu\text{L}$  esterified sample ext, 10  $\mu\text{L}$  std ochratoxin esters, and 10  $\mu\text{L}$  esterified sample ext plus 10  $\mu\text{L}$  std ochratoxin esters. Develop plate with benzene-MeOH-HOAc, 26.098(h)(1). Examine plate under long- and shortwave UV light.  $R_f$  of ochratoxin A ester is greater than that of ochratoxin B ester, typically 0.8 and 0.7, resp. Et esters have much higher  $R_f$  values than ochratoxins A and B, but approx. same fluorescence. For pos. confirmation, presumptive ochratoxin A or B spots should be absent after esterification and spots at  $R_f$  values of esters should be present.

Photograph TLC plate as in 26.082, using long- and shortwave UV light, f/8, and 5 sec exposure.

### Green Coffee (19)—Official First Action

#### 26.104 *Principle*

Toxin is extd from ground, green coffee beans with  $\text{CHCl}_3$ . Ochratoxin A is entrapped on basic diat. earth, interferences are removed with hexane and  $\text{CHCl}_3$ , and ochratoxin A is eluted with benzene-HOAc. Ochratoxin A is detd from fluorescent intensity on thin layer chromatograms.

Observe precautions of 26.096.

#### 26.105 *Apparatus*

- (a) *Chromatographic tubes*.—See 26.001(d).
- (b) *Thin layer chromatographic apparatus*.—See 26.001(k).
- (c) *Vials*.—See 26.001(m).
- (d) *Buchner funnel*.—Glass, 90 mm, fitted with Reeve Angel glass fiber filter paper, or equiv.

#### 26.106 *Reagents*

- (a) *Solvents*.—ACS grade in glass: HOAc, benzene,  $\text{CHCl}_3$ , MeOH.
- (b) *Alcoholic sodium bicarbonate soln*.—See 26.098(e).
- (c) *Bicarbonate-diatomaceous earth mixture*.—Add 25 mL 5% aq.  $\text{NaHCO}_3$  soln to 50 g acid-washed diat. earth, 26.098(a), and mix well. Can be stored 2–3 weeks in tightly closed container.
- (d) *Ochratoxin A std soln*.—1  $\mu\text{g}/\text{mL}$ . See 26.098(i).
- (e) *Silica gel for thin layer chromatography*.—See 26.098(b).

#### 26.107 *Preparation and Extraction of Sample*

Prep. entire sample as in 26.003.

Weigh 25 g sample into 500 mL g-s erlenmeyer. Add 12.5 mL  $\text{H}_2\text{O}$ , mix to wet sample, and add 125 mL  $\text{CHCl}_3$ . Shake 30 min on mech. shaker, 26.001(o), and filter thru 18.5 cm glass fiber paper in powder funnel or thru 9 cm glass fiber paper, using buchner.

### 26.108 *Column Chromatography*

Place glass wool plug in bottom of chromatgc tube. Weigh 6 g  $\text{NaHCO}_3$ -diat. earth mixt., transfer to tube, and tamp firmly. Add 50 mL  $\text{CHCl}_3$  ext to column, and elute until meniscus reaches top of column. Wash with 70 mL hexane followed by 70 mL  $\text{CHCl}_3$ , discarding washings. Elute with 100 mL HOAc-benzene (2+98), collecting eluate in 125 mL erlenmeyer. Evap. to near dryness on steam bath under N, and transfer quant. with  $\text{CHCl}_3$  to 4 dram vial. Evap. under N, and add 500  $\mu\text{L}$  HOAc-benzene (1+99). Shake vigorously to dissolve, preferably with Vortex shaker.

### 26.109 *Thin Layer Chromatography*

Proceed as in 26.102(a) except that toluene-EtOAc-formic acid (5+4+1) is preferred developing solv. Alternatively, use benzene-MeOH-HOAc (18+1+1), but 2 sequential developments with this solv. may be necessary to obtain adequate sepn from background.

### 26.110 *Confirmation*

Spray plate with alc.  $\text{NaHCO}_3$  soln or alc.  $\text{AlCl}_3$  soln (20 g  $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$  in 100 mL alcohol) or expose plate to  $\text{NH}_3$  vapor. Fluorescence of ochratoxin under longwave UV light changes to bright blue and increases in intensity.

See also 26.103.

### PATULIN

(Caution: Patulin is antibiotic with demonstrated mutagenicity and unknown toxicity to man. Handle with caution as possibly deleterious substance)

### Apple Juice (20)—Official First Action

#### 26.111 *Principle*

Apple juice is extd with EtOAc and ext is cleaned up on silica gel column. Patulin is detected in eluate, after concn, by TLC, by spraying with 3-methyl-2-benzothiazolinone hydrazone.HCl soln. Limit of determination is ca 20  $\mu\text{g}/\text{L}$ .

#### 26.112 *Apparatus*

See 26.001(d), (g), (i), (l), and (m) plus following:

- (a) *Beakers*.—Glass, 250 mL with 25 mL graduations.
- (b) *Thin layer chromatographic apparatus*.—See 26.001(k), plus the following: spray bottle, 125 mL flask, to produce fine, even spray (Kontes Glass Co., No. K-422500); sample streaker for preparative TLC (Applied Science Laboratories, Inc., No. 17700, or equiv.).
- (c) *Analytical microbalance*.—See 26.004(b).

#### 26.113 *Reagents*

- (a) *Solvents*.—Benzene, EtOAc; redistil and discard forerun.
- (b) *Sodium sulfate*.—See 26.002(e).
- (c) *Silica gel*.—(1) For column chromatography.—E. Merck silica gel 60, 0.063–0.2 mm, 26.027(a). (2) For thin layer chromatography.—Adsorbosil-5, 26.002(d); E. Merck silica gel G precoated Uniplat (Analtech, Inc., 75 Blue Hen Dr, Newark, DE 19711); or equiv.
- (d) *Patulin std soln*.—(1) From crystals.—Weigh ca 0.5 mg pure cryst. patulin (available from Makor Chemicals Ltd., POB 6570, Jerusalem, Israel) to nearest 0.001 mg and dissolve in  $\text{CHCl}_3$  to 10  $\mu\text{g}/\text{mL}$ . (2) From stock soln in  $\text{CHCl}_3$ .—Withdraw vol., using precision syringe, and dil. with  $\text{CHCl}_3$  to prep. concn of 10  $\mu\text{g}/\text{mL}$ .

Using precision syringe, withdraw 5.0 mL std soln (10  $\mu\text{g/mL}$ ) into 4 dram vial and evap. to dryness under N. Immediately add 5.0 mL absolute alcohol. Record UV spectrum of patulin soln from 350 to 250 nm against absolute alcohol in ref. cell. Det. concn of patulin soln from  $A$  at wavelength of max. absorption, ca 275 nm, using following equation (1 cm cell pathlength):  $\mu\text{g patulin/mL} = (A \times MW \times 1000 \times CF)/\epsilon$ , where  $CF$  = correction factor obtained in **26.004(a)**,  $MW = 154$ , and  $\epsilon = 14,600$ .

Store std and stock solns at  $0^\circ$  in g-s vol. flasks, wrapped tightly in Al foil. Bring std to room temp. before use; do not remove Al foil from flask until contents have reached room temp. Do not store std as thin film from evapd soln because of decomposition of patulin.

(e) *3-Methyl-2-benzothiazolinone hydrazone (MBTH) hydrochloride soln.*—Dissolve 0.5 g MBTH.HCl.H<sub>2</sub>O (Aldrich Chemical Co., Inc., No. 12,973-9) in 100 mL H<sub>2</sub>O. Store in refrigerator and prep. fresh every 3 days.

## 26.114

### Extraction

Analyze sample immediately after opening can or bottle. Vigorously ext 50 mL sample with three 50 mL portions EtOAc in 250 mL separator. Dry combined exts (upper phase) ca 30 min over 20 g anhyd. Na<sub>2</sub>SO<sub>4</sub>; break up initially formed lumps with glass rod. Decant into graduated 250 mL beaker. Wash Na<sub>2</sub>SO<sub>4</sub> with two 25 mL portions EtOAc and add to ext. Evap. to <25 mL (*Caution*: Do not evap. to dryness) on steam bath under gentle stream of N. Let cool to room temp., adjust vol. to 25 mL mark, if necessary, with EtOAc, and dil. to 100 mL with benzene.

## 26.115

### Column Chromatography

Place glass wool plug firmly in bottom of chromatgc tube contg ca 10 mL benzene and add slurry of 15 g silica gel in benzene. Wash sides of tube with benzene, let silica gel settle, and drain solv. to top of adsorbent. Carefully add sample ext to column, drain to top of silica gel, and discard eluate. Elute patulin with 200 mL benzene-EtOAc (75+25) at ca 10 mL/min. Evap. eluate to near dryness under N on steam bath.

Quant. transfer residue to 4 dram vial with CHCl<sub>3</sub> and evap. to dryness under N on steam bath. Immediately dissolve residue in 500  $\mu\text{L}$  CHCl<sub>3</sub> with aid of Vortex mixer. Seal with polyethylene stopper. If TLC is not performed on same day, store soln in freezer to avoid evapn of solv.

## 26.116

### Thin Layer Chromatography

(a) *Preparation of plates.*—See **26.031(a)**.

(b) *Preliminary thin layer chromatography.*—Puncture polyethylene stopper to accommodate needle of 10  $\mu\text{L}$  syringe. Spot two 5  $\mu\text{L}$  spots and one 10  $\mu\text{L}$  spot of ext soln and 1, 3, 5, 7, and 10  $\mu\text{L}$  spots of std soln on imaginary line 4 cm from bottom edge of TLC plate. Spot 5  $\mu\text{L}$  std soln on top of one 5  $\mu\text{L}$  ext spot. Develop plate with toluene-EtOAc-90% formic acid (5+4+1) contained in V-shaped metal trough inside unlined but equilibrated tank, with silica gel layer facing max. tank vol. When solv. front reaches 4 cm from top of plate, remove plate from tank and dry in air, preferably in hood.

Spray plate with 0.5% MBTH soln until layer appears wet; then heat ca 15 min in  $130^\circ$  oven. Examine plate in transmitted and reflected longwave UV light. Patulin appears as yellow-brown fluorescent spot at  $R_f$  ca 0.5. One  $\mu\text{L}$  std soln (10  $\mu\text{g/mL}$ ) should be just detectable. Patulin may also be seen as yellow spot under visible light if  $\geq 0.05 \mu\text{g}$ .

Compare sample chromatogram patterns with that contg internal std. Fluorescent spot in sample thought to be patulin must have  $R_f$  value and color identical to patulin std spot when

unknown spot and internal std spot are superimposed. Spot from sample and internal std combined should be more intense than either sample or std alone. Visually compare fluorescence intensity of patulin spots in sample and std. To aid in detn, move plate away from lamp to attenuate UV light so that any particular pair of spots can be compared at extinction. If intensity of sample spot is between those of 2 std spots, interpolate or rechromatograph, spotting appropriate vols of sample and std soln to obtain closer est. If weakest sample spot is too intense to match stds, dil. sample ext and rechromatograph.

$$\mu\text{g Patulin/L} = (S \times Y \times V)/50 \times X,$$

where  $S = \mu\text{L}$  std equal to unknown,  $Y = \text{concn of std in } \mu\text{g/mL}$ ,  $V = \mu\text{L}$  of final diln of sample ext, and  $X = \mu\text{L}$  sample ext spotted giving fluorescent intensity equal to  $S$  (std).

Sprayed TLC plate will slowly turn blue on standing in air for few hr, unless covered by second glass plate.

(c) *Preparative thin layer chromatography.*—Streak ext on TLC plate. Spot patulin std and 10  $\mu\text{L}$  ext plus internal std at side of plate. Scribe line between std and sample area to prevent cross contamination of sample area. Develop plate as in (b). Dry in air. Cover most of plate with second glass plate and spray stds and streak ca 1 cm wide with 0.5% MBTH soln; then heat 15 min at  $130^\circ$ . Det. position of patulin under longwave UV light. Remove unsprayed patulin band with suction and filter device, **26.076(b)**. Elute patulin from silica gel with ca 10 mL CHCl<sub>3</sub>-acetone (2+1), using slight air or N pressure. Evap. eluate to dryness in 4 dram vial and immediately dissolve residue in 100  $\mu\text{L}$  CHCl<sub>3</sub>.

(d) *Confirmatory thin layer chromatography.*—Spot 10–20  $\mu\text{L}$  soln from (c) and 5  $\mu\text{L}$  patulin std for confirmatory TLC in each of following 3 solv. systems, using unlined, unequilibrated developing tank: hexane-anhyd. ether (1+3), CHCl<sub>3</sub>-MeOH (95+5), and CHCl<sub>3</sub>-acetone (90+10). Approx.  $R_f$  values of patulin are 0.4, 0.4, and 0.5, resp.

## STERIGMATOCYSTIN

(Sterigmatocystin is carcinogen. Observe precautions given in introductory statement of this chapter.)

### Barley and Wheat (21)—Official First Action

## 26.117

### Apparatus

(a) *Thin layer chromatographic apparatus.*—See **26.001(k)** and **26.076(b)**.

(b) *Chromatographic tubes.*—22  $\times$  300 mm, **26.001(d)**.

## 26.118

### Reagents

(a) *Solvents.*—ACS, in glass: CH<sub>3</sub>CN, hexane, benzene, alcohol, MeOH, HOAc, EtOAc, cyclohexane, acetone, pyridine, and Ac<sub>2</sub>O.

(b) *Potassium hydroxide soln.*—20%. Dissolve 20 g KOH pellets in 100 mL MeOH.

(c) *Aluminum chloride soln.*—20%. Dissolve 20 g AlCl<sub>3</sub>·6H<sub>2</sub>O in 100 mL alcohol.

(d) *Silica gel.*—(1) *For column chromatography.*—0.063–0.2 mm (E. Merck, thru Brinkmann Instruments, Inc., or equiv.). (2) *For thin layer chromatography.*—Adsorbosil-1 (Applied Science Laboratories, Inc.), or equiv.

(e) *Sterigmatocystin std solns.*—Det. chromatgc purity of cryst. sterigmatocystin as in **26.010**. (1) *Qualitative  $R_f$  reference std soln.*—Approx. 100  $\mu\text{g/mL}$  benzene. (2) *Quantitative reference std soln.*—Approx. 5  $\mu\text{g/mL}$  benzene. Prep. soln ca 10  $\mu\text{g/mL}$ , and det. concn as in **26.009**, using for sterigmatocystin: max.  $A$  325 nm,  $MW$  324,  $\epsilon$  15,200. Dil. quant. to ca 5  $\mu\text{g/mL}$ .

**26.119 Sample Preparation and Extraction**

(Caution: See 51.011, 51.039, 51.040, 51.043, 51.056, and 51.061.)

Grind total sample as in 26.003. Weigh 50 g finely ground sample into 500 mL g-s erlenmeyer, add 180 mL  $\text{CH}_3\text{CN}$  and 20 mL 4% KCl soln, and secure stopper with masking tape. Agitate 30 min on wrist-action, 26.001(o), or oscillating shaker, and decant thru Whatman No. 1, or equiv., fluted paper in 150 mm short-stem funnel. Transfer 100 mL filtrate to 250 mL separator, add 50 mL hexane, shake, and let layers sep. Discard upper (hexane) layer. Repeat with addnl 50 mL hexane and discard. Add 25 mL  $\text{H}_2\text{O}$  and 50 mL  $\text{CHCl}_3$  to  $\text{CH}_3\text{CN-H}_2\text{O}$  and shake. Collect clear lower layer in 250 mL erlenmeyer. Add 25 mL  $\text{CHCl}_3$  to  $\text{H}_2\text{O}$  layer and shake. Add clear lower layer to erlenmeyer. Add few SiC boiling chips, 26.002(b), evap. to incipient dryness in steam bath, and quant. transfer residue with  $\text{CHCl}_3$  thru filter paper into 4 dram vial, 26.001(m). Evap. to dryness on steam bath under gentle stream of N. Seal vial with hollow polyethylene stopper, 26.001(i), and cap. Reserve for TLC, 26.120.

**26.120 Preliminary Thin Layer Chromatography**

Prep. plates as in 26.031(a) and proceed as in 26.031(b), except use 1 mL benzene as solv. and spot 1  $\mu\text{L}$ , two 5  $\mu\text{L}$ , and one 10  $\mu\text{L}$  spots of sample. On same plate, spot 1, 2, 5, and 10  $\mu\text{L}$  quant. ref. std sterigmatocystin, 26.118(e)(2). Spot 5  $\mu\text{L}$  std on top of one 5  $\mu\text{L}$  sample spot.

Develop plate with benzene-HOAc-MeOH (90+5+5) in lined tank, equilibrated with same solv. When solv. front reaches line 4 cm from top of plate, remove plate from tank and dry. Spray plate evenly with  $\text{AlCl}_3$  soln. Heat plate 10 min at 80°. Examine under shortwave UV light for bright yellow fluorescent sterigmatocystin std spots. (Caution: See 51.016.) Examine sample pattern for similar yellow fluorescent spots at same  $R_f$ . If similar spots are not seen in sample channel, sample contains <100  $\mu\text{g}$  sterigmatocystin/kg. If yellow fluorescent spots are seen, compare fluorescent intensity of sample spots with those of std spots and det. which sample portion matches one of stds. Interpolate, if necessary. If weakest sample spot is stronger than most concd std spot, adjust sample ext vol. and rechromatograph.

$$\mu\text{g Sterigmatocystin/kg} = (S \times Y \times V) / 25 \times X,$$

where  $S$  =  $\mu\text{L}$  std equiv. to unknown,  $Y$  =  $\mu\text{g}$  std/mL,  $V$  =  $\mu\text{L}$  final sample ext diln, and  $X$  =  $\mu\text{L}$  sample ext spotted giving fluorescent intensity equal to std  $S$ .

If no fluorescent yellow spot is seen at proper  $R_f$  or there is too much interference for proper quantitation, proceed as in 26.121.

**26.121 Column Chromatography**

(Caution: See 51.011, 51.039, 51.051, and 51.057.)

Place glass wool plug loosely in bottom of chromatgc tube and add ca 5 g anhyd.  $\text{Na}_2\text{SO}_4$  to give even base for silica gel. Add cyclohexane until column is ca  $\frac{1}{2}$  full; add 10 g silica gel, (d)(1). Wash sides of column with ca 20 mL cyclohexane and stir to disperse silica gel. When settling of silica gel slows, drain cyclohexane to aid settling, leaving 5–8 cm solv. above silica gel. Slowly add ca 15 g anhyd.  $\text{Na}_2\text{SO}_4$ . Drain cyclohexane to top of  $\text{Na}_2\text{SO}_4$ .

Quant. transfer remaining ext, 26.119, to column with smallest vol. benzene necessary to effect transfer. Elute column with 200 mL cyclohexane-EtOAc (4+1). Collect entire eluate in 300 mL erlenmeyer.

Add few SiC boiling chips, evap. solv. nearly to dryness on steam bath, and quant. transfer residue to 4 dram vial with  $\text{CHCl}_3$ . Evap. solv. to dryness on steam bath under N.

**26.122 Final Thin Layer Chromatography**

Dissolve ext, 26.121, in vol. benzene to give sterigmatocystin concn of ca 5  $\mu\text{g/mL}$  based on preliminary est., 26.120. Stopper vial and shake, preferably with Vortex mixer.

Proceed as in preliminary TLC, 26.120, and spot successively 3.5, 5.0, and two 6.5  $\mu\text{L}$  portions ext. On sample plate, spot 3.5, 5.0, and 6.5  $\mu\text{L}$  quant. ref. std soln. Spot 5  $\mu\text{L}$  std on top of one 6.5  $\mu\text{L}$  sample spot. Develop, make comparisons, and calc. sterigmatocystin concn as in 26.120, correcting for vol. used in preliminary TLC.

**26.123 Confirmation of Sterigmatocystin Identity by Derivative Formation**

On silica gel plate prepd as in 26.031(a), spot twelve 10  $\mu\text{L}$  spots of sample ext, 26.119 or 26.121, successively at 0.5 cm intervals. Approx. 1 cm beyond spot at each end, place 10  $\mu\text{L}$  spots of qual. ref. std soln. Scribe lines between std and sample spots to prevent sample contamination during development.

Develop plates as in 26.120, and examine under longwave UV light. Sterigmatocystin marker spots in end channels fluoresce brick red. Mark band ca 1 cm wide in sample area of plate at same  $R_f$  as sterigmatocystin std spots, being careful not to include any std sterigmatocystin. Collect silica gel from marked area, using suction to pull coating loosened by plate scraper, 26.076(b), into filter portion of device. Pipet 3 mL MeOH into device and swirl with silica gel. Use filter bell to draw MeOH through fritted disk into small flask.

Pipet 1 mL aliquots MeOH soln into 2 sep. 0.5 dram vials. Dispense 5  $\mu\text{L}$  qual. std soln into 2 other sep. 0.5 dram vials. Evap. solv. on steam bath. Treat std-sample pairs as follows: *Pair 1*: To each vial add 500  $\mu\text{L}$  0.1N HCl; cap vial, shake, and heat 30 min on steam bath. Evap. solv. to dryness on steam bath under N. *Pair 2*: To each vial add 500  $\mu\text{L}$  pyridine and 100  $\mu\text{L}$   $\text{Ac}_2\text{O}$ . Cap vial, shake, and heat 30 min on steam bath. Evap. solv. to dryness on steam bath under N.

Add 20  $\mu\text{L}$   $\text{CHCl}_3$  to each vial. Spot 10  $\mu\text{L}$  from each vial on silica gel TLC plate. Spot derivatives in following sequence: Vial 1 reaction product of std, Vial 1 reaction product of sample, Vial 2 reaction product of std, Vial 2 reaction product of sample, and qual. ref. std. Develop plate with acetone- $\text{CHCl}_3$  (5+95) in lined tank equilibrated with same solv.

Examine developed plate under longwave UV light. Compare sample and std spots. Acetate derivative appears as blue fluorescent spot at  $R_f$  ca  $\frac{1}{2}$  that of brick red sterigmatocystin spot. Remove plate, spray with KOH soln, and re-examine under UV light. Sterigmatocystin derivative formed by treatment with aq. HCl is seen as yellow fluorescent spot at  $R_f$  ca  $\frac{1}{4}$  that of sterigmatocystin, which also fluoresces yellow after exposure to KOH. Some unreacted sterigmatocystin may also appear above derivatives. If spots occur from reaction products of sample similar to and at same  $R_f$  as derivatives of std, sterigmatocystin identity is confirmed.

**ZEARALENONE**

(Caution: Zearalenone is estrogen with less potency than DES. Handle with due regard to its biological activity.)

**Corn (22)—Official First Action**

(Other adoptions: American Association of Cereal Chemists Method 45-20: 1976 revisions to AACC Approved Methods, pp. 1–6.)

**26.124**

See 26.026.

**Apparatus**

**26.125****Reagents**

See **26.002**, **26.027(a)** and **(b)**, and in addn:

(a) *Alcohol-chloroform mixt.*—5+95.

(b) *Aluminum chloride soln.*—Dissolve 20 g  $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$  in 100 mL alcohol.

(c) *Zearalenone std soln.*—Det. chromatgc purity of cryst. zearalenone (available from Commercial Solvents Corp., Terre Haute, IN 47808) as in **26.010**. UV absorption in benzene: max.  $\lambda$  317 nm;  $\epsilon$   $6060 \pm 5\%$ . UV absorption spectrum in MeOH: max.  $\lambda$  314, 274, and 236 nm; MW 318;  $\epsilon$   $6000 \pm 5\%$ ,  $13,900 \pm 5\%$ ,  $30,000 \pm 5\%$ , resp.; GLC purity of trimethylsilyl derivative >98%. Prep. soln contg 50  $\mu\text{g}/\text{mL}$  benzene.

**26.126****Preparation of Sample**

Proceed as in **26.049**.

**26.127****Extraction**

Proceed as in **26.029(a)**.

**26.128****Column Chromatography**

(Caution: See **51.011**, **51.043**, **51.045**, **51.046**, and **51.061**.)

Prep. column, and add 50 mL  $\text{CHCl}_3$  ext and 150 mL hexane wash as in **26.030(a)**. Wash column with 150 mL hexane and elute zearalenone with 250 mL acetone-benzene (5+95).

**26.129****Liquid-Liquid Partition**

Add few SiC chips to eluate contg zearalenone and evap. to near dryness on steam bath, preferably under gentle stream of N. Transfer residue to 60 mL separator with four 10 mL hexane washes. Finally, rinse with 10 mL  $\text{CH}_3\text{CN}$  and transfer to separator. Shake, and let phases sep. Sep.  $\text{CH}_3\text{CN}$  (lower) phase and ext hexane layer with 5 mL  $\text{CH}_3\text{CN}$ . Combine  $\text{CH}_3\text{CN}$  fractions and evap. to dryness in rotary vac. evaporator. Transfer to vial with  $\text{CHCl}_3$ . Evap., preferably under gentle stream of N. Seal with polyethylene stopper and cap. Save for TLC.

**26.130****Preparation of Plates for Thin Layer Chromatography**

Proceed as in **26.031(a)**, except that zearalenone replaces aflatoxin as test mycotoxin.

**26.131****Thin Layer Chromatography**

To residue, **26.129**, add 500  $\mu\text{L}$  benzene, seal with stopper, and shake vigorously on tube shaking machine to dissolve. For preliminary plate, apply 10  $\mu\text{L}$  benzene soln to 2 spots. On one spot superimpose 5  $\mu\text{L}$  zearalenone std soln, **26.125(c)**, for internal std, and apply 5  $\mu\text{L}$  zearalenone std soln to third spot.

Develop plate with alcohol- $\text{CHCl}_3$  (5+95), alcohol- $\text{CHCl}_3$  (3.5+96.5), HOAc-benzene (5+95), or HOAc-benzene (10+90), in lined, equilibrated tank ca 40 min. Compare spots presumed to be zearalenone with std. Zearalenone has greenish-blue fluorescence under shortwave UV (256 nm) at  $R_f$  ca 0.5 and is not visible under longwave UV light except at high concns. Examine sample spot contg internal std to verify identity of zearalenone. When presence of zearalenone is suspected, spray plates with  $\text{AlCl}_3$  soln, heat 5 min at  $130^\circ$ , and examine under longwave UV light (365 nm). Zearalenone fluoresces blue under longwave UV light after spraying with  $\text{AlCl}_3$  soln.

If zearalenone is detected in sample soln, perform quant. TLC. Spot 3, 5, and 7  $\mu\text{L}$  zearalenone std soln and 4, 6, and 8  $\mu\text{L}$  sample soln, and develop plate with alcohol- $\text{CHCl}_3$  (5+95) or other appropriate solvs as in par. 2. Compare fluorescent intensities of zearalenone spots of sample with those of std and

det. which sample spot matches that of std. If spots of smallest portion of sample are too intense to match stds, dil. sample soln and rechromatograph.

**26.132****Calculations**

Calc. concn of zearalenone in  $\mu\text{g}/\text{kg}$  corn:

$$\mu\text{g}/\text{kg} = (S \times Y \times V)/(X \times W),$$

where  $S$  =  $\mu\text{L}$  zearalenone std soln equal to unknown;  $Y$  = concn of zearalenone std soln,  $\mu\text{g}/\text{mL}$ ;  $V$  =  $\mu\text{L}$  of final diln of sample ext;  $X$  =  $\mu\text{L}$  sample ext spotted giving fluorescent intensity equal to  $S$  (zearalenone std soln); and  $W$  = g sample applied to column (10 g). If final ext diln does not represent 10 g, calc. correct sample wt and substitute.

**MARINE TOXINS****26.133 Paralytic Shellfish Poison**

See **18.079–18.085**.

**PHYTOTOXINS****Cyanogenetic Glycosides in Feeds and Similar Materials (23)****26.134 Qualitative Test—Official Final Action**

Prep. Na picrate paper by dipping strips of filter paper into 1% picric acid acid soln and drying, then dipping into 10%  $\text{Na}_2\text{CO}_3$  soln and drying. Store these papers in stoppered bottle.

Finely chop small amt of plant material and place in test tube. Insert piece of moistened Na picrate paper in tube, taking care that it does not come in contact with sample. Add few drops  $\text{CHCl}_3$  and stopper tube tightly. The Na picrate paper gradually turns orange, then brick red, if plant tissue contains cyanogenetic glycosides. (Test is delicate, and rapidity of change in color depends upon amt of free HCN present. This test works well with fresh plant materials, but relatively dry substances, particularly seeds of various plants, should be ground and moistened with  $\text{H}_2\text{O}$  and allowed to hydrolyze in stoppered test tube contg Na picrate paper. If necessary, small amt of *emulsin* may be added.)

**Hydrocyanic Acid Formed by Hydrolysis of Glycosides in Beans (24)—Official Final Action****26.135 Acid Titration Method**

Place 10–20 g sample, ground to pass No. 20 sieve, in 800 mL Kjeldahl flask, add 100 mL  $\text{H}_2\text{O}$ , and macerate at room temp. 2 hr. Add 100 mL  $\text{H}_2\text{O}$  and steam distil, collecting distillate in 20 mL 0.01N  $\text{AgNO}_3$  acidified with 1 mL  $\text{HNO}_3$ . Before distg, adjust app. so that tip of condenser dips below surface of liq. in receiver. When 150 mL has passed over, filter distillate thru gooch, wash receiver and gooch with little  $\text{H}_2\text{O}$ , and titr. excess  $\text{AgNO}_3$  in combined filtrate and washings with 0.02N KSCN, using Fe alum indicator.

$$1 \text{ mL } 0.02\text{N } \text{AgNO}_3 = 0.54 \text{ mg HCN.}$$

**26.136 Alkaline Titration Method**

Place 10–20 g sample, ground to pass No. 20 sieve, in 800 mL Kjeldahl flask, add ca 200 mL  $\text{H}_2\text{O}$  and let stand 2–4 hr. (Autolysis should be conducted with app. completely connected for distn.) Steam distil, collect 150–160 mL distillate in NaOH soln (0.5 g in 20 mL  $\text{H}_2\text{O}$ ), and dil. to definite vol.

To 100 mL distillate (it is preferable to dil. to 250 mL and titr.

100 mL aliquot) add 8 mL 6N  $\text{NH}_4\text{OH}$  and 2 mL 5% KI soln and titr. with 0.02N  $\text{AgNO}_3$ , using microburet. End point is faint but permanent turbidity and may be easily recognized, especially against black background.

1 mL 0.02N  $\text{AgNO}_3$  = 1.08 mg HCN. (Ag equiv. to 2 CN.)

## 27. Nuts and Nut Products (1)

### Volume of Packaged Nuts (2)—Official Final Action

#### 27.001

#### Apparatus

(a) *Graduated cylinders*.—(1) *For less than 500 mL nuts*.—Use 500 mL cylinder with ca 4.7 cm id. (2) *For 500 mL or greater volume of nuts*.—Use 1 L cylinder with ca 5.7 cm id.

(b) *Balance*.—Accurate to 0.01 oz or 0.25 g.

(c) *Funnel*.—With min. opening of 3.8 cm diam. (suitable funnel may be shaped from smooth cardboard).

#### 27.002

#### Determination

Open container and pour nuts loosely into vertical graduate (do not tilt) fitted with funnel. Without shaking, est. location of horizontal plane representing av. ht of product, read vol. nuts, and record max. vol.

Raise graduate 5 cm and drop vertically onto level, firm, resilient surface (do not tamp). Repeat total of 5 times and observe vol. as above. Repeat in successive 5-drop increments until nuts have so settled that vol. decreases  $\leq 2\%$  in last 5-drop increment. Read vol. as above and record as "min. vol." Arithmetical av. of "max," and "min." vol. = mean vol.

#### 27.003 Preservation of Sample—Procedure

Store sample in air-tight container at 5–10°. Store meats in glass containers only.

#### 27.004 Preparation of Sample—Procedure

(a) *Nuts in shell*.—Remove meats from shells, and sep. all shell particles from meats. Skin or spermoderm should be included with meat in all nuts, including peanuts and coconuts unless specifically excluded by description. Prep. sepd meats as in (b).

(b) *Nut meats, shredded coconut, or small pieces*.—Grind  $\geq 250$  g twice thru Enterprise No. 5 food chopper, equipped with revolving knife blade and plate with holes ca 3 mm diam. (Other types of food choppers, graters, or comminuting devices that give smooth homogeneous paste without loss of oil may be used.) Mix sample well and store in air-tight glass container.

(c) *Nut butters and pastes*.—Transfer sample to container of convenient size and shape, warming semi-solid products, and mix carefully with stiff-blade spatula or knife. (Elec. mixers or stirrers may be used instead if sample is of consistency to give uniform mixt.) Store sample in air-tight glass container.

#### 27.005 Moisture (3)—Official First Action

(Not applicable to high sugar products or products contg glycerol or propylene glycol)

Dry sample representing ca 2 g dry material to const wt (ca 5 hr) at 95–100° under pressure  $\leq 100$  mm Hg (13.3 kPa). Report loss in wt as moisture.

#### 27.006 Crude Fat (4)—Official First Action

(Caution: See 51.011, 51.039, and 51.054.)

(a) *Direct method*.—If large amts of sol. carbohydrates interfere with complete extn of fat, ext with H<sub>2</sub>O before making detn. Ext ca 2 g sample with ether, dried as in 7.055, 16 hr in Soxhlet-type extractor. Evap. ether, dry residue 30 min at 95–100°, cool in desiccator, and weigh; continue this alternate drying and

weighing at 30 min intervals to const wt (1–1.5 hr is usually required).

(b) *Indirect method*.—Proceed as in 27.005; then ext dried substance 16 hr as in (a), and dry as in (a). Report loss in wt as ether ext.

#### 27.007 Crude Protein (5)—Official First Action

Det. N as in 2.057, and multiply result by 5.46 for peanuts and brazil nuts, 5.18 for almonds, and 5.30 for other tree nuts and coconut. (It may be desirable to defat with pet ether.)

#### 27.008 Crude Fiber—Official First Action

See 7.065.

#### 27.009 Ash (6)—Official First Action

See 31.012, or 31.013 if added chlorides are present.

#### 27.010 Reducing Sugars (6)—Official Final Action

Prep. sample as in 1st and 2nd par. of 7.079. Proceed as in 31.038, using 25 mL aliquot (representing 2 g sample). Express results as glucose or invert sugar.

#### 27.011 Sucrose (6)—Official Final Action

See 7.079.

#### 27.012 Sodium Chloride (6)—Official Final Action

To 2 g prepd sample, 27.004, in Pt dish, add and thoroly incorporate 10 mL 10% Ca(OAc)<sub>2</sub> soln. For nut butters and pastes, disperse sample in 10 mL acetone before adding Ca(OAc)<sub>2</sub>, and remove acetone at room temp. with air current. Dry on steam bath, and ash in furnace at lowest visible red heat (550°). (Complete ashing is not necessary.)

Dissolve ash in 25 mL HNO<sub>3</sub> (1+3), add known vol. 0.1N AgNO<sub>3</sub>, more than enough to ppt all Cl, heat to bp, cool, add 5 mL ferric indicator, 6.019(e), and titr. excess Ag with 0.1N NH<sub>4</sub>SCN, 50.030(b) until soln turns permanent light brown. Calc. Cl as NaCl, after correcting for any Cl in the Ca(OAc)<sub>2</sub> soln.

#### 27.013 Water-Insoluble Inorganic Residue Official First Action

See 44.032★.

#### 27.014 Mycotoxins

See Chap. 26.

### PEANUT BUTTER

#### 27.015 Preliminary Examination—Procedure

Make microscopic examination to detect addn of starch or any off-grade material not identifiable chem.

#### 27.016 Starch (7)—Official First Action

Weigh 4–5 g sample by difference into 250 mL centr. bottle and ext twice with 50 mL portions pet ether, shaking 5 min each time. Wash down sides of bottle with pet ether, centr., and pour off solv., disregarding opalescence. Warm bottle to drive

off remaining solv., transfer residue to mortar, and grind. Return fine powder to bottle with aid of 100 mL 10% NaCl soln. Shake bottle 15 min, wash down sides NaCl soln, centrf. well, and pour off supernate, disregarding opalescence. Repeat washing twice.

Ext in same manner, once with 70% alcohol and once with H<sub>2</sub>O, shaking 1–2 min each time. Drain bottle several min., chill, and from pipet add 100 mL HCl (20.5–21.0 g HCl/100 mL) at temp.  $\leq 15^{\circ}$ . Shake vigorously 3 min, centrf. well, and pour off soln thru cotton pledget in funnel stem. Cool soln to temp. at which the HCl was added, and pipet off 50 mL into nursing bottle contg 115 mL alcohol. Shake with whirling motion 1 min, let stand 2 min, centrf. 2 min, pour off thru weighed gooch contg thin asbestos pad, and add 50 mL 70% (v/v) alcohol to ppt. Stopper bottle, shake vigorously, wash down sides with the 70% alcohol, centrf. lightly, and pour off thru crucible. Repeat once with 70% alcohol and once with alcohol. Dry crucible and contents 1.5 hr at 130° in air, or 5 hr at 98–100° *in vacuo*. Cover crucible, place in desiccator contg efficient desiccant, and weigh when crucible reaches room temp.

#### SHREDDED COCONUT

##### 27.017 ★ Glycerol—Official First Action ★

Ext. 4 times, with suction, 4 g shredded coconut (dried 5–6 hr *in vacuo* at 70°) on filter (fritted glass buchner is most convenient), using 50 mL pet ether (bp  $< 65^{\circ}$ ) for each extn, and allowing 3 min intervals between extns. Use flat-end glass rod for stirring. After removing fat, ext residue on filter with four 50 mL portions absolute alcohol, allowing 3 min intervals with stirring, as before. Dil. ext to 250 mL with absolute alcohol at room temp.

Pipet 100 mL into 500 mL erlenmeyer, and add 5 mL H<sub>2</sub>O and paste made by adding hot H<sub>2</sub>O to 2 or 3 g Ba(OH)<sub>2</sub> in small mortar. Heat mixt. on steam bath to bp and boil ca 1 min; transfer to 250 mL centrf. bottle and centrf. at 2000 rpm ca 5 min. Transfer clear liq. to large porcelain dish and wash residue in centrf. bottle with 50–75 mL absolute alcohol, stirring with glass rod and centrfg as before. Evap. on steam bath at temp.  $< 70^{\circ}$  to few drops, or almost dryness.

Transfer to 50 mL g-s graduate with 10 mL absolute alcohol and wash dish with two 5 mL portions absolute alcohol. Further wash dish with three 10 mL portions anhyd. ether, shaking g-s graduate thoroly after each addn of anhyd. ether. Transfer to sediment tube and centrf. 10 min at 3200 rpm. Transfer clear soln in sediment tube to evapg dish, preferably Pt, and wash sediment tube with 25 mL of mixt. of absolute alcohol and anhyd. ether (2+3), stirring with glass rod and centrfg as before. Evap. on steam bath at 85–90° to ca 5 mL, add 20 mL H<sub>2</sub>O, and evap. to ca 5 mL; repeat this operation twice. Transfer residue with hot H<sub>2</sub>O to 50 mL vol. flask and proceed as in 30.080 ★.

## 28. Oils and Fats

### 28.001 Preparation of Sample—Procedure

Melt solid fats and filter, using hot H<sub>2</sub>O funnel or similar app. Make detns on samples of this melted, homogeneous mass. Filter oils that are not clear. To retard rancidity, keep oils and fats in cool place and protect from light and air.

### Moisture and Volatile Matter (7)

#### 28.002 Vacuum Oven Method—Official Final Action

Soften sample, if necessary, by gentle heat, taking care not to melt it. When soft enough, mix thoroly with effective mech. mixer.

Weigh  $5 \pm 0.2$  g prepd sample into Al moisture dish ca 5 cm diam. and 2 cm deep with tight-fit slip-over cover. Dry to const wt in vac. oven at uniform temp. 20–25° above bp of H<sub>2</sub>O at working pressure, which should be  $\leq 100$  mm Hg (13.3 kPa). Cool in efficient desiccator 30 min and weigh. Const wt is attained when successive 1 hr drying periods show addnl loss of  $\leq 0.05\%$ . Report % loss in wt as moisture and volatile matter.

### Specific Gravity (Apparent) at 25/25° Official Final Action

#### 28.003 Standardization of Pycnometer

(Caution: See 51.023 and 51.030.)

Carefully clean pycnometer (ca 50 mL capacity, Kimble Products No. 15123, or equiv.) by filling with chromic acid cleaning soln and letting stand several hr. Empty pycnometer and rinse thoroly with H<sub>2</sub>O; fill with recently boiled H<sub>2</sub>O previously cooled to ca 20°, and place in const temp. bath at 25°. After 30 min, adjust H<sub>2</sub>O level to proper point on pycnometer and stopper; remove from bath, wipe dry with clean cloth or towel, and weigh. Empty pycnometer, rinse several times with alcohol and then ether, let dry completely, remove ether vapor, and weigh. Det. wt of contained H<sub>2</sub>O at 25° by subtracting wt pycnometer from its wt when filled with H<sub>2</sub>O.

#### 28.004 Determination

Fill clean, dry pycnometer with sample previously cooled to ca 20°, place in const temp. bath 30 min at 25°, adjust oil level to proper point on pycnometer, and stopper. Remove from bath, wipe dry, and weigh as in 28.003. Subtract wt empty pycnometer from its wt when filled with oil and divide difference by wt H<sub>2</sub>O at 25°, as detd in 28.003. Quotient is sp gr at 25/25° (apparent).

If sp gr at 20/20° is required, proceed as above and as in 28.003 but subtract 5° from each temp. specified.

#### 28.005 Temperature Correction for Specific Gravity of Oils (2)—Official Final Action

If sp gr of oil is detd at other than std temp., approx. sp gr at 25/25° may be calcd as follows:

$$G = G' + 0.00064(T - 25^\circ),$$

where  $G$  = sp gr at 25/25°,  $G'$  = sp gr at  $T/25^\circ$ ,  $T$  = temp. at which sp gr was detd, and 0.00064 = mean correction for 1°.

### Index of Refraction—Official Final Action

#### 28.006 General Directions

Det. index of refraction ( $n$ ) with any std instrument, reading oils at 20 or 25° and fats at 40°. Place instrument so that diffused daylight or some form of artificial light such as Na vapor lamp can be used for illumination. Circulate stream of const temp. ( $\pm 0.2^\circ$ ) H<sub>2</sub>O thru prisms. Approx. temp. corrections of butyrorefractometer readings may be made by following formula:

$$R = R' + K(T' - T),$$

where  $R$  = reading reduced to std temp.,  $R'$  = reading obtained at temp.  $T'$ ,  $T$  = std temp., and  $K$  = 0.55 for fats and 0.58 for oils.

Readings of instruments that give  $n$  directly can be reduced to std temp. by substituting factor 0.000365 for 0.55 and 0.000385 for 0.58 in formula. As temp. rises,  $n$  falls. Instrument used may be stdzd with H<sub>2</sub>O at 20°, theoretical  $n$  of H<sub>2</sub>O at that temp. being 1.3330. Any correction found should be made on all readings. Index of refraction varies with density and in same direction.

#### 28.007 By Means of Abbé Refractometer

To charge instrument, open double prism by means of screw head and place few drops sample on prism or, if preferred, open prisms slightly by turning screw head and pour few drops sample into funnel-shape aperture between prisms. Close prisms firmly by tightening screw head. Let instrument stand few min before reading, so that temp. of sample and instrument will be same. Clean prisms between readings by wiping off oil with soft cloth, then with cotton pad moistened with solv. (e.g., trichloroethylene, toluene, or pet ether), and let dry.

Method of measurement is based upon observation of position of *border line of total reflection* in relation to faces of flint glass prism. Bring this border line into field of vision of telescope by rotating double prism by means of alidade in following manner: Hold sector firmly and move alidade backward or forward until field of vision is divided into light and dark portion. Line dividing these portions is "border line," and, as a rule, will not be sharp line but band of color. Colors are eliminated by rotating screw head of compensator until sharp, colorless line is obtained. Adjust border line so that it falls on point of intersection of cross hairs. Read  $n$  of substance directly on scale of sector, estg 4th decimal place. Take  $\geq 3$  readings, approaching intersection alternately from one field to other, and average. Range of readings should be  $\leq 0.0002$ . Check correctness of instrument as in 28.006, or with quartz plate that accompanies it, using monobromonaphthalene, ( $n_{20^\circ} = 1.6587$ ), and make necessary correction in reading.

#### 28.008 By Means of Zeiss Butyrorefractometer

Place 2 or 3 drops filtered sample on surface of lower prism. Close prisms and adjust mirror until it gives sharpest reading. If reading is indistinct after running const temp. H<sub>2</sub>O thru instrument for some time, sample is unevenly distributed on prism surfaces. As  $n$  is greatly affected by temp., use care to keep temp. const. Carefully adjust instrument, using std fluid supplied with it. Convert instrument reading to  $n$  from Table 28:01.

**Table 28:01 Butyrefractometer Readings and Indices of Refraction**

Reading	Index of Refraction	Reading	Index of Refraction
40.0	1.4524	60.0	1.4659
40.5	1.4527	60.5	1.4662
41.0	1.4531	61.0	1.4665
41.5	1.4534	61.5	1.4668

59.5	1.4656	79.5	1.4780

**Melting Point of Fats and Fatty Acids—Official Final Action****Wiley Method****28.009****Reagent**

*Alcohol-water mixture.*—Sp gr should be same as that of fat to be examined. Prep. by sep. boiling H<sub>2</sub>O and alcohol 10 min to remove dissolved gases. While still hot, pour H<sub>2</sub>O into test tube until it is almost half full. Nearly fill test tube with hot alcohol, pouring it down side of inclined tube to avoid too much mixing. If alcohol is added after the H<sub>2</sub>O has cooled, air bubbles will make mixt. unfit for use.

**28.010****Determination**

Let melted and filtered fat fall 15–20 cm from dropping tube upon piece of ice or upon surface of cold Hg. Disks thus formed should be 1–1.5 cm diam. and weigh ca 200 mg. Remove disks when solid, and let stand 2–3 hr to obtain normal mp.

Alternatively, disks may be prepd using app. consisting of Al plate ca 3 mm thick and 100 mm sq with perforations ca 10 mm diam. and steel plate ca 10 mm thick and 150 mm sq. Thoroughly chill steel plate in refrigerator and place Al plate on top (surfaces should be flush). Pour melted and filtered fat into holes of Al plate and let stand in refrigerator  $\geq 2$  hr. Remove fat above surface of Al plate and remove disks.

Place 30  $\times$  3.5 cm test tube, contg alcohol-H<sub>2</sub>O mixt., in tall 35  $\times$  10 cm beaker contg ice and H<sub>2</sub>O, and leave until mixt. is cold. Drop disk of fat into tube. It will sink immediately to point where density of alcohol-H<sub>2</sub>O mixt. is exactly equiv. to its own. Lower accurate thermometer, that can be read to 0.1°, into test tube until bulb is just above disk. To secure even temp. in all parts of alcohol-H<sub>2</sub>O mixt. around disk, stir gently with thermometer. Slowly heat H<sub>2</sub>O in beaker, constantly stirring with air stream or other suitable device.

When temp. of alcohol-H<sub>2</sub>O mixt. rises to ca 6° below mp of fat, disk of fat begins to shrivel and gradually rolls up into irregular mass. Lower thermometer until fat particle is even with center of bulb. Rotate thermometer bulb gently and so regulate heat that ca 10 min is required for last 2° increase in temp. As soon as fat mass becomes spherical, read thermometer. This is Wiley mp. At this point, temp. of bath must be  $\leq 1.5^\circ$  above mp of sample. Conduct 2 addnl detns exactly as above. Second and third results should agree closely.

If edge of disk touches side of tube, make new detn.

**28.011 Capillary Tube Method (3)**

Draw ca 10 mm melted and filtered fat into thin-wall capillary tube, 1 mm id. Seal end of tube with sample in small flame. Do not burn fat. Hold tubes contg fat overnight (ca 16 hr) in refrigerator at 4–10°. Attach tube to accurate thermometer graduated to 0.2°, so that lower end is even with bottom of Hg bulb. Suspend in 600 mL beaker half filled with H<sub>2</sub>O so that thermometer is immersed ca 30 mm. Starting 8–10° below mp of sample, apply heat so as to increase bath temp. ca 0.5°/min, agitating H<sub>2</sub>O in bath by small stream of air or with slow stirrer. Take as mp temp. at which substance becomes transparent. (Magnifying glass is useful to detect complete melting.) Report av. of 3 detns (should agree within 0.5°).

**Titer Test (4)—Official Final Action****28.012 Specifications for Titer Test Thermometers**

*Type.*—Etched stem, glass.

*Liquid.*—Mercury.

*Range and subdivision.*—Minus 2 to +68° in 0.2°.

*Total length.*—385–390 mm.

*Stem.*—Constructed of suitable thermometer tubing of either plain or lens front type. Diam., plain front type: 6–7 mm; diam., lens front type: cross section of stem must be such that it will pass thru 8 mm ring gage but not enter 5 mm slot gage.

*Bulb.*—Corning normal or equally suitable thermometric glass. Length, 15–25 mm; diam., 5.5 mm to not greater than that of stem.

*Distance from bottom of bulb to -2° mark.*—50–60 mm.

*Distance to 68° mark from top of thermometer.*—20–35 mm.

*Length of unchanged capillary.*—Between highest graduation and expansion chamber, 10 mm.

*Expansion chamber.*—To permit heating to  $\geq 85^\circ$ . Space above Hg to be evacuated or filled with N or other suitable gas.

*Top finish.*—Glass ring.

*Graduation.*—All lines, figures, and letters to be clear-cut and distinct. Each degree mark to be longer than remaining lines. Graduations to be numbered at 0 and at each multiple of 2°.

*Immersion.*—45 mm.

*Marking.*—"A.O.A.C. Titer Test," serial number, and manufacturer's name or trademark must be etched on stem. Words "45 mm immersion" must also be etched on stem, as well as line extending around stem 45 mm above bottom of bulb.

*Scale error.*—Error at any point on scale must be  $\leq 0.2^\circ$ .

*Standardization.*—Thermometer must be stdzd at ice point

and at intervals of ca 20°, for condition of 45 mm immersion, and for av. stem temp. of emergent Hg column of 25°.

**Case.**—Thermometer must be supplied in suitable case on which appears markings "A.O.A.C. Titer Test," "−2° to +68° in 0.2°."

**Note:** For interpreting these specifications, following definitions apply:

Total length is over-all length of finished instrument. Diam. is that measured with ring gage or micrometer. Length of bulb is distance from bottom to beginning of enamel backing. Top of thermometer is top of finished instrument.

ASTM 36C titer test thermometer is satisfactory (Fisher Scientific Co. or Scientific Products, Inc.).

### 28.013

### Apparatus

Stirring titer assembly, as shown in Fig. 28:01, consisting of 2 L beaker, 450 mL wide-mouth bottle (ht 190 mm, id of neck, 38 mm), titer test tube (25 × 100 mm), and stirrer (2–3 mm od, one end bent in form of loop, 19 mm diam.).

### 28.014

### Determination

Heat 110 g *glycerol-KOH soln* (25 g KOH in 125 g glycerol) to 150° in 800 mL beaker and add 50 mL oil or melted fat, previously filtered if necessary to remove foreign substances. (Altho saponification often takes place almost immediately, continue heating and frequent stirring 15 min. Do not heat >150°.)

When saponification is complete, usually indicated by perfectly homogeneous soln, cool slightly and add 200–300 mL H<sub>2</sub>O. After complete soln of the soap, add with stirring 50 mL dil. H<sub>2</sub>SO<sub>4</sub> (16 mL H<sub>2</sub>SO<sub>4</sub> in 70 mL H<sub>2</sub>O). Heat soln, with frequent stirring and addn of H<sub>2</sub>O if necessary, until layer of fatty acids is completely melted and clear. Siphon off aq. acid layer, add H<sub>2</sub>O to fatty acids, boil 2–3 min, and again siphon off aq. layer. Repeat treatment with H<sub>2</sub>O until wash H<sub>2</sub>O is neut. to Me orange. Remove fatty acids so as not to include H<sub>2</sub>O, and filter while melted thru rapid paper. Heat to 130° on hot plate to remove traces of H<sub>2</sub>O and pour fatty acids into titer tube to ht of 57 mm from bottom. If H<sub>2</sub>O is present in fatty acids, decant, refilter, and reheat.

Fill H<sub>2</sub>O bath and adjust to 20° for all samples with titers ≥35°, and to 15–20° below titer for samples with titers <35°. (H<sub>2</sub>O level should be 1 cm above sample level.) Place test tube contg fatty acids in app., Fig. 28:01. Insert thermometer to immersion mark and equidistant from sides of tube. Stir vertically with stirring rod at rate of 100 complete up-and-down motions/min, starting agitation while temp. is ≥10° above titer point. (Stirrer should move thru vertical distance of ca 3.8 cm. If preferred, stirring may be performed mech.) Continue stirring until temp. remains const 30 sec or begins to rise in <30 sec interval. Immediately discontinue stirring and observe rise in temp. Report as titer highest point reached by thermometer. Duplicate detns should normally agree within 0.2°.

### 28.015 ★ Acetyl Value (5)—Official Final Action ★

See 26.016–26.017, 10th ed.

### Hydroxyl Value (6)—Official Final Action

### American Oil Chemists' Society Method

(Hydroxyl value is number of mg KOH equiv. to hydroxyl content of 1 g sample. Applicable to fatty oils and derivatives such as fatty alcohols, mono- and diglycerides, and hydroxystearic acid.)

### 28.016

### Reagents

(a) *Pyridine*.—Reagent grade, redistd at 114–115°.

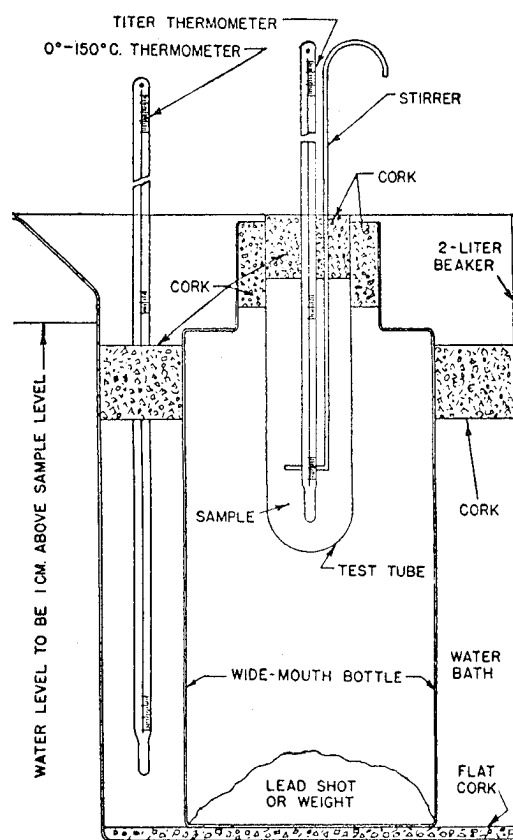

FIG. 28:01—Titer stirring assembly

(b) *Acetic anhydride*.—ACS, fresh.

(c) *Pyridine-acetic anhydride reagent*.—Mix 3 vols reagent (a) with 1 vol. (b) just before use.

(d) *n-Butyl alcohol*.—Reagent grade. Neutze with 0.5N KOH to faint pink phthln end point.

(e) *Alcoholic potassium hydroxide std soln*.—0.5N. (Should be ≥0.5N so that blank titers do not require refilling of 50 mL buret.)

### 28.017

### Determination

(Caution: See 51.018 and 51.022.)

According to expected hydroxyl value, weigh following amts of sample into 250 mL  $\frac{1}{2}$  g-s erlenmeyers to nearest mg for acetylation:

Hydroxyl Value	Weight, g
0–20	10 ± 0.1
20–50	5
50–100	3
100–200	2

Weigh 9.0–11.0 g sample into another flask for acidity detn. (For fatty acids such as hydroxystearic acid, take 0.9–1.1 g.)

Pipet 5.0 mL reagent (c) into flask contg acetylation sample. For samples with 0–20 hydroxyl value, add addnl 5 mL pyridine. Mix thoroly by gentle swirling. Pipet 5 mL reagent (c) (and 5 mL pyridine, if used in acetylation) into another flask for reagent blank. Place flasks on steam bath under  $\frac{1}{2}$  reflux condenser and heat 1 hr. (Do not use hot plate or mantle.) Add 10 mL H<sub>2</sub>O thru

★ Surplus method—see inside front cover.

condenser and heat addnl 10 min. Let flasks cool with condenser attached. Add 25 mL *n*-BuOH, ca half thru condenser, remove condenser, and use rest to wash down sides of flask. Add 1 mL phthln and titr. to faint pink end point with 0.5*N* alc. KOH.

Add 10 mL pyridine, neutzd to phthln, to sample for acidity detn. Swirl gently to mix, add 1 mL phthln, and titr. to faint pink end point with 0.5*N* alc. KOH.

Hydroxyl value =  $[B + (W \times V/C) - S] \times \text{normality} \times 56.1/W$ , where *V* = mL KOH for acidity titrn, *B* = mL KOH for reagent blank, *C* = g sample for acidity titrn, *S* = mL KOH for acetylated sample, *W* = g sample used for acetylation.

#### Iodine Absorption Number—Official Final Action

(All reports should specify method used)

##### Hanus Method

#### 28.018

##### Reagent

**Hanus iodine soln.**—Dissolve 13.2 g pure I in 1 L HOAc that shows no reduction with dichromate and H<sub>2</sub>SO<sub>4</sub>. Add enough Br to double halogen content as detd by titrn (ca 3 mL). The I may be dissolved by heating, but soln should be cold when Br is added. Hanus I soln may also be prepd as follows: Measure 825 mL HOAc and dissolve 13.615 g I in it with aid of heat. Cool, and titr. 25 mL with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, **50.037–50.038**. Measure another portion of 200 mL HOAc and add 3 mL Br. To 5 mL of this soln add 10 mL 15% KI soln, and titr. with the 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Calc. vol. Br soln required to double halogen content of remaining 800 mL I soln as follows:

$X = B/C$ , where *X* = mL Br soln required; *B* = 800 × thiosulfate equiv. of 1 mL I soln; and *C* = thiosulfate equiv. of 1 mL Br soln. If necessary, reduce mixed soln to proper concn by diln with HOAc.

#### 28.019

##### Determination

Weigh ca 0.5000 g fat, or 0.2500 g oil (0.1000–0.2000 g of oils that have high absorbent power), into 500 mL g-s flask or bottle and dissolve in 10 mL CHCl<sub>3</sub>. With pipet, add 25 mL Hanus I soln, draining pipet definite time, and let stand 30 min in dark, shaking occasionally. (For accurate results use exact time. Excess I should be ≥60% of amt added.)

Add 10 mL 15% KI soln, shake thoroly, and add 100 mL freshly boiled and cooled H<sub>2</sub>O, washing down any free I on stopper. Titr. I with std 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, adding it gradually, with const shaking, until yellow soln turns almost colorless. Add few drops starch indicator, **2.144(b)**, and continue titrn until blue entirely disappears. Toward end of titrn, stopper bottle and shake violently, so that any I remaining in soln in CHCl<sub>3</sub> may be taken up by KI soln.

Conduct 2 blank detns along with detn on sample. Number of mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> required by blank (*B*) minus mL used in detn (*S*) gives Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> equiv. of I absorbed by the fat or oil. Calc. % by wt of I absorbed (I number, Hanus method).

$$\text{I number} = [(B - S) \times N \times 12.69]/\text{g sample},$$

where *N* is normality of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln.

##### Wijs Method (7)

#### 28.020

##### Reagents

(Caution: See **51.018**, **51.022**, and **51.047**.)

**Wijs iodine soln.**—(1) Dissolve 13 g resublimed I in 1 L HOAc, and pass in dried (thru H<sub>2</sub>SO<sub>4</sub>) Cl until original Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> titrn of soln is not quite doubled. (Characteristic color change at end

point indicates proper amt of Cl. Convenient method is to reserve some of original I soln, add slight excess of Cl to bulk of soln, and bring to desired titer by readdns of reserved portion.) Or: (2) Dissolve 16.5 g ICl in 1 L HOAc.

Store in amber bottle sealed with paraffin until ready for use. Wijs solns are sensitive to temp., moisture, and light. Store in dark at <30°. Det. I/Cl ratio as follows:

**Iodine content.**—Pipet 5 mL Wijs soln into 500 mL erlenmeyer contg 150 mL satd Cl-H<sub>2</sub>O and some glass beads. Shake, heat to bp, and boil briskly 10 min. Cool, add 30 mL H<sub>2</sub>SO<sub>4</sub> (1+49) and 15 mL 15% KI soln, and titr. immediately with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

**Total halogen content.**—Pipet 20 mL Wijs soln into 500 mL erlenmeyer contg 150 mL recently boiled and cooled H<sub>2</sub>O and 15 mL 15% KI soln. Titr. immediately with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

$$I/Cl = 2X/(3B - 2X),$$

where *X* = mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> required for I content and *B* = mL required for total halogen content. I/Cl ratio must be 1.10±0.1.

#### 28.021

##### Determination

Use sample wt calcd as 26/expected I value, or from following table:

I Value	g Sample <sup>a</sup>	Accuracy, mg
3	10.58–8.46	±5.
10	3.17–2.54	0.2
20	1.59–1.27	0.2
40	0.79–0.63	0.2
80	0.40–0.32	0.2
120	0.26–0.21	0.2
160	0.20–0.16	0.2
200	0.16–0.13	0.2

<sup>a</sup> For 100 and 150% excess, resp.

Weigh melted and filtered sample into clean, dry, 500 mL g-s flask contg 20 mL CCl<sub>4</sub>. With pipet, add 25 mL I soln, draining pipet definite time. Excess of I should be 50–60% of amt added, that is, 100–150% of amt absorbed. Swirl, and let bottle stand in dark 30 min at 25±5°. Let samples with I values >150 (linseed and perilla) stand 1 hr.

Add 20 mL 15% KI soln and 100 mL recently boiled and cooled H<sub>2</sub>O. Titr. the I with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, **50.037–50.038**, added gradually, shaking constantly until yellow soln turns almost colorless. (Vigorous mag. stirring is convenient.) Add few drops starch indicator, **2.144(b)**, and continue titrn until blue entirely disappears. Toward end of reaction, stopper bottle and shake violently so that any I remaining in soln in CCl<sub>4</sub> may be taken up by KI soln.

Conduct 2 detns on blanks in same manner as sample, but without fat. Slight variations in temp. appreciably affect titer of I soln, as HOAc has high coefficient of expansion. It is essential, therefore, that blanks and detns on sample be made at same time. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> equiv. of I absorbed by sample taken = mL std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln required by blank (*B*) – mL used in detn (*S*). Calc. % by wt of I absorbed as in **28.019** and report as I number, Wijs method.

#### Peroxide Value—Official Final Action

##### American Oil Chemists' Society Method (8)

#### 28.022

##### Reagents

(a) **Acetic acid-chloroform soln.**—Mix 3 vols HOAc with 2 vols CHCl<sub>3</sub>, USP.

(b) **Potassium iodide soln, saturated.**—Dissolve excess KI in freshly boiled H<sub>2</sub>O. Excess solid must remain. Store in dark. Test daily by adding 0.5 mL to 30 mL HOAc-CHCl<sub>3</sub>, (a); then add 2 drops 1% starch soln, **2.144(b)**. If soln turns blue, requiring >1 drop 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> to discharge color, prep. fresh soln.

(c) *Sodium thiosulfate std solns.*—0.1 and 0.01*N*. Prep. and stdze as in **50.037–50.038**. For 0.01*N*, dil. 0.1*N* with freshly boiled and cooled H<sub>2</sub>O.

**28.023****Determination**

(a) *Fats and oils.*—Weigh  $5.00 \pm 0.05$  g sample into 250 mL g-s erlenmeyer. Add 30 mL HOAc-CHCl<sub>3</sub>, (a), and swirl to dissolve. Add 0.5 mL satd KI soln, (b), from Mohr pipet, let stand with occasional shaking 1 min, and add 30 mL H<sub>2</sub>O. Slowly titr. with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> with vigorous shaking until yellow is almost gone. Add ca 0.5 mL 1% starch soln, **2.144(b)**, and continue titrn, shaking vigorously to release all I from CHCl<sub>3</sub> layer, until blue just disappears. If <0.5 mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is used, repeat detn with 0.01*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

Conduct blank detn daily (must be  $\leq 0.1$  mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>). Subtract from sample titrn.

Peroxide value (milliequiv. peroxide/kg sample) =  $S \times N \times 1000 / \text{g sample}$ , where  $S$  = mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> (blank corrected) and  $N$  = normality Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln.

(b) *Margarine.*—Melt sample by heating with const stirring on hot plate at low heat, or heat in air oven at 60–70°. (Avoid excessive heat and long exposure >40°.) When completely melted, hold in warm place until aq. portion and most of solids have settled. Decant oil into clean beaker and filter thru Whatman No. 4, or equiv. paper. Do not reheat unless necessary to obtain clear filtrate. Proceed as in (a).

**28.024 ★ Thiocyanogen Number ★**  
**Official First Action**

(Caution: Thiocyanogen is toxic. See **51.018**, **51.022**, **51.047**, and **51.050**.)

See **26.026–26.027**, 10th ed.

**Saponification Number (Koettstorfer Number)**  
**Official Final Action**

**28.025****Reagent**

*Alcoholic potassium hydroxide soln* (JAOAC **19**, 427(1936)).—(1) Reflux 1.2 L alcohol 30 min in distg flask with 10 g KOH and 6 g granulated Al (or Al foil). Distil and collect 1 L after discarding first 50 mL. Dissolve 40 g KOH in this 1 L alcohol, keeping temp. <15° while dissolving alkali. Keep soln in g-s bottle. Or, (2) crush 40 g KOH in 185 mm mortar. Add 45 g granulated CaO and grind mixt. to powder. From 1 L alcohol add 100 mL to mortar and transfer to flask, rinsing mortar with several more portions. Add remainder of alcohol to flask, shake mixt.  $\geq 5$  min, and invert beaker over neck of flask. Repeat shaking several times during day. Next morning filter soln into clean, dry, g-s bottle.

**28.026****Determination**

Accurately weigh ca 5 g filtered sample into 250–300 mL erlenmeyer. Pipet 50 mL alc. KOH soln into flask, draining pipet definite time. Connect flask with air condenser and boil until fat is completely saponified (ca 30 min). Cool, and titr. with 0.5*N* HCl, **50.011–50.012**, using phthln. Conduct blank detn along with that on sample, using same pipet for measuring KOH soln and draining same time.

Calc. saponification no. (mg KOH required to saponify 1 g fat)  
=  $28.05 (B - S) / \text{g sample}$ ,  
where  $B$  = mL 0.5*N* HCl required by blank and  $S$  = mL 0.5*N* HCl required for sample.

★ Surplus method—see inside front cover.

**28.027 ★ Soluble Acids—Official Final Action ★**

See **26.030**, 10th ed.

**28.028 ★ Insoluble Acids (Hehner Number) ★**  
**Official Final Action**

See **26.031**, 10th ed.

**Free Fatty Acids in Crude and Refined Oils**

**28.029 National Cottonseed Products Association**  
**Method—Official Final Action**

(a) *In crude oils.*—Weigh 7.05 g well mixed oil into 250 mL flask or 4 oz bottle. Add 50 mL alcohol, previously neutzd by adding 2 mL phthln soln and enough 0.1*N* NaOH to produce faint permanent pink. Titr. with 0.25*N* NaOH, **50.034–50.035**, with vigorous shaking until permanent faint pink appears and persists  $\geq 1$  min. Report as % free fatty acids expressed as oleic acid; mL 0.25*N* NaOH used in titrn corresponds to this %.

(b) *In refined oils.*—To ca 50 mL alcohol in clean, dry 150 mL flask, add few drops of the oil and 2 mL phthln. Place flask in H<sub>2</sub>O at 60–65° until warm, and add enough 0.1*N* NaOH to produce faint permanent pink. Weigh 56.4 g oil into the neutzd alcohol and titr. with 0.1*N* NaOH, **50.034–50.035**, occasionally warming and violently shaking mixt. until same faint permanent pink appears in supernate alcohol. Multiply mL 0.1*N* NaOH by 0.05 and report as % free fatty acids expressed as oleic acid.

Free fatty acids may also be expressed in terms of acid value (mg KOH necessary to neutze 1 g sample). Acid value = % free fatty acids (as oleic)  $\times 1.99$ .

**Crude Fatty Acids (9)—Official First Action**

**AOAC-American Oil Chemists' Society Method**

**28.030****Principle**

Sample is saponified and, after acidification, fatty acids and unsaponifiable matter are removed by continuous extn with hexane. Extn of second sample without acidification yields unsaponifiable matter. Fatty acids are detd by difference.

**28.031****Apparatus**

(a) *Liquid-liquid extractor.*—See Fig. **28.02**. With mag. stirring disk, condenser, and refluxing flask (available as No. 4112A-E, Glencoe Scientific, Inc., 2802 White Oak Dr, Houston, TX 77007).

(b) *Combination hot plate-magnetic stirrer.*—Sargent-Welch Model H, or equiv., to provide mag. stirring at 25 and 80°.

(c) *Heating mantle or other device for refluxing hexane.*

(d) *Rotary evaporator.*—Sargent-Welch No. S-31210, or equiv., which releases vac. with N or He.

**28.032****Reagents**

(a) *Potassium hydroxide soln.*—50%. Dissolve 50 g KOH in H<sub>2</sub>O and dil. to 100 mL with H<sub>2</sub>O.

(b) *Hexane.*—Redistd or residue-free when 200 mL is evapd (Phillips Chemical Co. *n*-hexane has been found satisfactory).

(c) *Nitrogen (low oxygen content) or helium.*

**28.033****Preparation of Sample**

Warm sample to liq., mix thoroly, transfer ca 5 g to 50 mL beaker, and cool. Weigh, with dropper, warm to liq., transfer 2–2.5 g by dropper to reaction vessel contg mag. stirring disk, cool beaker and dropper, and reweigh. Add 50 mL alcohol and 3 mL KOH soln, cover with watch glass, and heat just at bp, with

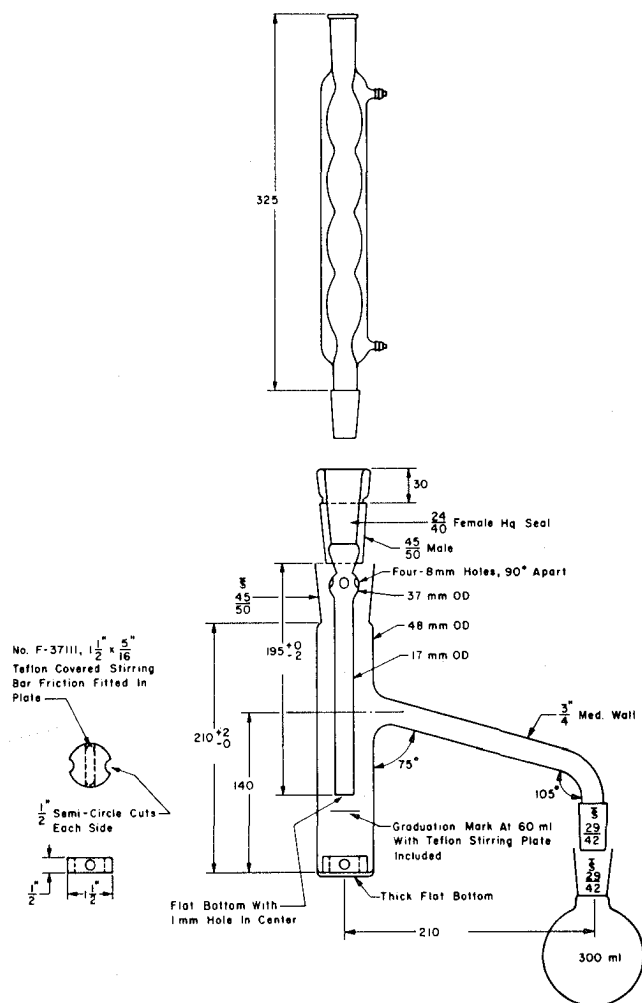

FIG. 28:02—Liquid-liquid extractor

gentle stirring, 30 min. Add alcohol to original vol., add 50 mL  $H_2O$ , and warm if necessary to dissolve soap.

#### 28.034 Total Fatty Acids and Unsaponifiable Matter

Acidify freshly saponified sample by slowly adding 6N HCl (ca 5 mL) to reaction vessel. Test with Me orange indicator to assure that soln is strongly acid. Fill inner tube of extractor with hexane, immediately insert into position in reaction vessel to prevent backflow of aq. soln, and attach condenser. Add 100 mL hexane to r-b flask, add No. 20 SiC boiling chip or inverted mp tube, attach to side arm, and begin refluxing with mag. stirrer rotating at min. speed. While checking to see that emulsions do not rise in reaction vessel, gradually increase rotation to ca 500 rpm and reflux rate to 200–250 drops/min. Continue refluxing with stirring 2.0 hr. Cool r-b flask and filter soln, if cloudy, thru 2–3 cm paper on fritted disk. Remove solv. either on steam bath with stream of N or in rotary evaporator, applying vac. cautiously 1 min, then full vac. with flask immersed in 80° bath addnl 20 min. Cool, release vac. with N, dry outer surface of r-b flask, and weigh. Repeat 80° vac. step, if necessary, to assure const wt. Calc. % total fatty acids plus unsaponifiable matter (crude fatty acids). Subtract value for unsaponifiable matter, 28.035, to obtain total fatty acids.

#### 28.035

#### Unsaponifiable Matter

Starting with freshly saponified sample, 28.033, ext (without acidification) as in 28.034. Cool r-b flask and transfer hexane soln to 250 mL separator, rinsing gently with 10 mL hexane.

Det. unsaponifiable matter as in 28.081, par. 1, beginning "Shake vigorously, . . ." but use hexane instead of ether.

#### Soluble and Insoluble Volatile Acids (Reichert-Meissl and Polenske Values) (70)—Official Final Action

#### 28.036

#### Reagents

- Sodium hydroxide soln.*—(1+1). Prep. as in 50.033(b).
- Glycerol-soda soln.*—Add 20 mL 1 + 1 NaOH soln to 180 mL pure glycerol.
- Silicon carbide.*—Grit No. 6, Carborundum Co.

#### 28.037

#### Determination

Accurately weigh  $5 \pm 0.1$  g sample into clean, dry 300 mL r-b flask. Add 20 mL glycerol-soda soln and heat with swirling over flame or asbestos-covered hot plate until completely saponified, as shown by mixt. becoming perfectly clear. No oil should remain on surface; walls of flask are wet by soln. Let flask cool to ca 100° (ca 5 min) and dissolve contents in  $135 \pm 1$  mL recently boiled  $H_2O$  with min. loss of  $H_2O$  vapor. (135 mL  $H_2O$  is conveniently measured from 125 mL erlenmeyer previously calibrated to deliver  $134.6 \pm 1.0$  g  $H_2O$  at 25°.) Add 6 mL  $H_2SO_4$  (1+4) and 15 pieces of SiC. Distil, using app. with dimensions given in Fig. 28:03. (Adapter may be used for distg into 110 mL vol. flask.) Rest flask on piece of asbestos board with center hole 5 cm diam., and regulate flame so as to collect 110 mL distillate in  $30 \pm 2$  min (measure time from passage of first drop of distillate from condenser to receiving flask), letting distillate drip into receiving flask at temp. of ca 20°.

When 110 mL has distd, substitute 25 mL graduate for receiving flask, remove flame, and disconnect distn head from condenser. Mix without violent shaking, immerse flask contg distillate almost completely in 15°  $H_2O$  15 min, filter thru dry 9 cm moderately retentive paper (S&S 589 White Ribbon is satisfactory), and titr. 100 mL filtrate with 0.1N NaOH, 50.034–50.035, using phthln. Soln should remain pink 2–3 min. Reichert-Meissl value is mL 0.1N NaOH used, corrected for titrn of blank detn,  $\times 1.1$ , calcd to 5.00 g sample.

Remove remainder of sol. acids from insol. acids on filter by washing with three 15 mL portions 15°  $H_2O$ , each previously passed thru condenser, 25 mL graduate, and 110 mL receiving flask. Dissolve insol. acids by passing three 15 mL portions neut. alcohol thru filter paper, each portion having previously passed thru condenser, 25 mL graduate, and 110 mL receiving flask. Titr. combined alc. washings with 0.1N NaOH, using phthln. Polenske value is mL 0.1N NaOH required for titrn, corrected for titrn obtained in blank detn, and calcd to 5.00 g sample.

*Note:* Unless these directions are followed in every detail, reproducible results cannot be obtained.

*Chromatographic tube.*—Fuse 15 cm section of 38 mm od tubing to 20 cm of 22 mm tubing, which in turn is fused to 5 cm of 7 mm tubing, with drip tip.

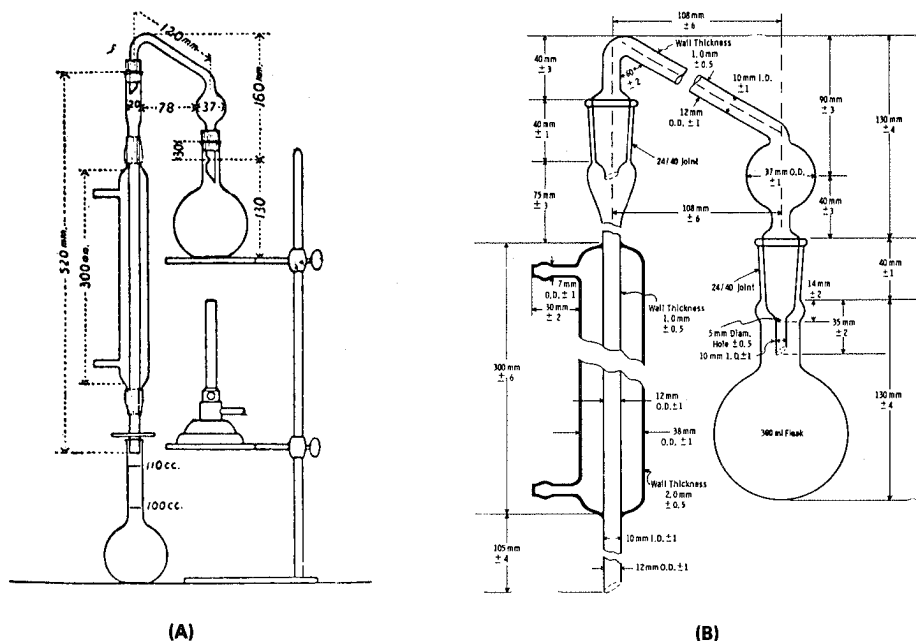

FIG. 28:03—Apparatus for determining Reichert-Meissl and Polenske values; (A) with rubber stoppers, (B) with glass joints

## 28.039

### Reagents

(a) *Silicic acid*.—Mallinckrodt Chemical Works No. 2847. Heat in shallow pan or evapg dish 18 hr at 175°. Store in desiccator or tightly sealed container.

(b) *Bromocresol green-glycol soln.*—Dissolve 700 mg bromocresol green in 700 mL ethylene glycol by warming on steam bath. Cool, and add ca 200 mL H<sub>2</sub>O. Prep. 0.1N NH<sub>4</sub>OH by dilg ca 6.6 mL NH<sub>4</sub>OH to 1 L with H<sub>2</sub>O. Add 40 mL of this soln to indicator soln and addnl H<sub>2</sub>O to make 1 L. Store this ink-blue soln in stoppered bottle.

(c) *Packing material.*—Mix H<sub>2</sub>SiO<sub>3</sub>, (a), in ratio of 100 g to ca 95 mL bromocresol green-glycol soln, (b), until homogeneous olive-green powder is obtained. Small batches may be mixed in mortar; larger batches, in mech. mixer. Prepd packing material may be stored in tightly stoppered container several months.

(d) *Hexane-butanol mixture.*—Add 1 vol. *n*-BuOH to 100 mL vols *n*-hexane (com. grade; Phillips Chemical Co., or equiv.).

(e) *Isopropanol-KOH soln.*—Dissolve 25 g KOH pellets in 400 mL isopropanol by warming and swirling on steam bath. Decant supernate alc. soln from the small amt of aq. soln clinging to bottom of flask. Cool and decant supernate isopropanol-KOH soln, which contains ca 50 mg KOH/mL. Store in refrigerator.

(f) *Potassium hydroxide soln.*—Approx. 0.05N. Dil. 60 mL isopropanol-KOH soln, (e), with 440 mL isopropanol and 500 mL MeOH. Store in amber or "Lifetime Red" Pyrex bottle.

(g) *Thymol blue soln.*—Dissolve 300 mg thymol blue in 25 mL 0.05N alc. KOH soln, (f), and add 75 mL isopropanol.

## 28.040

### Preparation of Fatty Acid Solution

(a) *Saponification.*—Transfer 0.5–0.7 g well mixed, melted fat to 20 × 150 mm test tube with lip, and add 5 mL isopropanol-KOH soln, (e), and boiling chip. Place tube to depth of 5 cm in boiling H<sub>2</sub>O bath 20 min to saponify fat, and evap. isopropanol, leaving solid soap. Stopper, and analyze within 48 hr.

(b) *Determination of quantity of acid required to hydrolyze soap.*—Add 5 mL isopropanol-KOH soln, (e), to 10 mL H<sub>2</sub>O and 2 drops thymol blue soln, (g), in small beaker or flask. Add H<sub>2</sub>SO<sub>4</sub>,

(2+1) dropwise, with const stirring, until initial blue color turns to yellow, orange, and finally red. This vol. H<sub>2</sub>SO<sub>4</sub>, measured with same dropper, is subsequently used to hydrolyze the soap. (If top of chromatgc column turns blue on addn of fatty acid soln, use of more H<sub>2</sub>SO<sub>4</sub> to hydrolyze soap is indicated; top of chromatgc column should be yellow.)

(c) *Hydrolysis of soap and extraction of fatty acids.*—Add to soap, while cooling tube in cold H<sub>2</sub>O, number of drops H<sub>2</sub>SO<sub>4</sub>, (2+1) indicated in (b). Break up lumps in bottom of tube with glass stirring rod. After mass in tube is thoroly mixed, yellow mixt. of fatty acids clinging to viscous aq. layer of K<sub>2</sub>SO<sub>4</sub> should be obtained. Add 10 mL hexane-BuOH soln to tube and thoroly mix with glass rod. Aq. phase should cling to white ppt of K<sub>2</sub>SO<sub>4</sub>, allowing easy decantation of solv. soln of fatty acids. This soln of acids is ready for chromatgy.

## 28.041

### Preparation of Chromatographic Column

Overlay 35 g packing material with hexane-BuOH soln in mortar. Mix with pestle to form slurry. Place small glass wool plug loosely in constricted end of column and gently tamp into place with glass rod. Place finger over constricted end of column and add hexane-BuOH soln until reservoir is half full. Using teaspoon, underlay prepd slurry beneath solv. Jiggle spoon up and down along side of reservoir, and let flocculent slurry settle to bottom of column.

After adding all packing material, remove finger and let solv. flow out and packing material settle. Apply 5–10 lb (34.5–68.9 kPa) air pressure to top of column to speed up flow of solv. and facilitate uniform packing of slurry. Release pressure just before last portion of solv. sinks into column. If column looks uniformly packed, it is ready for use; if not, add more hexane-BuOH soln to reservoir and again apply pressure as before. Prepd column should have flow rate of ca 3.5 mL/min without use of pressure. If flow rate is <3 mL/min, add more bromocresol green-glycol soln to packing material, and remix. If flow rate is >4 mL/min, add more H<sub>2</sub>SiO<sub>3</sub> to packing material, and remix. Hexane-BuOH soln, recovered during prepn of column, may be used subsequently to prep. other columns or for chromatgy.

**28.042****Chromatography of Fatty Acids**

Decant solv. soln of fatty acids onto top of packed column and immediately start collecting eluate in 250 mL erlenmeyer. As soon as fatty acid soln completely settles into packing, wash down inside of reservoir with three 5 mL portions hexane-BuOH soln. Let each washing sink into packing before refilling reservoir. Yellow band should always be observed at very top of column; this band contains inorg. acids ( $\text{H}_2\text{SO}_4$  and acid sulfate) and will not move.

If sample contains butterfat, second distinct yellow band due to butyric acid appears and slowly migrates down column, breaking away from top band. Long-chain fatty acids,  $\geq \text{C}_6$ , pass rapidly thru column and do not form yellow bands. Eluate vol. between elution of last traces of long-chain acids and first traces of butyric acid will be 20–30 mL. When lower edge of yellow butyric acid zone is 1 cm from lower end of chromatgc column, change fraction collector. First fraction contains long-chain acids and is usually  $100 \pm 10$  mL. Next 120 mL fraction contains butyric acid.

**28.043****Titration of Fatty Acid Fractions**

Add 1 drop thymol blue soln for each 10 mL eluate being titrd. Titr. each fraction to first permanent appearance of purple-blue end point, using ca 0.05N KOH, (f), dispensed from 50 mL buret for first fraction and from 5 mL buret, graduated in 0.01 mL, for second fraction. End point for each fraction is sharp but is subject to fading because of  $\text{CO}_2$  absorption. The  $\text{CO}_2$  effect is negligible if titrn is conducted rapidly with little agitation. If necessary, titrn may be carried out in  $\text{CO}_2$ -free atm. which tends to make titrn values more reproducible. (Pass air thru 20% aq. KOH soln, then thru  $\text{H}_2\text{O}$ , and finally into titrn flask.)

Blank corrections are not required. Alkali added to thymol blue soln takes care of blank.

Express butyric acid titrn as % of sum of the 2 titrns, calcd to nearest 0.1%. *Example:* Long-chain acid titrn = 26.1 mL; butyric acid titrn = 2.83 mL; sum = 28.93. Mole % butyric acid =  $2.83 \times 100/28.9 = 9.8$ .

★ **Saturated and Unsaturated Fatty Acids** ★**28.044 Lead Salt-Ether Method (12)—Official Final Action**

See 28.039, 11th ed.

**Polyunsaturated Acids (13)—Official Final Action****American Oil Chemists' Society Method****28.045****Principle**

Natural conjugated constituents are detd by measuring UV absorption at specified wavelengths in purified solv. Nonconjugated polyunsatd constituents are partially conjugated by heating in KOH-glycol soln, and absorptions of conjugated constituents are redetd. The % conjugated diene, triene, tetraene, and pentaene acids are calcd from predetd *a* by simultaneous equations.

Method is applicable to detn of polyunsatd acids, dienolic thru pentaenoic, in animal and vegetable fats contg only natural or *cis* isomers, only small amts of preformed conjugated material, and only small amts of pigments whose absorption may undergo considerable change during the alkali isomerization. Method is not applicable, or is applicable only with specific precautions, to hydrogenated oils or other fats contg *trans* isomers of unsatd fatty acids, to fish oils or similar fats contg acids more highly

unsatd than pentaenoic, to crude oils or samples contg pigments whose absorption undergoes changes during alkali isomerization, or to fats and oils contg large amts of preformed conjugated fatty acids.

**28.046****Apparatus**

(a) *Isomerization apparatus.*—(See Fig. 28:04.) (1) *Constant temperature bath.*— $180 \pm 1^\circ$ . Capacity sufficient to immerse  $25 \times 250$  mm Pyrex test tubes to depth of 114 mm (4.5"). (Westinghouse, or equiv. household deepfat fryer has been found satisfactory.) For bath liq. use Fisher Scientific Co. No. B-219 bath wax or DC 550 Fluid, Dow Corning Corp. Place bath in insulated box with insulated cover having holes for stirrer and cork supports for test tubes.

(2) *Test tubes.*—Pyrex, lipped,  $25 \times 250$  mm.

(3) *Distributing heads.*—To fit test tubes snugly. Tubing in center of head has both ends open and 2 small holes 25 and 38 mm, resp., from bottom. (See Fig. 28:05, right.)

(4) *Manifold.*—With 10 outlets, each connected to 50 mm long capillary tube, 1 mm bore. Cap unused outlets. (See Fig. 28:05, left.)

(5) *Nitrogen manometer.*—Construct from 6 mm od tubing bent in shape of U-tube, ht ca 380 mm, width ca 30 mm. Fill manometer ca half full with  $\text{H}_2\text{O}$  contg 1 drop Me orange and 1 drop  $\text{H}_2\text{SO}_4$ . To adjust flow of N, attach ca 90 cm rubber tubing to one of N outlets on distributing head. Fill 100 mL graduate with  $\text{H}_2\text{O}$  and invert in container of  $\text{H}_2\text{O}$ . Insert end of rubber tubing under graduate. Turn on N supply and measure rate of displacement of  $\text{H}_2\text{O}$  in graduate. Rate of flow should be 50–100 mL/min. Mark level of liq. in manometer at this flow rate.

(b) *Spectrophotometer.*—Covering range of 220–360 nm with wavelength scale readable to 0.1 nm. Beckman Model DU is satisfactory. Adjust H lamp with no cell in beam so meter balances at lowest possible wavelength (usually  $\leq 211$  nm). Slit widths are critical for absorption measurements at 262, 268, and 274 nm where, at final balancing, adjustments must be 0.8–0.9 mm.

(c) *Absorption cells.*—Quartz, matched pairs in lengths  $1.000 \pm 0.005$  cm. When filled with  $\text{H}_2\text{O}$  or isooctane, must match within 0.01 A unit.

**28.047****Reagents**

(a) *Methanol, absolute.*—Check A of 1 cm layer of MeOH against  $\text{H}_2\text{O}$  at 220 nm and thru range of wavelengths used in

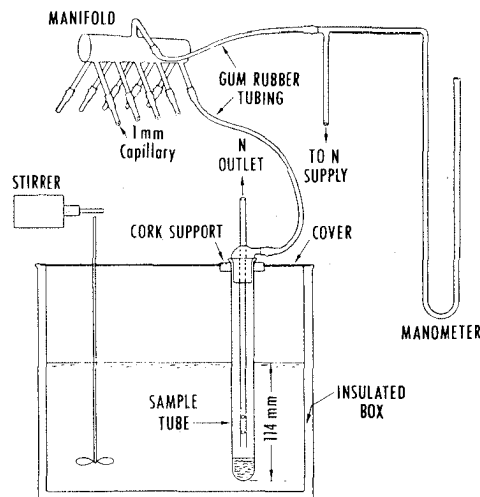

FIG. 28:04—Constant temperature bath and accessories

★ Surplus method—see inside front cover.

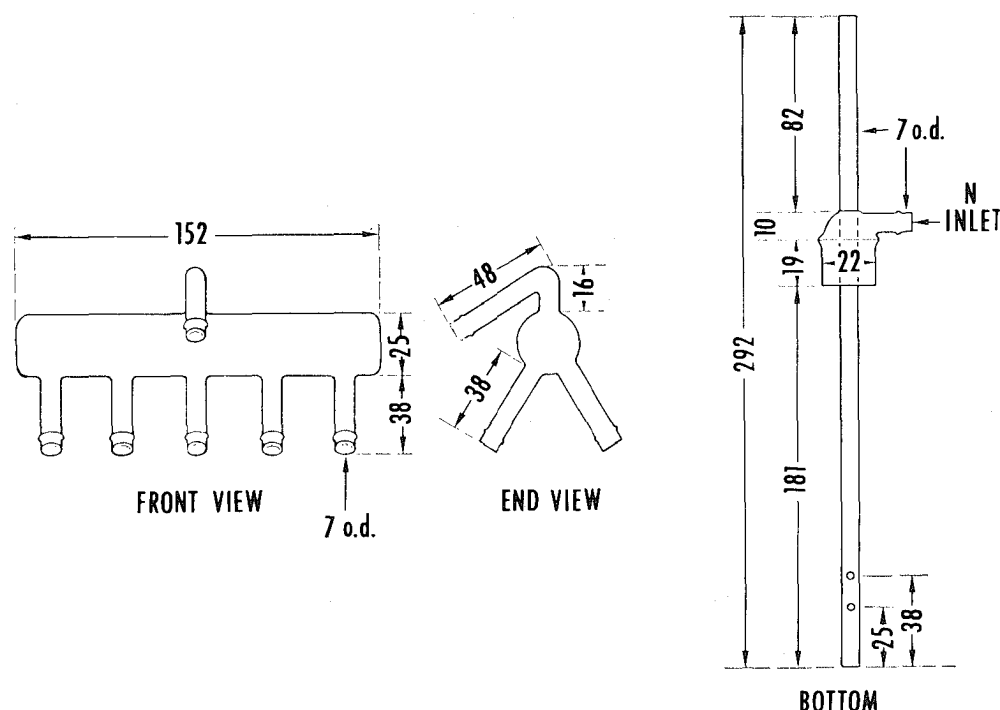

FIG. 28.05—Right, distribution heads. Left, manifold. All dimensions are in mm

analysis. *A* at 220 nm must be  $<0.4$  and curve should be smooth in range 262–322 nm. Otherwise purify as follows, and recheck *A*:

Place 2 L MeOH from new drum or glass bottles into 3 L double-neck  $\frac{1}{2}$  distg flask; add 10 g KOH and 25 g Zn dust. Stopper one outlet and place reflux condenser in other, and reflux on steam bath 3 hr. Remove from steam bath; replace reflux tube with distg trap, 75° connecting tube, and condenser. Place flask in  $H_2O$  bath or elec. heating mantle and distil, collecting distillate in 2 L erlenmeyer. Store in g-s bottle. Absolute alcohol is satisfactory if of comparable purity (as obtained or purified).

(b) *Isooctane (2,2,4-trimethylpentane)*.—NBS certified grade or spectral grade, Phillips Chemical Co. Hexane or cyclohexane is satisfactory if *A* requirements are met. Purify as follows: Place ca 9 cm glass wool above stopcock at lower end of 80  $\times$  4.5 cm filter tube. Add ca 30 cm silica gel (Grade 12, 28–200 mesh, Fisher No. S-157, or equiv.). Pour isooctane slowly into tube, filling ca  $\frac{3}{4}$  full. Insert cork stopper covered with Al foil loosely in top of tube and let isooctane filter thru silica gel, collecting in 2 L erlenmeyer. Renew silica gel as often as necessary to yield isooctane conforming to *A* limit. Check *A* of 1 cm layer of the isooctane against  $H_2O$  thru range of wavelengths used in analysis. *A* compared with  $H_2O$  set at 0 must be  $\leq 0.070$  at all wavelengths, and the resultant *A* versus wavelength curve must be smooth. Otherwise refilter and recheck *A*.

(c) *Potassium hydroxide-glycol soln.*—6.6% KOH for 25 min isomerization. Weigh ca 750 g ethylene glycol into 1 L r-b Pyrex flask. Close with hollow stopper contg short outlet tube and inlet tube reaching to bottom of flask. Connect inlet tube to O-free  $N$  supply ( $<0.01\%$  O) and bubble  $N$  thru liq. during all stages of prepn to exclude all air and to agitate liq. slightly. Place in oil bath at 100–150°; raise bath temp. to 190° and hold 10 min to dry glycol. Remove bath and let bath temp. drop to 120°. Slowly and carefully add 60 g 85% KOH, keeping soln under  $N$ . Return to oil bath; reheat bath to 190° and hold at this temp. 10 min. Remove from bath, and cool. Remove hollow

stopper and close with solid stopper. Store in refrigerator at ca 4° (40°F) under  $N$ .

Check KOH content by adding 10.00 g KOH-glycol soln to ca 90 mL MeOH, neutrd with 1*N* HCl to phthln end point. Titr. with stdzd 1*N* HCl until pink just disappears. % KOH =  $mL \times \text{normality} \times 5.61/\text{wt soln}$ . If % KOH is not 6.5–6.6, dry some glycol by heating under  $N$  at 190° as above, and adjust to 6.6% KOH.

(d) *Potassium hydroxide-glycol soln.*—21% KOH for 15 min isomerization. Prep. as in (c), except use 210 g 85% KOH. Titr., and adjust to 21 $\pm$ 0.1% KOH, if necessary.

(e) *Nitrogen gas.*—Pre-purified grade,  $<0.01\%$  O.

#### 28.048

#### Preparation of Sample

Melt sample carefully on steam bath, stir thoroly, and filter if not clear.

#### 28.049

#### Determination

(The 6.6% KOH method is preferred when samples contain only linoleic and linolenic acids; the 21% KOH method is preferred when samples contain linoleic, linolenic, and arachidonic acids. When pentaenoic acids are present, 21% KOH method must be used.)

(a) *For conjugated polyunsaturated acids.*—Into 1 mL Pyrex cup (diam. 14 mm, ht 10 mm) weigh enough sample to give *A* reading of  $\geq 0.2$  (ca 200 mg). Drop cup into 75 mL isooctane in 150 mL beaker, and rotate beaker to dissolve sample, warming if necessary. Cool to room temp., transfer to 100 mL g-s vol. flask, dil. to vol. with solv., and mix thoroly. Measure *A* in UV region against matched cell contg solv., dilg soln (and/or using other cell lengths if necessary so that observed *A* is 0.2–0.8). Also take readings on both sides of specified wavelengths to det. that max. is present. Component is considered absent if max. is not found in characteristic region and no further calcns are made in this region. Measure at: Dienoic, 233 nm; trienoic, 262, 268, 274 nm; tetraenoic, 308, 315, 322 nm; pentaenoic, 346 nm.

(b) *For nonconjugated polyunsaturated acids, 6.6% KOH, 25 min isomerization.*—Weigh 100 mg (to nearest 0.5 mg) sample into 1 mL Pyrex glass cup. Weigh  $11.0 \pm 0.1$  g of the 6.6% KOH-glycol soln into  $25 \times 250$  mm Pyrex test tube. Conduct  $\geq 2$  blank detns with sample. Cover tube with distributing head and connect to a capillary tube on manifold. Adjust flow of N to permit  $\geq 50$ –100 mL N to pass thru tube/min. Let N sweep thru tube 1 min to remove air; then immerse to depth of 114 mm in bath at  $180 \pm 1^\circ$ . Check temp. frequently and stdze thermometer at frequent intervals.

After 20 min remove distributing head and drop 1 mL cup contg weighed sample into tube, note exact time, and replace head. Drop clean 1 mL cup into blanks. Keeping distributing head in place, remove tube from bath, swirl vigorously few sec, and return to bath; after 1 min, examine soln. If clear, return to bath; if not clear, indicating incomplete saponification, swirl tube 2–3 times and return to bath. At 1 min intervals, repeat swirling until saponification is complete. Keep bath temp. at  $180 \pm 1^\circ$ .

Exactly 25 min after dropping sample into tube, remove from bath, wipe clean, and place in 3 L beaker to cool, continuing to pass N over soln. Cold H<sub>2</sub>O bath may also be used. After cooling, remove head, and wash lower tubing with 20 mL purified MeOH, collecting washings in test tube. Wash with MeOH from beaker; do not use wash bottle.

Insert glass stirring rod 30 cm long with curved end at bottom into test tube and move cup up and down to mix soln. Transfer soln to 100 mL g-s vol. flask, dil. to vol. with purified MeOH, and mix thoroly. Measure *A* as in (a), using KOH-glycol blank as ref. If diln of sample soln is required, make similar dilns of blank. If blanks do not check, repeat tests, increasing flow of N.

(c) *For nonconjugated polyunsaturated acids, 21% KOH, 15 min isomerization.*—Proceed as in (b), except use 80 mg sample and  $21 \pm 0.1\%$  KOH-glycol soln, and isomerize exactly 15 min.

## 28.050

### Spectrophotometric Readings

If polyunsatd fatty acid constituent is known to be absent, or its absence is confirmed during analysis (no max. detected at its anal. wavelength), no spectrophtric reading is required in region of its absorption and no *a* at that region need be included in equations. For example, cottonseed oil is known to contain no polyunsatd constituents more highly unsatd than dienoic (linoleic acid). Hence, in analysis of this oil, measurements are required only at 233 nm, and equation to calc. linoleic acid content requires *a* only at this wavelength.

Correction for background absorption is used only when measuring very small traces of fatty acids. When fatty acid is present in more than trace, background corrections are not required and their use may lead to erroneous results. When *a* of any polyunsatd constituent after isomerization, at its analytical wavelength, is  $> 1.0$ , no background correction should be made. No background corrections are to be made after isomerization with 21% KOH.

## 28.051

### Calculations

(a) *Absorptivity for conjugated constituents.*—Calc. *a* for each wavelength recorded in detn, **28.049(a)**, using subscripts, 233, 268, 315, 346, to designate each individual *a*.

Absorptivity,  $a = A/bc$ , where *A* = observed absorbance, *b* = cell length in cm, and *c* = g sample/L final diln used for *A* measurement.

In following equations, subscripts 2, 3, 4, and 5 refer to diene, triene, tetraene, and pentaene constituents, resp.

Absorptivity at 233 nm corrected for absorption by acid or ester groups =  $a_2 = a_{233} - a_0$ , where  $a_0 = 0.07$  for esters and 0.03 for soaps and fatty acids.

Absorptivity at 268 nm corrected for background absorption =  $a_3 = 2.8 [a_{268} - \frac{1}{2}(a_{262} + a_{274})]$ .

Absorptivity at 315 nm corrected for background absorption =  $a_4 = 2.5 [a_{315} - \frac{1}{2}(a_{308} + a_{322})]$ .

Absorptivity at 346 nm =  $a_5 = a_{346}$ .

(b) *Conjugated acids.*—If quantities within brackets of  $a_3$  or  $a_4$  are 0 or neg., no characteristic absorption maxima are present and corresponding constituent is reported as absent. As preformed constituents are usually present in small amts, background absorption corrections are usually required. If large amts of preformed constituents are present, this method is not applicable. However, no background corrections are to be applied to readings in pentaenoic region, 346 nm.

% Conjugated diene =  $C_2 = 0.91a_2$ .

% Conjugated triene =  $C_3 = 0.47a_3$ .

% Conjugated tetraene =  $C_4 = 0.45a_4$ .

% Conjugated pentaene =  $C_5 = 0.39a_5$ .

(c) *Absorptivities for nonconjugated constituents, 6.6% KOH, 25 min isomerization.*—Calc. *a'* for each wavelength in detn, (b),  $a' = A/bc$ .

Absorptivity at 233 nm corrected for conjugated diene acids originally present =  $a'_2 = a'_{233} - a_2 - 0.03$ .

Absorptivity at 268 nm corrected for background absorption and for undestroyed conjugated triene =  $a'_3 = 4.03[a'_{268} - \frac{1}{2}(a'_{262} + a'_{274})] - a_3$ .

Absorptivity at 315 nm corrected for background absorption and for undestroyed conjugated tetraene =  $a'_4 = 2.06[a'_{315} - \frac{1}{2}(a'_{308} + a'_{322})] - a_4$ .

(d) *Nonconjugated acids, 6.6% KOH, 25 min isomerization.*—(1) Without background corrections:

% Linoleic acid =  $X = 1.086a'_2 - 1.324(a'_{268} - a_{268}) + 0.40(a'_{315} - a_{315})$ .

% Linolenic acid =  $Y = 1.980(a'_{268} - a_{268}) - 4.92(a'_{315} - a_{315})$ .

% Arachidonic acid =  $Z = 4.69(a'_{315} - a_{315})$ .

(2) When background corrections are required:

% Linoleic acid =  $X = 1.086a'_2 - 1.324a'_3 + 0.40a'_4$ .

% Linolenic acid =  $Y = 1.980a'_3 - 4.92a'_4$ .

% Arachidonic acid =  $Z = 4.69a'_4$ .

(e) *Absorptivities for nonconjugated constituents, 21% KOH, 15 min isomerization.*—Calc. *a'* for each wavelength 233, 268, 315, and 346 nm. (If no max. is found, report component as 0 without further measurement or calcn.)

Absorptivity at 233 nm =  $a'_2 = a'_{233} - a_2$ .

Absorptivity at 268 nm =  $a'_3 = a'_{268} - a_{268}$ .

Absorptivity at 315 nm =  $a'_4 = a'_{315} - a_{315}$ .

Absorptivity at 346 nm =  $a'_5 = a'_{346} - a_{346}$ .

(f) *Nonconjugated acids, 21% KOH, 15 min isomerization.*—(Spectrophtric method will not differentiate between acids with same number of double bonds but different chain length, e.g., between C<sub>20</sub> and C<sub>22</sub> pentaenes. First 2 sets of equations below are for samples contg C<sub>20</sub> pentaene acid and for samples contg C<sub>22</sub> pentaene acid, resp. If chain length is unknown, assume that these pentaene acids are present in equal amts, and apply third set of equations.)

(1) *Samples contg C<sub>20</sub> pentaene acid:*

% Linoleic acid =  $X = 1.09a'_2 - 0.57a'_3 - 0.26a'_4 + 0.002a'_5$ .

% Linolenic acid =  $Y = 1.10a'_3 - 0.88a'_4 + 0.31a'_5$ .

% Arachidonic acid =  $Z = 1.65a'_4 - 1.55a'_5$ .

% Pentaenoic acids =  $P = 1.14a'_5$ .

(2) *Samples contg C<sub>22</sub> pentaene acid:*

% Linoleic acid =  $X = 1.09a'_2 - 0.57a'_3 - 0.26a'_4 - 0.12a'_5$ .

% Linolenic acid =  $Y = 1.10a'_3 - 0.88a'_4 - 0.02a'_5$ .

% Arachidonic acid =  $Z = 1.65a'_4 - 1.86a'_5$ .

% Pentaenoic acids =  $P = 1.98a'_5$ .

(3) *Samples contg pentaene acids of unknown chain length (calcd as 50% C<sub>20</sub>–50% C<sub>22</sub> pentaenoic acids):*

% Linoleic acid =  $X = 1.09a'_2 - 0.57a'_3 - 0.26a'_4 - 0.03a'_5$ .

% Linolenic acid =  $Y = 1.10a'_3 - 0.88a'_4 + 0.19a'_5$ .

% Arachidonic acid =  $Z = 1.65a'_4 - 1.67a'_5$ .

% Pentaenoic acids =  $P = 1.45a'_5$ .

(g) *Total composition:*

% Total conjugated polyunsatd acids =  $C_2 + C_3 + C_4 + C_5$ .

% Total nonconjugated polyunsatd acids =  $X + Y + Z + P$ .

% Oleic acid = {I value (Wijs) of sample – [1.811 (C<sub>2</sub> + X) + 2.737(C<sub>3</sub> + Y) + 3.337(C<sub>4</sub> + Z) + 4.014\* (C<sub>5</sub> + P)]}/0.899.

% Satd acids = % total fatty acid – (% oleic acid + % conjugated acid + % nonconjugated acid).

(% total fatty acid of most naturally occurring oils is 95.6. To calc. to fatty acid basis, multiply the % value by 100/% total fatty acid.)

#### Preparation of Methyl Esters

#### 28.052 ★ Esterification in Presence of Sulfuric Acid ★ Official First Action

See 26.052, 10th ed.

#### Boron Trifluoride Method (14)—Official First Action AOAC-IUPAC Method

#### 28.053

#### Principle

Glycerides and phospholipids are saponified, and fatty acids are liberated and esterified in presence of BF<sub>3</sub> catalyst for further analysis by IR, 28.079, or GLC, 28.062.

Method is applicable to common animal and vegetable oils and fats, and fatty acids. Unsaponifiables are not removed, and if present in large amts, may interfere with subsequent analyses.

Method is not suitable for prepn of methyl esters of fatty acids contg major amts of epoxy, hydroperoxy, aldehyde, ketone, cyclopropyl, and cyclopropenyl groups, and conjugated polyunsatd and acetylenic compds because of partial or complete destruction of these groups.

#### 28.054

#### Apparatus

(a) *Reaction flasks.*—50 and 125 mL flasks with outer  $\mathbb{F}$  joints.

(b) *Condenser.*—Water-cooled, reflux, with 20–30 cm jacket and  $\mathbb{F}$  inner joint.

#### 28.055

#### Reagents

(a) *Boron trifluoride reagent.*—125 g BF<sub>3</sub>/L MeOH. Available com. or prep. as follows: Weigh 2 L flask contg 1 L MeOH. Cool in ice bath and with flask still in bath, bubble BF<sub>3</sub> from cylinder thru glass tube into MeOH until 125 g is absorbed. Work in hood. BF<sub>3</sub> must be flowing thru glass tube before it is placed in and until it is removed from MeOH to prevent liq. from being drawn into cylinder valve system. Gas should not flow so fast that white fumes emerge from flask. Reagent is stable 2 years. (Caution: Remove BF<sub>3</sub> vapors with effective fume removal device. Avoid contact with skin, eyes, and respiratory tract. See 51.010.)

(b) *Methanolic sodium hydroxide soln.*—0.5N. Dissolve 2 g NaOH in 100 mL MeOH contg  $\leq 0.5\%$  H<sub>2</sub>O. White ppt of Na<sub>2</sub>CO<sub>3</sub> forming on long standing may be ignored.

(c) *Heptane.*—Pure, as detd by GLC. If fatty acids contg  $\geq 20$  C atoms are absent in sample, hexane may be substituted.

(d) *Methyl red soln.*—0.1% in 60% alcohol.

(e) *Nitrogen.*—Contg  $< 5$  mg O/kg.

Check new batches of reagents, particularly BF<sub>3</sub>, by prep and chromatographing Me esters of pure oleic acid. If extraneous peaks appear (in C<sub>20</sub>–C<sub>22</sub> region with BF<sub>3</sub>), reject reagent.

#### 28.056

#### Preparation

(Caution: See 51.011 and 51.073.)

(Work in hood. Wash all glassware immediately after use. If fatty acids contg  $> 2$  double bonds are present, remove air from MeOH and flask by passing in stream of N few min. Me esters should be analyzed as soon as possible. If necessary, heptane soln may be kept under N in refrigerator. For prolonged storage, seal in ampule and store in freezer or add equiv. of 0.005% 2,6-di-*tert*-butyl-4-methylphenol (BHT). For IR analysis, solv. removal must be as complete as possible; for GLC, 5–10% soln is suitable.)

Precise weighing is not required. Sample size need be known only to det. size of flask and amts of reagents, according to following table:

Sample mg	Flask mL	0.5N NaOH mL	BF <sub>3</sub> Reagent mL
100–250	50	4	5
250–500	50	6	7
500–750	100	8	9
750–1000	100	10	12

Sample ca 350 mg is preferred for GLC.

(a) *For fats and oils.*—Add sample to flask and then add methanolic NaOH soln and boiling chip. Attach condenser, and reflux until fat globules disappear (usually 5–10 min). Add BF<sub>3</sub> soln from bulb or automatic pipet thru condenser and continue boiling 2 min. Add 2–5 mL heptane thru condenser and boil 1 min longer. Remove heat, then condenser, and add several mL satd NaCl soln. Rotate flask gently several times. Add addnl satd NaCl soln to float heptane soln into neck of flask. Transfer ca 1 mL upper heptane soln into g-s test tube and add small amt anhyd. Na<sub>2</sub>SO<sub>4</sub> to remove H<sub>2</sub>O. If necessary, dil. soln to concn of 5–10% for GLC.

To recover dry esters, transfer aq. and heptane phases to 250 mL separator. Ext with two 50 mL portions pet ether (bp 30–60°) or hexane. Wash combined exts with 20 mL portions H<sub>2</sub>O until acid-free to Me red indicator. Dry over anhyd. Na<sub>2</sub>SO<sub>4</sub>, filter, and evap. solv. under stream of N on steam bath. If sample is  $< 500$  mg, reduce vols of solv. and H<sub>2</sub>O.

More volatile esters may be lost if evapn is prolonged or if stream of N is too vigorous. For IR spectroscopy, terminate evapn as soon as solv. is removed. For GLC, method is applicable to fatty acids with  $\geq 8$  C atoms, if solv. is not completely removed.

(b) *For fatty acids.*—Add fatty acid sample to flask, then add BF<sub>3</sub> soln, and continue as in (a) with 2 min boiling under reflux.

#### Methyl Esters of Fatty Acids

#### AOAC-IUPAC Gas Chromatographic Method (15) Official First Action

#### 28.057

#### Principle

Me esters of fatty acids from animal and vegetable fats having 8–24 C atoms are sep and detd by gas chromatog. Method is not applicable to epoxy, oxidized, or polymerized fatty acids.

\* Corresponding constant for sample contg all C<sub>20</sub> pentaene acids is 4.197; for all C<sub>22</sub> pentaene acids it is 3.841.

★ Surplus method—see inside front cover.

**28.058****Apparatus**

Following conditions are for use with flame ionization detector:

(a) *Gas chromatograph*.—With min. dead space in injection system, which is maintained at 20–50° higher than column temp. Maintain column temp. within  $\pm 1^\circ$  to at least 220°. If programmed heated, dual columns are recommended.

(b) *Columns*.—1–3 m  $\times$  2–4 mm (id) glass or stainless steel (do not use stainless steel with polyunsatd components with  $>3$  double bonds). Use short column when long-chain ( $>20$  C atoms) acids are present.

(c) *Packing*.—Acid-washed and silanized diat. earth, with narrow range (25  $\mu$ m) grain size between 125–250  $\mu$ m (No. 60–120). Av. grain size is inversely related to id and directly related to column length. Coat with 5–20% polyester type polar liq. stationary phase (diethylene glycol polysuccinate, butanediol polysuccinate, ethylene glycol polyadipate, etc.) or other liq. (e.g., cyanosilicones) meeting efficiency and resolution specifications. Nonpolar phase can be used for certain sephs.

Condition column while disconnected from detector at 185° with current of inert gas at 20–60 mL/min for  $\geq 16$  hr and for addnl 2 hr at 195°. Conditioning temp. may vary with specific liq. phase.

(d) *Syringe*.—Max. vol. 10  $\mu$ L, graduated to 0.1  $\mu$ L.

(e) *Recorder*.—0–2.5 or 5.0 mv range,  $<1.5$  sec response rate (time for pen to pass from 0 to 90% following momentary introduction of 100% signal), 25 cm min. paper width, and 25–100 cm/hr paper speed, with attenuator switch to change range. If integrator is used, it must have linear response with adequate sensitivity and satisfactory baseline correction.

If thermal conductivity detector is used, conditions must be modified as follows: Column, 2–4 m  $\times$  4 mm id; support, grain size 150–250  $\mu$ m (No. 60–100); stationary phase, 15–25%; carrier gas, He or H; no auxiliary gas; temps (°): column 180–200, injector 40–60° above that of column; carrier gas flow, 60–80 mL/min; recorder, 0–1 mv range; and amt sample injected, 0.5–2  $\mu$ L. Correction factors must be used.

**28.059****Reagents**

(a) *Carrier gas*.—N, He, Ar dried and contg  $<10$  mg O/kg.

(b) *Other gases*.—H, 99.9+%, free from org. impurities. Air or O, free from org. impurities ( $<2$  ppm hydrocarbons equiv. to CH<sub>4</sub>).

(c) *Reference stds*.—Known mixts of Me esters or Me esters of oil of known composition, preferably similar to that of material to be analyzed.

**28.060****Operating Conditions**

Following variables are involved in selecting appropriate test conditions: length and id of column, temp. of column, carrier gas flow, resolution required, size of sample, and time of analysis. Size of sample should be such that linear response of detector and electrometer is obtained. In general, following conditions will elute Me stearate within ca 15 min at  $\geq 2000$  theoretical plates:

Column id, mm	Concn of Carrier gas flow, stationary phase, mL/min %		Column temp., °C
2	15–25	5	175
3	20–40	10	180
4	40–60	15	185
		20	185

If app. permits, injector should be at ca 200° and detector at temp. above that of column. Flow of H to detector should be ca half that of carrier gas (H flow may be equal to carrier gas flow with N and 2 mm (id) column); flow of O ca 5–10 times that of H.

**28.061****Performance Specifications**

Perform analysis on mixt. of Me stearate and Me oleate in ca equal proportions (e.g., Me esters from cocoa butter). Adjust sample size, column temp., and carrier gas flow so that Me stearate peak is recorded ca 15 min after solv. peak, ca  $\frac{3}{4}$  full scale. Measure base widths in mm of Me stearate ( $w_1$ ) and Me oleate ( $w_2$ ) between points of intersection with baseline of tangents drawn to inflection points of curves. Also measure retention distance in mm ( $S$ ) from start to peak max. for Me stearate and distance in mm between peak max. for Me stearate and Me oleate,  $Y$ . Calc. theoretical plates,  $n$  (efficiency), and resolution,  $R$ :

$$n = 16(S/w_1)^2,$$

$$R = 2Y/(w_1 + w_2).$$

Select conditions to obtain  $n \geq 2000$  and  $R \geq 1.25$ . In addn, linolenic acid (18:3) Me ester should be sepd from arachidic acid (20:0) and gadoleic acid (20:1) esters. Columns will show gradual loss in  $R$  with use; when value becomes  $\leq 1.25$ , replace.

**28.062****Determination**

With app. showing stable baseline, inject 0.1–2  $\mu$ L 5–10% heptane soln of Me esters, **28.053**. If trace components are desired, sample may be increased  $\leq 10\times$ . Pierce septum of inlet port and quickly discharge sample. Withdraw needle and note on chart small peak due to air or solv., marking start ref. point. Adjust sample size so major peak is not attenuated  $>8\times$ , preferably less. Change setting of attenuator as necessary to keep peaks on chart paper. Mark attenuator setting on chart.

For detn of acids  $<C_{12}$ , lower column temp. is needed; for  $>C_{20}$ , higher. Temp. programming is useful in such cases, e.g., with acids  $<C_{12}$ , inject at 100° and raise temp. 4–8°/min to optimum, or program up to a fixed temp. and continue at const temp. until all components are eluted. If app. does not use programmed heating, operate at 2 fixed temps between 100° and 195°.

**28.063****Identification**

Analyze ref. std mixts under same operating conditions as for sample. Measure retention distances ( $S$ ) for known esters. Plot  $\log S$  as function of no. of C atoms of acids. Under isothermal conditions, graphs of straight chain esters of same degree of unsatn should be straight lines, approx. parallel. Identify peaks from sample from these graphs, interpolating if necessary. Avoid conditions which permit "masked peaks," i.e., which are not sufficiently resolved.

Esters appear in order of increasing no. of C atoms and of increasing unsatn for same no. of C atoms.  $C_{16}$  is ahead of  $C_{18}$ , and  $C_{18}$  Me esters appear in order: stearate (18:0), oleate (18:1), linoleate (18:2), and linolenate (18:3).  $C_{20}$  satd ester (arachidic, 20:0) usually appears before 18:3 ester, but may be reversed on some columns, or positions may change with column use.

**28.064****Calculations**

Use method of normalization, which assumes all components of sample are represented on chromatogram, so that sum of areas under peaks represents 100% of constituents (total elution).

If instrument is equipped with integrator, use figures shown. If not, use triangulation: Draw lines for each peak tangent to sides and intersecting baseline. Calc. area of resulting triangle by multiplying ht (corrected for any change in attenuation) by  $\frac{1}{2}$  base. For automatically attenuated peak, obtain peak width by drawing tangents to outer sides of peak (these must be full chart span, and upper  $\frac{2}{3}$  of peak must be used) and intersecting baseline. Calc. area by multiplying ht (corrected for attenuation) by  $\frac{1}{2}$  base.

If significant amts of components with <12 C atoms are absent, calc. % by wt of each component, expressed as Me ester,

$$C_i = G_i \times 100 / \Sigma G_i,$$

where  $G_i$  = area of peak corresponding to component  $i$ , and  $\Sigma G_i$  = sum of areas under all peaks.

In certain cases, e.g., in presence of components with <12 C atoms, large differences in mol. wts, and presence of secondary groups, correction factors must be used to convert peak areas into wt %. Det. correction factors by analyzing known ref. stds of Me esters of composition similar to that of sample under identical operating conditions. For ref. std,

$$\% \text{ by wt component } i = B_i \times 100 / \Sigma B_i,$$

where  $B_i$  = wt of component  $i$  in ref. std, and  $\Sigma B_i$  = total wt of all components in ref. std. Calc. from chromatogram:

$$\% (\text{area/area}) \text{ of component } i = G_i \times 100 / \Sigma G_i,$$

from which calc. correction factor for each component

$$K_i = (B_i / \Sigma B_i) \times (\Sigma C_i / C_i)$$

Det. correction factors relative to palmitic acid,  $K_{16} = 1$ , so that

$$K' = K_i / K_{16}.$$

Then to calc. % of each component (as Me esters), multiply its area by appropriate correction factor, and sum corrected areas:

$$\% \text{ by wt component } i = (K'_i \times G_i) \times 100 / \Sigma (K'_i \times G_i).$$

In certain cases, e.g., when all components are not eluted, use internal std,  $S$ , such as  $C_{15}$  or  $C_{17}$  Me ester, and det. its correction factor. Then,

% by wt of component  $i$  as Me ester

$$= (w_s/w) \times (K'_i/K'_s) \times (G_i/G_s) \times 100,$$

where  $w_s$  = mg internal std and  $w$  = total mg sample, and subscript  $S$  refers to internal std component.

Report results to following significant figures, with 1 figure beyond decimal point in all cases: 3 for >10%, 2 for 1–10%, and 1 for <1%.

## 28.065

### Precision

(a) *Repeatability*.—Two single detns performed on same day by same operator with same app. on same sample for major components (>5%) should not differ by >3% relative, with an absolute value of 1%.

(b) *Reproducibility*.—Two single detns performed in different laboratories for major components should not differ by >10% relative, with an absolute value of 3%.

## Docosenoic Acid

### Gas Chromatographic Method (16)—Official First Action

## 28.066

### Principle

Erucic acid, an isomer of docosenoic acid, is characteristic acid of rapeseed. Oil or fat is converted to Me esters, which are detd by GLC, with Me tetracosanoate as internal std.

## 28.067

### Apparatus

(a) *Gas chromatograph*.—Varian Model 1740-10, Hewlett-Packard 5700 series, or equiv., with flame ionization detector and 0.9 m (3')  $\times$   $\frac{1}{8}$ " od stainless steel column contg 15% diethylene glycol succinate (DEGS) on 80–100 mesh Chromosorb W, acid washed. Operating conditions: temps ( $^{\circ}$ )—injector 250, detector 290, column 190; He carrier gas flow rate adjusted to give retention time of ca 17 min for Me tetracosanoate. Measure peak areas by electronic integrator, disk integrator, or triangulation.

(b) *Transesterification flask*.—125 mL conical flask with  $\$$  24/40 joint and neck elongated and constricted to 8–10 mm id.

## 28.068

### Reagents

(Caution: See 51.011(a), 51.034, 51.061, 51.063, and 51.066.)

(a) *Hexane*.—Distil reagent grade hexane and dry over anhyd.  $\text{Na}_2\text{SO}_4$  before use.

(b) *Methanol, anhydrous*.—Distil with Mg turnings.

(c) *Sodium methoxide soln*.—Approx. 1% in anhyd. MeOH. Clean ca 1 g Na metal in hexane, dry with filter paper, and dissolve in 100 mL anhyd. MeOH in 250 mL conical flask fitted with silica gel drying tube.

(d) *Methyl erucate std soln*.—2 mg/mL hexane. Dissolve 100 mg Me erucate (Applied Science Laboratories, Inc., 99.5%  $C_{22:1}$ ) in hexane in 50 mL vol. flask and dil. to vol. with hexane.

(e) *Methyl tetracosanoate std soln*.—2 mg/mL hexane. Dissolve 100 mg Me tetracosanoate (Sigma Chemical Co., 99%  $C_{24}$ ; No. L 1126) in hexane in 50 mL vol. flask and dil. to vol. with hexane.

## 28.069

### Determination

(a) *Weight response factor for methyl docosenoate*,  $R_{22:1}$ .—Pipet 1, 2, and 3 mL Me erucate std soln into sep. 25 mL conical flasks. Pipet in 3 mL Me tetracosanoate std soln into each flask and hexane to make 8.0 mL total vol. Inject 2  $\mu$ L of each soln into gas chromatograph.

$$R_{22:1} = (W_{22:1}/W_{24}) \times (P_{24}/P_{22:1}),$$

where  $R_{22:1}$  = wt response factor for erucate relative to tetracosanoate;  $W_{22:1}$  = mg docosenoate (erucate);  $W_{24}$  = mg tetracosanoate;  $P_{24}$  = peak area tetracosanoate; and  $P_{22:1}$  = peak area docosenoate.

(b) *Docosenoic acids in fats and oils*.—Accurately weigh ca 50 mg oil into dry transesterification flask, add 3 mL Me tetracosanoate std soln and 10 mL NaOMe soln, and reflux 1 hr. Cool, add 5 mL hexane, swirl, add 7 mL 1N HCl, stopper, and shake vigorously 1 min. Add  $\text{H}_2\text{O}$  until hexane reaches constricted neck and inject 2  $\mu$ L hexane layer into gas chromatograph.

% Docosenoic acids =  $(P_{22:1}/P_{24}) \times (W_{24}/W_{oil}) \times R_{22:1} \times 100$ , where  $W_{oil}$  = mg oil.

## Polymers and Oxidation Products of Heated Vegetable Oils

### 28.070 Gas Chromatographic Method for Non-Elution Materials (17)—Official First Action

Accurately weigh ca 40 mg oil and 10 mg triheptadecanoin internal std (Applied Science Laboratories, Inc., No. 21322) into 50 mL erlenmeyer. For ease of handling, empty entire vial internal std supplied (100 mg) into tared 100 mL vol. flask, weigh accurately, dissolve triglyceride in hexane, and dil. to vol. To avoid vol. changes, immediately transfer 10 mL aliquots to nine 50 mL erlenmeyers and carefully evap. solv. under N stream.

Flasks may be stoppered and stored at 0° if desired. Weigh sample directly into flask after temp. equilibrium. Add 4 mL 0.5*N* alc. NaOH soln and boiling chip, and reflux 10 min with H<sub>2</sub>O condenser. Add 5 mL BF<sub>3</sub>-MeOH, prepd as in 28.056(a), thru condenser and boil 2 min. Add 2–5 mL pet ether (bp 30–60°) and boil 1 min more. Cool mixt. and transfer to 30 mL separator, washing flask several times with total of 10 mL pet ether. Shake 1 min to ext methyl esters into pet ether. Drain methanolic (lower) phase into second separator and ext again with 10 mL pet ether. Combine pet ether exts, and wash with 5 mL portions H<sub>2</sub>O until washings are acid-free when tested with Me red. Dry with anhyd. Na<sub>2</sub>SO<sub>4</sub>, preferably by pouring sample thru narrow glass column contg Na<sub>2</sub>SO<sub>4</sub>; wash column with 5 mL dry pet ether. Evap. solv. under N with aid of steam bath. Because of small vol. of esters, transfer dry esters to 1 mL test tube-shaped vol. flask or cone-shaped vial to facilitate removal with syringe for injection onto GLC column.

Analyze sample with flame ionization detector as in 28.058–28.063. Measure peak areas of chromatogram by either planimeter or electronic integrator.

$$\% \text{ Non-elution material} = \frac{\left[ PA' + \left( \frac{W' + W}{W'} \right) - PA \right] \times 100}{PA' \times \left[ \left( \frac{W' + W}{W'} \right) - 1 \right]}$$

where PA' = peak area of internal std; W' and W = wts internal std and sample, resp.; and PA = total area of chromatogram.

#### *cis, cis*-Methylene Interrupted Polyunsaturated Fatty Acids (18)—Official First Action

##### 28.071

##### Reagents

(a) *Potassium borate buffer*.—1.0*M*, pH 9.0. Dissolve 61.9 g H<sub>3</sub>BO<sub>3</sub> and 25.0 g KOH in ca 800 mL H<sub>2</sub>O by stirring and heating. Cool to room temp. and adjust to pH 9.0 with 1.0*N* HCl or 1.0*N* KOH, as required. Dil. to 1 L with H<sub>2</sub>O and mix.

(b) *Dilute potassium borate buffer*.—0.2*M*, pH 9.0. Dil 200 mL 1.0*M* buffer, (a), to 1 L with H<sub>2</sub>O and mix.

(c) *Lipoxidase solns.*—(1) *Stock soln.*—Dissolve 10 mg lipoxidase, from soybean, 50,000 units/mg (ICN Life Sciences Group, Nutritional Biochemicals Division, or equiv.), in 10 mL ice-cold dil. borate buffer, (b). Refrigerated soln is stable 30 days. (2) *Working soln.*—Mix 2.0 mL stock soln with 8.0 mL ice-cold dil. borate buffer, (b). If large no. of analyses are to be performed, dil. 5.0 mL stock soln to 25 mL with ice-cold dil. borate buffer, (b). (3) *Inactivated soln.*—Pipet 4 mL working enzyme soln, (2), to 10 mL vol. flask and hold 5 min in boiling H<sub>2</sub>O.

(d) *Alcoholic potassium hydroxide soln.*—0.5*N*. Dissolve 1.40 g KOH in alcohol and dil. to 50 mL with alcohol. Prep. fresh daily.

##### 28.072

##### Preparation of Sample

Accurately weigh ca 100 mg vegetable oil and transfer with *n*-hexane into 100 mL vol. flask, which has just been flushed with N. Dil. to vol. with *n*-hexane or acetone. Pipet 1 mL dild soln into 100 mL vol. flask and completely evap. solv. under N.

##### 28.073

##### Determination

Add 1 mL alc. KOH, (d), soln to solv.-free residue in vol. flask. Heat gently on steam bath to dissolve. Flush with N and hold stoppered, in dark, min. of 5 hr to overnight. After saponification is complete, add 20 mL 1.0*M* borate buffer, (a), and 50 mL H<sub>2</sub>O, and mix. Add 1 mL 0.5*N* HCl, dil. to vol. with H<sub>2</sub>O, and mix.

Pipet 3 mL saponified soln into each of four 13 × 100 mm test tubes. To 2 tubes (blanks) add 0.10 mL inactivated enzyme soln,

(c)(3), and mix well. To remaining duplicate tubes, add 0.10 mL working enzyme soln, (c)(2). Mix by shaking vigorously 30 sec immediately after adding enzyme soln, and let all tubes stand exposed to air at room temp. 30 min. Zero spectrophtr at 234 nm with blank tubes and measure *A* of reacted samples.

For sample, calc. g polyunsatd fatty acid (PUFA) as trilinolein/100 g sample =  $W \times DF \times 10^{-4}$ , where  $W = \mu\text{g}$  trilinolein/mL final soln from std curve, and  $DF = \text{diln factor}$ .

##### 28.074

##### Preparation of Standard Curve

Weigh 100 mg *cis, cis*-trilinolein, 99% (NuCheck Prep, PO Box 172, Elysian, MN 56028, or equiv.), transfer quant. to 100 mL vol. flask, and dil. to vol. with *n*-hexane or acetone. Pipet 10 mL aliquot into 100 mL vol. flask and dil. to vol. with same solv. Pipet 2, 4, 6, 8, 10 and 12 mL aliquots into sep. 100 mL vol. flasks, and evap. each to dryness in stream of N. Pipet 1 mL alc. KOH, (d), into each flask, flush with N, and store stoppered in dark 5 hr or overnight.

Add 20 mL 1.0*M* borate buffer, (a), 50 mL H<sub>2</sub>O, and 1 mL 0.5*N* HCl to each, dil. to vol. with H<sub>2</sub>O, and mix. Pipet four 3 mL aliquots of each std soln into test tubes, incubate, and proceed as in detn, beginning "To 2 tubes (blanks) . . ." Plot av. *A* at each level against  $\mu\text{g}$  trilinolein/mL.

Two single detns in 1 laboratory should not differ by >1.6%; 2 single detns performed in 2 laboratories should not differ by >2.2%.

#### Isolated Trans Isomers (19)—Official First Action

##### American Oil Chemists' Society Method

(Applicable to margarines and shortenings contg <5% total conjugates)

##### 28.075

##### Principle

Unsatd constituents of most vegetable fats and oils contain only nonconjugated (isolated) double bonds in *cis* configuration; these may isomerize to *trans* form during extn and processing due to oxidn or partial hydrogenation. Animal and marine fats may naturally contain some *trans* isomers. In long-chain fatty acids, esters, and glycerides, isolated *trans* bonds show absorption at ca 10.3  $\mu\text{m}$  that can be measured with IR spectrophtr. *Cis* double bonds and satd compds do not show this band.

Long-chain fatty acids also show band at ca 10.6  $\mu\text{m}$  (carboxyl). Correction for this band and any background is made by baseline technic. But if isolated *trans* content is small, correction may greatly affect absorption at 10.3  $\mu\text{m}$ . Therefore, long-chain fatty acids contg <15% isolated *trans* isomers must be converted to their Me esters before making IR measurements.

Triglycerides give isolated *trans* values which are ca 2–3% high and Me esters give isolated *trans* values which are ca 1.5–3% low. Factors are applied to correct for these errors.

Do not apply method to samples contg >5% conjugated unsatn (e.g., tung oil), materials contg functional groups which modify absorption of C-H deformation around *trans* bond (e.g., castor oil contg ricinoleic or ricinelaidic acids), mixed glycerides with long- and short-chain moieties (e.g., diacetostearin), or any materials where specific groups may absorb close to 10.3  $\mu\text{m}$ .

##### 28.076

##### Apparatus

*Infrared spectrophotometer and accessories.*—Covering region ca 9–11  $\mu\text{m}$ , wavelength readable to 0.01  $\mu\text{m}$ , holding fixed thickness cells 0.2–2.0 mm with NaCl or KBr windows. Most convenient are split-beam automatic recording instruments such as Perkin-Elmer Models 21, 221, 567, 621, Beckman Models IR-18A, IR-20A or their successors. All instruments must be checked

for accuracy of wavelength and photometric scales by manufacturer's instructions. Absorptivities of stds (reagents **28.077(b)**) must be established for each instrument, and rechecked periodically. With split-beam instruments, cells filled with CS<sub>2</sub> solv. must balance to 0.01 A. With null type instruments, matched pairs of cells must balance to this figure. Chart paper must be linear in either wavelength or wave no. (depending upon instrument) and calibrated in either *T* or *A*.

**28.077****Reagents**

(a) *Carbon disulfide*.—Dry, ACS grade. Use with adequate ventilation.

(b) *Primary stds*.—Elaidic acid, Me elaidate, and trielaidin, highest possible purity, >99% (Nu-Chek Prep, Inc., PO Box 172, Elysian, MN 56028).

**28.078****Preparation of Samples and Standards**

Melt solid fats on steam bath and mix; filter if cloudy. If *dild* sample is cloudy due to H<sub>2</sub>O, add little anhyd. Na<sub>2</sub>SO<sub>4</sub> to melted sample, mix, and let settle before taking portion for analysis.

Accurately weigh ( $\pm 0.2$  mg) ca 0.2000 g std or sample into 10 mL vol. flask, dil. to vol. with CS<sub>2</sub>, and mix thoroly. *T* at *trans* absorption max. should be 20–70%; if not, use different sample wt or cell thickness.

**28.079****Infrared Determination**

Fill cell with CS<sub>2</sub> solv. and matching cell with prepd sample or std soln, **28.078**. Use hypodermic syringe with blunted needle, and with cell upright, inject from bottom so bubbles pass up thru cell. Measure *T* or *A* from 9 to 11  $\mu$ m.

(Programming of instruments depends upon type, but once basic curve for primary std is derived, all samples must be read on same instrument with controls at identical positions. Proper techniques of slit width, scanning speed, etc., must be used (see "Recommended Practices for General Techniques of Infrared Quantitative Analysis," ASTM, 1916 Race St, Philadelphia, PA 19103). If instrument requires adjustment or replacements (glower, detector, etc.) and exact settings cannot be duplicated, calibration curve of std *must* be rerun and new values used in calcsns.)

**28.080****Calculations**

*Acids, methyl esters, and triglycerides*.—Compare curve of sample (acid, ester, triglyceride) with its appropriate std, **28.077(b)**. Note *A* at 10.36  $\mu$ m peak or convert *T* at this point to *A*, and calc. *a*. On charts, draw baseline from 10.10 to 10.65  $\mu$ m for acids, from 10.02 to 10.59  $\mu$ m for Me esters, or from 10.05 to 10.67  $\mu$ m for triglycerides. For charts registering *T*, draw vertical line at peak (ca 10.3  $\mu$ m) connecting 0 line of chart, *x*; peak, *b*; and baseline, *c*. Fractional *T* =  $xb/x_c$ . Convert this value to *A* and then to background-corrected *a* as below. For charts registering *A*, subtract *A* at baseline from *A* at peak to obtain *A* of sample.

Absorptivity,  $a = A/bc$ , where *A* = corrected absorbance, *b* = cell thickness in cm, and *c* = concn of soln (g/L).

% *Trans* as elaidic acid, Me elaidate, or trielaidin = [*a* (sample, background corrected)/*a* (appropriate std, background corrected)]  $\times$  100.

*Corrected trans values*.—Triglycerides with 0 or low *trans* content read ca 2–3% high; their derived Me esters, **28.056**, read 1.5–3% low or neg. Oils similar to test samples but contg no *trans* isomers may be analyzed to det. suitable correction factors to be used, or following equations may be used to correct approx. for pos. triglyceride or neg. Me ester errors:

For fats and oils contg primarily long-chain fatty acids (peanut oil, cottonseed oil, etc.):

$$\text{Triglycerides, \% trans (corrected)} = (\% \text{ trans (calcd)} - 2.5)/0.975.$$

$$\text{Me esters, \% trans (corrected)} = (\% \text{ trans (calcd)} + 1.5)/1.015.$$

For fats and oils contg large proportions of lower and medium-chain fatty acids (coconut oil, etc.):

$$\text{Triglycerides, \% trans (corrected)} = (\% \text{ trans (calcd)} - 3.0)/0.970.$$

$$\text{Me esters, \% trans (corrected)} = (\% \text{ trans (calcd)} + 3.0)/1.030.$$

Absence of peak at 10.3  $\mu$ m, regardless of baseline *A*, indicates no *trans* isomers in sample.

**28.081 Unsaponifiable Residue (20)—Official Final Action**

(Caution: See **51.011**, **51.039**, and **51.054**.)

Accurately weigh 2–2.5 g fat into saponification flask (200 mL erlenmeyer with  $\frac{1}{4}$  24/40 outer joint is recommended). Add 25 mL alcohol and 1.5 mL KOH soln (3+2). Saponify by boiling, with occasional swirling, on steam bath 30 min under reflux air condenser. (No loss of alcohol should occur during saponification.) Transfer alc. soap soln while still warm to 250 mL separator, using total of 50 mL H<sub>2</sub>O. Rinse saponification flask with 50 mL ether and add ether to separator. Shake vigorously, and let layers sep. and clarify. Drain lower layer and pour ether layer thru top into second separator contg 20 mL H<sub>2</sub>O. Rinse pouring edge with ether, adding rinsings to second separator. Ext soap soln with two 50 mL portions ether in same manner. Make total of 4 extns for marine oils or other oils of high unsaponifiable content.

Rotate combined ether exts gently with the 20 mL H<sub>2</sub>O (violent shaking at this stage may cause troublesome emulsions). Let layers sep. and drain aq. layer. Wash with two addnl 20 mL portions H<sub>2</sub>O, shaking vigorously. Then wash ether soln 3 times with alternate 20 mL portions ca 0.5*N* aq. KOH and H<sub>2</sub>O, shaking vigorously each time. If emulsion forms during washing, drain as much aq. layer as possible, leaving emulsion in separator with ether layer, and proceed with next washing. After third KOH treatment, wash ether soln successively with 20 mL portions H<sub>2</sub>O until washings are no longer alk. to phthln.

Transfer ether soln to 250 mL lipped, conical beaker, rinse separator and its pouring edge with ether, and add rinsings to main soln. Evap. to ca 5 mL and transfer quant., using several small portions ether, to 50 mL fat flask or erlenmeyer previously dried and weighed with similar flask as tare. Evap. ether. When nearly all ether has been removed, add 2–3 mL acetone, and while heating on steam or H<sub>2</sub>O bath, completely remove solv. in gentle air current. Dry at 100° for 30 min periods to const wt.

Dissolve contents of flask in 2 mL ether, add 10 mL neutzd (phthln) alcohol, and titr. with 0.1*N* alc. NaOH (or KOH). ( $\leq 0.10$  mL is usually required.) Correct wt residue for free fatty acid present (1 mL 0.1*N* alkali = 0.0282 g oleic acid).

Correct wt residue for reagent blank obtained by conducting detn similarly but omitting fat.

**Squalene (21)—Official Final Action****28.082****Reagents**

(a) *Concentrated potassium hydroxide soln*.—Dissolve 60 g KOH in 40 mL H<sub>2</sub>O.

(b) *Dilute potassium hydroxide soln*.—Dissolve 28 g KOH in H<sub>2</sub>O and dil. to 1 L.

(c) *Petroleum ether*.—Skellysolve B (bp 63–70°), or equiv.

(d) *Aluminum oxide adsorbent, 80–200 mesh*.—Adsorption alumina for chromatgc analysis, Fisher A-540, or equiv. Keep in tightly closed container, away from moisture.

(e) *Pyridine sulfate bromide soln.*—0.1*N*. (Caution: See 51.047, 51.072, and 51.081.) Dissolve 8 g Br in 20 mL HOAc. Prep. another soln by gradually adding, with cooling, 5.45 mL H<sub>2</sub>SO<sub>4</sub> to mixt. of 20 mL HOAc and 8.15 mL pyridine. Mix 2 solns, cool, and dil. to 1 L with HOAc.

(f) *Sodium thiosulfate std soln.*—0.05*N*. Prep. daily by dilg 0.1*N* soln, 50.037–50.038.

## 28.083

**Apparatus**

*Adsorption column.*—Prep. fresh column for each detn immediately before use. Place small wad of cotton in constricted end of glass tube, 8 mm id and 30 cm long. (For convenience, column may have Teflon stopcock in stem and top reservoir of  $\geq 40$  mL capacity.) Add alumina adsorbent in ca 10 small portions until column is ca 10 cm high. Apply gentle suction and tamp each portion alumina lightly with flattened end of heavy glass rod. Place small wad of cotton on top of column and tamp lightly. Wash column with ca 15 mL pet ether, remove suction, and keep top of column covered with shallow layer of pet ether until ready for use.

## 28.084

**Determination**

(Caution: See 51.011, 51.039, and 51.073.)

Accurately weigh ( $\pm 20$  mg) ca 5 g sample into 125 mL erlenmeyer with  $\frac{3}{4}$  joint, add 3 mL concd KOH soln and 20 mL alcohol, and boil under air condenser 30 min, shaking occasionally. Cool somewhat, and while still warm, add 50 mL pet ether; mix, and transfer to separator. Rinse flask with 20 mL alcohol and then with 40 mL H<sub>2</sub>O, adding rinsings to soln in separator. Shake vigorously, let sep. completely, and slowly drain soap soln. Pour pet ether ext from top of separator into another separator contg 20 mL H<sub>2</sub>O. Repeat extn of soap soln with 50 mL pet ether. Rotate combined exts gently with the 20 mL H<sub>2</sub>O and, after letting layers sep., discard wash H<sub>2</sub>O. Repeat washing by shaking vigorously with 20 mL H<sub>2</sub>O and again discard lower layer after sepn. Wash pet ether soln with 20 mL dil. KOH soln and then with 20 mL portions H<sub>2</sub>O until wash liq. is alkali-free, shaking vigorously each time. After final washing, drain last drops of H<sub>2</sub>O brought down by swirling separator. Pour pet ether soln from top of separator into lipped conical beaker. Rinse separator with pet ether and add rinsings to beaker. Add few pieces of broken porcelain or SiC and evap. almost all of solv. on steam bath. Remove last traces of solv. in current of CO<sub>2</sub> or other inert gas while warming beaker. To avoid oxidn of residue, do not expose to air while still warm.

Dissolve unsaponifiable matter in 5 mL pet ether and transfer to adsorption column. (Eluate, which is caught in 250 mL g-s l flask, should emerge dropwise, ca 1 mL/min but no faster, gentle pressure being used if necessary.) When soln has been nearly drawn into column, add ca 5 mL pet ether previously used to rinse beaker. Continue adding solv., previously used to rinse beaker, in 5–10 mL portions, always keeping surface of column covered with liq., until total of 50 mL has eluted. (If column with Teflon stopcock and top reservoir is used, proceed as above thru addn of 5 mL rinse; then rinse beaker with remaining 40 mL pet ether, add to reservoir, and let pass thru column.)

Add few pieces of broken porcelain or SiC and remove most of solv. on steam bath. Finally pass current of CO<sub>2</sub> or other inert gas thru heated flask until last traces of solv. are expelled. Cool residue to room temp. under inert atm. (All traces of solv. must be removed before detn is continued.)

Dissolve unadsorbed residue in 5 mL CHCl<sub>3</sub> and add enough pyridine sulfate bromide soln to provide  $\geq 50\%$  excess (10 mL is usually adequate). Let mixt. remain in dark 5 min and then

add 5 mL 10% KI soln, together with 40 mL H<sub>2</sub>O. Mix thoroly, wash down any free I on stopper, and titr. with 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Toward end of titrn add starch indicator, 2.144(b), shake vigorously, and continue titrn to disappearance of blue. Conduct blank detn on pyridine sulfate bromide soln similarly and calc. mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> equiv. to absorbed halogen. Blank detn on all reagents used should show practically no halogen consumption. 1 mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 1.71 mg squalene. Report results as mg squalene/100 g sample.

**Vegetable Fats in Butterfat****Sterol Acetate Melting Point Method (22)****Official Final Action**

## 28.085

**Apparatus**

(a) *Special micro filter.*—See Fig. 28.06.

(b) *Platinum spatula.*—Heavy Pt wire, hammered flat, to ca 3 mm wide  $\times$  15 mm long, on one end. Mount in dissecting needle holder.

## 28.086

**Determination**

To 15 g filtered fat in 150 mL beaker add 4 g KOH dissolved in 4 mL H<sub>2</sub>O. Add 20 mL 95% alcohol, cover with watch glass, and heat 0.5 hr on steam bath, stirring occasionally.

Add 60 mL H<sub>2</sub>O, mix, and pour into 400 mL beaker contg 180 mL 95% alcohol. Warm to ca 40° and add 40 mL 1% *digitonin in alcohol*. (Heat may be necessary to dissolve digitonin.) Stir and let stand overnight in refrigerator.

Filter cold mixt. with strong suction on rapid qual. 11 cm paper in buchner. When liq. has passed thru, pour 50 mL H<sub>2</sub>O over paper without stopping suction. Swirl occasionally. Continue to apply strong suction (H<sub>2</sub>O filters rather slowly) until all H<sub>2</sub>O has passed thru paper to wash out most of soaps. Pour 50 mL alcohol over paper and continue suction until all liq. has passed thru. Finally wash paper with four 50 mL portions ether, letting each portion pass thru completely before adding next.

Dry paper and ppt 15 min at 100°. Sep. ppt from paper. Crush or crumble ppt, and place it in 18  $\times$  150 mm test tube. Add 2 mL Ac<sub>2</sub>O and heat in 130° glycerol bath 15 min. (Ppt should dissolve

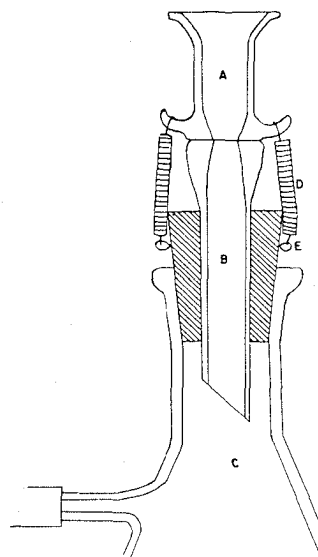

FIG. 28.06—Glass micro filter for sterol acetate precipitates. A: Top portion of filter, capacity 1 mL. B: Lower portion of filter. Ground surfaces between A and B hold filter pad. A and B are held together by springs. D, C, filter flask. E, wire twisted around stopper to hold lower end of springs.

in ca 5 min; do not use direct heat, since spattering may occur and material may be lost.) Cool to ca 70°.

Carefully add 4 mL alcohol and mix. Filter hot soln by gravity thru pledget of cotton in micro filtering tube (Pregl type), receiving filtrate in 20 mL beaker. Place beaker on small hot plate and carefully bring liq. to gentle boil. Add H<sub>2</sub>O drop by drop until sterol acetate is just about to ppt but still remains in soln at bp.

Let cool, stirring occasionally with Pt spatula, for 15–20 min or longer. Filter on small disk of paper in micro buchner (ca 15 mm diam.). Suck dry and sep. ppt from paper. Place ppt in 5 mL beaker and heat with 1 mL 95% alcohol to dissolve completely. Cool beaker by setting in petri dish of ice-H<sub>2</sub>O. When thoroly chilled, material usually sets to semisolid cryst. slurry.

Transfer slurry to special microfilter, using Pt spatula, and apply suction. As liq. is drawn thru filter, compact ppt by tamping with flat end of glass rod of suitable size. (Ppt can then be cleanly and completely removed from paper in form of small button or tablet.) Redissolve ppt in same 5 mL beaker with addnl 1 mL hot alcohol (or 0.5 mL if ppt is very small), and after chilling to recrystallize, filter second time on microfilter. Repeat recrystn and filtration third and fourth time; then dry ppt 1 hr at 100°.

Det. mp of recrystd, dried sterol acetates (temp. at which liq. first starts to run, detd when heated at rate of 0.5–1.0°/min). If mp is  $\geq 2^\circ$  higher than that of pure butter similarly treated, vegetable fat is indicated.

#### 28.087

#### Microcrystal Test

Dissolve sterol acetate remaining from mp detn in 2 mL alcohol in 20 mL beaker and add 3 drops 40% aq. KOH. Heat on steam bath 5 min. Add 10 mL H<sub>2</sub>O and transfer liq. to 125 mL separator. Add 25 mL ether and shake. Let layers sep.; then drain and discard aq. layer. Wash ether with three 5 mL portions H<sub>2</sub>O and evap. ether to dryness in 50 mL beaker.

Add 10 mL 70% alcohol to residue and heat to dissolve. Cool, place drop of clear soln on slide, and examine drop microscopically at 100–200 $\times$  for typical crystals of phytosterol or phytosterol-cholesterol mixt. (see Fig. 28:07).

#### 28.088 Digitonin Recovery—Procedure

Combine filtrates from digitonide pptns and add enough cholesterol dissolved in alcohol to combine with all digitonin present. Let mixt. stand 3 hr or overnight. Filter off ppt and wash with H<sub>2</sub>O, alcohol, and ether; then suck dry. Crush ppt and tamp it lightly into paper extn thimble. Suspend thimble in 3 erlenmeyer closed by reflux condenser and contg small amt of xylene. Heat xylene to bp and let thimble and contents hang in hot vapors of boiling xylene 16 hr.

Remove thimble and dry at 100° until xylene has evapd. Remove digitonin residue, weigh, and transfer to beaker. Dissolve residue in enough H<sub>2</sub>O to make ca 2% digitonin soln. Add ca 1/2 vol. alcohol and heat on steam bath. Add 1 mL *n*-amyl alcohol (reagent grade), cool, and filter off digitonin compd on buchner of suitable size. Suck dry and transfer ppt to watch glass. Dry at 100° until all amyl alcohol is volatilized. Digitonin may then be pulverized and is ready for reuse.

#### Gas Chromatographic Method (Sterol Acetates) (23) Official Final Action

#### 28.089

#### Preparation of Sample

Obtain fat from butter by 16.210. Weigh 5–10 g filtered fat into 150 mL beaker and proceed as in 28.086, beginning "... add 4 g KOH ..." (Sterol acetate need not be recrystd unless mp is also desired.)

#### 28.090

#### Reagents

(a) *GLC column packing*.—(1) *Stationary phase*.—JXR, or OV-1, or OV-101 dimethylpolysiloxane, or OV-17, or OV-22 methylphenylpolysiloxane. (2) *Support*.—100–120 mesh Gas-Chrom Q. Com. prepd packing of 1 or 3% stationary phase available from Applied Science Laboratories, Inc., or Supelco, Inc.

(b) *Ethyl acetate*.—Distd in glass (Burdick and Jackson Laboratories, Inc., or equiv.).

(c) *Cholestane std soln*.—0.4  $\mu\text{g}/\mu\text{L}$ . Weigh 40.0 mg cholestane std (Applied Science Laboratories, Inc.) into 100 mL vol. flask and dil. to vol. with EtOAc.

(d) *Cholestane internal std soln*.—0.2  $\mu\text{g}/\mu\text{L}$ . Dil. 10.0 mL std soln, (c), to 20.0 mL with EtOAc.

(e)  *$\beta$ -Sitosterol acetate std soln*.—2.0  $\mu\text{g}/\mu\text{L}$ . Weigh 22.2 mg  $\beta$ -sitosterol acetate std (ICN Pharmaceuticals, Inc., Life Sciences Group, ca 90% pure) into 10 mL vol. flask and dil. to vol. with EtOAc. Com.  $\beta$ -sitosterol acetate is mixt. of campesterol acetate (earlier eluting minor component) and  $\beta$ -sitosterol acetate. Det. concn of  $\beta$ -sitosterol acetate in std by chromatographing 2–3  $\mu\text{L}$  std soln. Det. area of campesterol acetate and  $\beta$ -sitosterol acetate peaks by drawing lines tangent to sides of peak and intersecting baseline. Det. areas of resulting triangles by multiplying ht by 1/2 base.

$$\text{Concn } \beta\text{-sitosterol acetate} = (C_s \times P_s) / (P_s + P_c)$$

where  $C_s$  = mg sterol acetate std/mL,  $P_s$  = area  $\beta$ -sitosterol acetate peak, and  $P_c$  = area campesterol acetate peak.

(f) *Cholestane- $\beta$ -sitosterol acetate std mixture*.—0.2  $\mu\text{g}$  cholestane and 1.0  $\mu\text{g}$   $\beta$ -sitosterol acetate/ $\mu\text{L}$ . Mix equal vols (c) and (e).

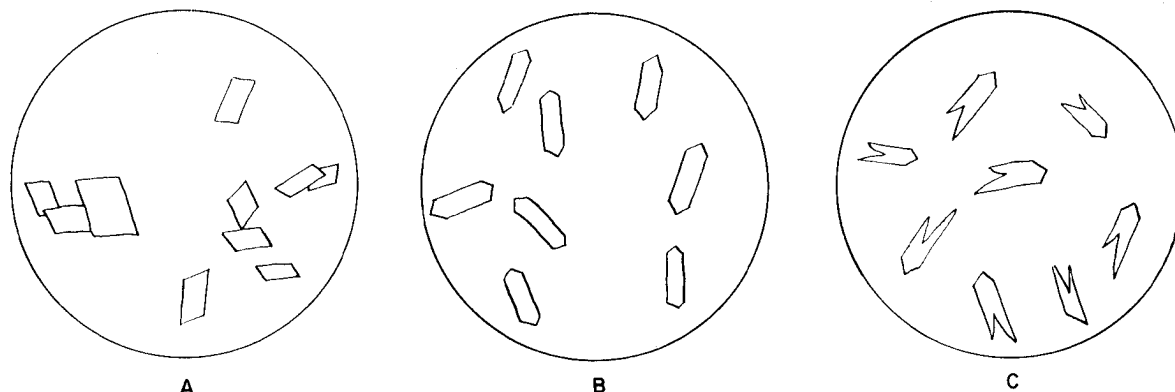

FIG. 28:07—Crystalline forms of free sterols. A: Cholesterol. B: Phytosterol. C: Mixed cholesterol-phytosterol

## 28.091

## Apparatus

(a) *Gas chromatograph*.—Barber-Colman Co. Model 5000 (replaced by Searle Analytic Series 4740), or equiv., with H flame ionization detector and 1 mv strip chart recorder. Temps (°): column, 220–260; flash heater and detector, 240–270; flow rates: N (ultra high purity grade), 20–25 psi (138–172 kPa) to elute  $\beta$ -sitosterol acetate in 16–20 min; H, ca 40–45 mL/min; air, 300–340 mL/min.

Adjust electrometer sensitivity so that 2.5  $\mu$ g  $\beta$ -sitosterol acetate gives ca 50% deflection ( $10^{-9}$ – $10^{-10}$  amp full scale deflection with 1 mv recorder). Repeat injections until const peak hts are obtained on successive injections of identical vols of std mixt.

(b) *Preparation of column*.—(Caution: See 51.039 and 51.040.) Pack glass column, 1.8 m (6')  $\times$  4 mm id, with com. 1–3% stationary phase on 100–120 mesh Gas-Chrom Q or dissolve 0.4–1.2 g polysiloxane in 200 mL toluene or  $\text{CH}_2\text{Cl}_2$ -toluene (1+1). Heat to dissolve (polysiloxane dissolves slowly in solv. mixt.). (Caution: Siloxanes are toxic. Wear disposable gloves and use effective fume removal device when handling.) Add soln to 40 g Gas-Chrom Q and let stand 10 min with occasional gentle stirring. Dry in rotary evaporator held in 50° bath or heat on steam bath with occasional gentle stirring and remove residual solv. in vac. oven at 50°.

Carefully wash inside of column and small amt glass wool with 5% soln *dichlorodimethylsilane* in toluene, rinse with MeOH until rinsings are neut. to indicator paper, and air dry. Plug column exit with small plug of silanized glass wool and thru-hole septum, and plug injection side arm with  $\frac{1}{2}$  hole septum. Add coated packing material thru injection port, using funnel and plastic tubing and tapping column very gently during addn. Add  $\frac{1}{4}$  packing material at time, remove funnel, and apply ca 5–10 psi (34.5–69 kPa) N to injection port while tapping gently to settle packing. Pack to 2.5 cm below injection side arm and plug with silanized glass wool.

(c) *Conditioning of column*.—Heat  $\geq 8$  hr at 260° with ca 5–10 psi (34.5–69 kPa) N flowing thru column. Shut off pressure, raise temp. to 290°, and continue heating  $\geq 8$  hr. Reduce temp. to 260°, adjust N to 5–10 psi, and heat addnl 8–12 hr.

(d) *Performance*.—Chromatograph ca 2  $\mu$ L  $\beta$ -sitosterol acetate std soln to det. retention times and resolution of column. Min. of 1600 theoretical plates is required for  $\beta$ -sitosterol acetate peak.

$$\text{Theoretical plates} = (L/B)^2 \times 16,$$

where  $L$  = mm  $\beta$ -sitosterol acetate peak from injection point and  $B$  = mm triangulated base width of  $\beta$ -sitosterol acetate peak.

## 28.092

## Determination

Pipet 1.0 mL cholestane internal std soln into 3 dram vial contg sterol acetates, rotate vial to wash down sides, and swirl to dissolve. Inject 2–3  $\mu$ L sample soln and 2–3  $\mu$ L std mixt., (f), at least in duplicate. Identify  $\beta$ -sitosterol acetate peak in sample from retention time in std mixt. If ht of sample peak is  $>60\%$  full scale, add addnl 1.0 mL internal std soln to sample soln, and rechromatograph sample and std mixt. solns. Measure peak hts of cholestane and  $\beta$ -sitosterol acetate peaks in mm.

$$\text{mg } \beta\text{-Sitosterol acetate/100 g sample} = (H_i/H_s) \times (C_s/C_i) \times (S_x/S_i) \times (Q_i/Q) \times 100,$$

where  $H_i$  and  $H_s$  = ht (mm) cholestane and  $\beta$ -sitosterol acetate peaks, resp., in std mixt.;  $S_x$  and  $S_i$  = ht (mm)  $\beta$ -sitosterol acetate and cholestane peaks, resp., in sample;  $C_x$  and  $C_i$  =  $\mu$ g  $\beta$ -sitosterol acetate and cholestane/ $\mu$ L, resp., in std mixt.;  $Q_i$  =  $\mu$ g cholestane/ $\mu$ L in sample; and  $Q$  = mg sample/ $\mu$ L.

## Beta-Sitosterol in Butter Oil (24)—Official First Action

(Applicable to samples contg  $\geq 4$  mg free  $\beta$ -sitosterol/100 mg butter oil)

## 28.093

## Principle

Free 3- $\beta$ -OH sterols are removed from butter oil by complexing with digitonin, and sterols are then removed from digitonide-Celite column by elution with dimethyl sulfoxide (DMSO). (Caution: DMSO can be harmful. Avoid skin contact by wearing heavy rubber gloves. Use effective fume removal device.) Butter oil has apparent range of 0–1 mg  $\beta$ -sitosterol/100 g and ice cream has apparent value of ca 4 mg/100 g fat from emulsifiers.

## 28.094

## Reagents

(a) *Diatomaceous earth*.—Celite 545, or equiv.

(b)  *$\beta$ -Sitosterol std soln*.—2  $\mu$ g  $\beta$ -sitosterol/ $\mu$ L  $\text{CHCl}_3$ . Prep. from Applied Science Laboratories, Inc., std (95%  $\beta$ -sitosterol, 5% campesterol).

(c) *n-Hexane*.—Distil pure grade over KOH. (Caution: See 51.011, 51.037, 51.039, and 51.061.)

## 28.095

## Apparatus

(a) *Gas chromatograph*.—Operating conditions: temps (°): column 225–245 and injection port and flame ionization detector 265–285. Adjust N carrier gas flow (ca 50–60 mL/min) to obtain following retention times (min): cholesterol 16–18, campesterol 22–24, and  $\beta$ -sitosterol 28–30. Use 1.8 m (6')  $\times$  4 mm id column contg 3% JXR silicone on 100–120 mesh Gas-Chrom Q and condition column 24 hr at 250° with 15–20 psi (103.4–138 kPa) N.

(b) *Performance*.—Monitor performance of gas chromatograph by noting sepn of campesterol and sitosterol expressed as peak resolution =  $2D/(C+B)$ , where  $D$  = distance between the 2 peak maxima,  $C$  = campesterol peak base width, and  $B$  =  $\beta$ -sitosterol peak base width. Peak resolution should be  $\geq 1.6$ .

(c) *Injection technic*.—With 10  $\mu$ L Hamilton microsyringe, draw 1  $\mu$ L air into barrel, insert needle into soln, and draw desired amt into barrel. Remove needle from soln and draw 1  $\mu$ L air into barrel. Note vol. on scale and adjust to desired vol., if necessary.

(d) *Preparation of std curve*.—Prep. std soln of 2  $\mu$ g  $\beta$ -sitosterol/ $\mu$ L  $\text{CHCl}_3$ . (Det. composition of std as in 28.090(e).) Obtain std curves daily covering range 1–10  $\mu$ g  $\beta$ -sitosterol, using  $\geq 3$  points. Plot area of  $\beta$ -sitosterol peak against  $\mu$ g  $\beta$ -sitosterol.

## 28.096

## Preparation of Column

Dissolve, with heating, 300 mg *digitonin* in 5 mL  $\text{H}_2\text{O}$ , add to mortar and pestle contg 10 g Celite, and mix thoroly. (Packing material can be kept several months if stored at 5° in tightly closed container.) Transfer 3 g Celite-digitonin mixt. to 2  $\times$  12 cm tube with ca 5 mm id outflow tube and small glass wool pad at bottom, and closed with short length of gum rubber tubing and pinchcock. Pack firmly, using tamping rod. (Flow rate of tightly packed column is 0.5–0.75 mL/min.) Sat. column with 5 mL *n*-hexane and let flow thru packing until *n*-hexane reaches top of packing material. Use column immediately. Do not let dry.

## 28.097

## Preparation of Sample

Dissolve 900 mg butter oil in 3 mL *n*-hexane. Quant. transfer soln, using disposable pipet, to digitonin-Celite column and let pass thru column until soln has entered packing material. Wash sample beaker twice with 2 mL *n*-hexane and add each wash to

column, rinsing sides of tube. Wash column with five 2 mL portions *n*-hexane. After all hexane has entered column, wash with five 2 mL portions benzene. When last portion benzene reaches ca 1 cm above top of packing material, remove rubber tubing and wash inner and outer surface of column tip thoroly with benzene to remove traces of fat. (Failure to wash column sides and column tip with solv. will result in poor chromatograms due to interference from triglycerides.) Discard hexane and benzene. Begin elution with 10 mL DMSO before benzene falls below top of packing material. Collect DMSO eluate in 15 mL screw-cap centr. tube.

Add 3 mL *n*-hexane to eluate, shake, and centr. Transfer upper layer contg sterols to second screw-cap centr. tube. Repeat extn of DMSO layer in first tube with two 4 mL portions *n*-hexane-benzene (1+1), carefully transferring upper layer to second tube each time. Vigorously shake pooled upper layers with 3 mL H<sub>2</sub>O and centr. until clear. Remove upper layer and evap. under N or filtered air in 30 mL beaker on steam bath. Transfer residue to 0.5 dram screw-cap vial with two 0.8 mL portions CHCl<sub>3</sub>. After evapg solv. with N or filtered air over steam bath, redissolve sterols in 0.1 mL CHCl<sub>3</sub> for GLC analysis.

**28.098****Determination**

Inject 2–8  $\mu$ L extd sample and calc.  $\beta$ -sitosterol by converting peak area to wt, using daily std curve.

$$\text{mg } \beta\text{-Sitosterol/100 g butter oil} = (\mu\text{g from curve}/1000) \times (100/\mu\text{L injected}) \times (100/\text{g sample}).$$

Identify peaks from butter oil samples by comparing their retention times to retention times of known compds. Relative retention times are: cholesterol 1.0, campesterol 1.4,  $\beta$ -sitosterol 1.7.

**Animal Fats in Vegetable Fats and Oils****(Determination of Cholesterol) (25)****Official Final Action**

(Sterol fraction of some vegetable oils conts small amts of cholesterol. Sterol fraction of palm oil may contain considerable amt of cholesterol.)

**28.099****Preparation of Sample**

Saponify and ext unsaponifiable matter from  $2.5 \pm 0.01$  g fat as in par. 1 and 2, **28.081**. Discard aq. solns. Transfer ether ext to 250 mL beaker and evap. to dryness on steam bath under N. Dissolve unsaponifiable matter in 4–5 mL CHCl<sub>3</sub>, transfer to 4 dram vial, and evap. to dryness. Rinse beaker with three 3 mL portions CHCl<sub>3</sub>, taking special care to dissolve any material on sides of beaker. Transfer rinsings to vial and evap. to dryness under N. Store samples in freezer.

**Isolation of Sterols by Thin Layer Chromatography****28.100****Reagents and Apparatus**

(a) *TLC plates*.—Prep. from silica gel PF 254 + 366 or HF 254 + 366 (Brinkmann Instruments, Inc., or equiv.) as in **28.101**, or use precoated plates available as "Uniplat" (precoated with silica gel HF 254 + 366, 500  $\mu$ m thick; No. 2112) from Analtech, Inc., 75 Blue Hen Dr, Newark, DE 19711, or "Quanta Gram" (precoated with silica gel PQ1F with fluorescent indicator, 500  $\mu$ m thick; No. 4811-830) from Whatman, Inc., 9 Bridewell Place, Clifton, NJ 07014.

(b) *Chloroform*.—Distd in glass (Burdick and Jackson Laboratories, Inc., or equiv.)

(c) *Ethyl ether*.—Anhyd.,  $\leq 0.01\%$  alcohol (Fisher Scientific Co. E-138, or equiv.)

(d) *Petroleum ether*.—Distd in glass, bp 30–60° (Burdick and Jackson Laboratories, Inc., or equiv.)

(e)  *$\beta$ -Sitosterol std soln.*—3  $\mu$ g/ $\mu$ L. Weigh 30.0 mg  $\beta$ -sitosterol std (Aldrich Chemical Co., Inc.) into 10 mL vol. flask and dil. to vol. with EtOAc. Com. material is mixt. of campesterol (earlier eluting component) and  $\beta$ -sitosterol.

(f) *Thin layer chromatographic apparatus*.—See **26.001(k)**.

(g) *Thin layer plate scraper*.—Optional; adapt from sealing tube with fritted disk (Corning Glassworks 39580, 30M). See Fig. **26.02**.

**28.101****Preparation of Plates**

Align 5 matching 20  $\times$  20 cm glass plates on mounting board, and just before coating, wipe plates with tissue dampened with alcohol to remove any dust or fingerprints. Adjust applicator to deliver 0.5 mm thick layer. Weigh 45 g silica gel into 500 mL erlenmeyer, add 130 mL H<sub>2</sub>O, shake vigorously 25–30 sec, and pour into applicator. Immediately coat plates with silica gel suspension and let plates rest undisturbed until gelled (0.5–1 hr). Dry coated plates  $\geq 2$  hr at 110° and store in desiccating cabinet until just before use.

**28.102****Thin Layer Chromatography**

(Caution: See **51.016**, **51.040**, and **51.056**.)

Line developing chamber with blotting paper and add 100 mL ether-pet ether (1+1) to chamber. Cover chamber and equilibrate 2 hr.

Draw line across plate 17 cm from bottom and ca 1 cm from each side. Spot 10  $\mu$ L  $\beta$ -sitosterol std soln, (e), at point 2 cm from bottom edge and 3 cm from 1 side of plate. Dissolve unsaponifiable matter, **28.099**, in 200  $\mu$ L CHCl<sub>3</sub> and spot entire sample in 10  $\mu$ L portions on imaginary line 2 cm from bottom edge of plate so that spot centers are 0.75 cm apart. Rinse vial with ca 100  $\mu$ L CHCl<sub>3</sub> and spot rinse soln in equal portions on top of sample spots.

Immediately insert plate into equilibrated chamber (position plate to expose coated surface to max. chamber vol.); cover chamber and seal with tape. Withdraw plate from chamber when solv. front reaches 17 cm stop line. Evap. solv. and view plate under longwave UV light in darkened room. Mark off sterol band (same *R<sub>f</sub>*, 0.2–0.3, as  $\beta$ -sitosterol std) with needle, and remove sterol band as follows (do not remove  $\beta$ -sitosterol std): Scrape off sterol band with sq end of stainless steel spatula (Fisher No. 14-375-10, or equiv.) into 100 mL beaker and transfer with 20 mL CHCl<sub>3</sub> to 70 mm top diam. funnel contg folded 12.5 cm diam. filter paper (S&S 588, or equiv.). Ext sterols with five 10 mL portions CHCl<sub>3</sub> and evap. combined filtrate to near dryness on steam bath under N. Transfer residue to 3 dram vial (screw-cap with Al liner) with CHCl<sub>3</sub> and evap. to dryness under N. (Alternatively, remove sterol band with TLC plate scraper, elute sterols from silica gel with 70 mL CHCl<sub>3</sub> (fourteen 5 mL portions), and evap. solv. to near dryness on steam bath under N.)

**Gas Chromatography of Sterols****28.103****Reagents**

Use reagents **28.090(a)**, **(b)**, **(c)**, and **(d)** and following:

(a) *Cholesterol std soln.*—1.2  $\mu$ g/ $\mu$ L. Weigh 60.0 mg cholesterol std (Applied Science Laboratories, Inc.) into 50 mL vol. flask and dil. to vol. with EtOAc.

(b) *Cholestane-cholesterol std mixture*.—0.2  $\mu$ g cholestane and 0.6  $\mu$ g cholesterol/ $\mu$ L. Mix equal vols cholestane, **28.090(c)**, and cholesterol std solns.

(c) *Cholesterol- $\beta$ -sitosterol std mixture*.—0.6  $\mu$ g cholesterol and 1.5  $\mu$ g  $\beta$ -sitosterol/ $\mu$ L. Mix equal vols cholesterol and  $\beta$ -sitosterol, **28.100(e)**, std solns.

(d) *Cholesteryl acetate std soln.*—0.6  $\mu\text{g}/\mu\text{L}$ . Weigh 30.0 mg cholesteryl acetate std (ICN Pharmaceuticals, Inc., Life Sciences Group) into 50 mL vol. flask and dil. to vol. with EtOAc.

**28.104****Apparatus**

(a) *Gas chromatograph.*—Barber-Colman Co. Model 5000 (replaced by Searle Analytic Series 4740), or equiv., with H flame ionization detector and 1 mv strip chart recorder. Temps ( $^{\circ}$ ): column, 220–250; detector and flash heater, 240–270; flow rates: N (ultra high purity grade), 20–25 psi (138–172 kPa) to elute cholesterol in 8–12 min; H, ca 40–45 mL/min; air, 300–340 mL/min. Electrometer sensitivity  $1 \times 10^{-9}$  amp full scale deflection with 1 mv recorder.

Adjust electrometer sensitivity so that 1.5  $\mu\text{g}$  cholesterol gives ca 50% deflection. Repeat injections until const peak hts are obtained on successive injections of identical vols. of std mixt.

(b) *Preparation of column.*—See 28.091(b).

(c) *Conditioning of column.*—Heat 12–24 hr under conditions specified in 28.091(c).

(d) *Performance.*—Chromatograph ca 2  $\mu\text{L}$  cholesterol- $\beta$ -sitosterol std mixt. to det. retention times and resolution of column. Min. of 1600 theoretical plates is required for cholesterol peak; theoretical plates =  $(L/B)^2 \times 16$ , where  $L$  = cm cholesterol peak from injection point, and  $B$  = cm triangulated base width of cholesterol peak. In addn, sepn of cholesterol and campesterol peaks, expressed as peak resolution, should be  $\geq 2.2$ . Peak resolution =  $2D/(B + P)$ , where  $D$  = distance in cm between cholesterol and campesterol peak max.;  $B$  = triangulated base width of cholesterol peak; and  $P$  = triangulated base width of campesterol peak. Det. peak resolution on sample having ca equal amts cholesterol and campesterol (ca equal peak areas); sample injected should give peak hts 25–50% of chart width.

**28.105****Determination**

Pipet 1.0 mL cholestane internal std soln into 3 dram vial contg extd sterols, rotate vial to wash down sides with internal std soln, and swirl to dissolve sterols. Inject 2  $\mu\text{L}$  sample at least in duplicate. Repeat with 2  $\mu\text{L}$  cholestane-cholesterol std mixt. Identify cholesterol peak in sample from its retention time in std mixt. If cholesterol peak ht in sample is  $>60\%$  full scale deflection, add addnl 1.0 mL cholestane internal std soln to sample and chromatograph sample and std mixt. as above. Measure cholestane and cholesterol peak hts in mm.

Calc. mg cholesterol/100 g sample, correcting for internal std, as follows:

$$\text{mg Cholesterol/100 g} = (H_i/H_x) \times (C_x/C_i) \times (S_x/S_i) \times (Q_i/Q) \times 100,$$

where  $H_i$  and  $H_x$  = ht (mm) cholestane and cholesterol peaks, resp., in std mixt.;  $S_x$  and  $S_i$  = ht (mm) cholesterol and cholestane peaks, resp., in sample;  $C_x$  and  $C_i$  =  $\mu\text{g}$  cholesterol and cholestane/ $\mu\text{L}$ , resp., in std mixt.;  $Q_i$  =  $\mu\text{g}$  cholestane/ $\mu\text{L}$  in sample; and  $Q$  = mg sample/ $\mu\text{L}$ .

**28.106****Confirmatory Test**

Presence of cholesterol may be confirmed by GLC of sterol acetates. After detg cholesterol by GLC, evap. sample to dryness on steam bath under N. Cool and add 3 mL pyridine and 1 mL  $\text{Ac}_2\text{O}$ . Cap vial, swirl on steam bath until sterols dissolve, and continue heating on steam bath 1 hr. Evap., using N stream, until no odor of pyridine is detected. Chromatograph sterol acetates and cholesteryl acetate std solns and compare retention times of sample and cholesteryl acetate peaks.

**Rosin Oil****28.107 Qualitative Test—Procedure**

Polarize pure oil, or definite diln with pet ether, in 200 mm tube. Rosin oil has polarization in 200 mm tube of +30 to +40 $^{\circ}\text{S}$ , while most oils read between +1 $^{\circ}$  and -1 $^{\circ}$  (Lewkowitsch, "Chemical Technology and Analysis of Oils, Fats and Waxes," 6th Ed., 1, 350(1921)).

**Cottonseed Oil****28.108 Halphen Test (26)—Official Final Action**

(Caution: See 51.039, 51.040, and 51.048.)

Mix  $\text{CS}_2$  contg 1% S in soln with equal vol. amyl alcohol. Mix equal vols of this reagent and sample under examination, and heat in bath of boiling satd NaCl soln 1–2 hr. Presence of as little as 1% cottonseed oil produces pronounced characteristic red or orange-red soln. Depth of color is proportional, to certain extent, to amt of cottonseed oil present, and comparative tests with known mixts of cottonseed oil give approx. amt.

Different oils react with different intensities. Oils that have been heated to 200–210 $^{\circ}$  (Allen, "Commercial Organic Analysis," 5th Ed., 2, 177(1924)) and hydrogenated oils (Jamieson, "Vegetable Fats and Oils," 2nd Ed. (1943)) react with greatly diminished intensity. Heating 10 min at 250 $^{\circ}$  renders cottonseed oil incapable of giving reaction (Abs. J. Soc. Chem. Ind. 18, 711(1899)). Fat of animals fed on cottonseed meal or other cottonseed products may give pos. reaction by this test.

rv

**Cyclopropene Fatty Acids (27)—Official First Action****28.109****Principle**

Oil is dissolved in mixt. of BuOH and 1% S in  $\text{CS}_2$ , and heated in presence of light in closed tube. "Halphen" pigments which are formed are measured spectrophtrically.

**28.110****Apparatus**

(a) *Tubes.*—Culture tubes, 20  $\times$  150 mm with screw caps and Teflon liners, Pyrex No. 9825, or equiv., matched to within 0.01 A units when filled with  $\text{H}_2\text{O}$ .

(b) *Constant temperature oil bath.*—Maintained at 110 $^{\circ}$ .

(c) *Spectrophotometer.*—Covering range 340–600 nm, with voltage regulation system. Bausch and Lomb Spectronic 20 is satisfactory if 0.75" tube adapter is enlarged slightly with sandpaper wrapped around conical figure.

**28.111****Reagents**

(a) *n-Butanol.*—Redistil if color forms in solv. blank.

(b) *Dilute sulfur soln.*—1% pptd S in  $\text{CS}_2$ . Prep. daily.

(c) *Cyclopropene std.*—Cottonseed oil methyl esters contg known amt cyclopropene fatty acids (available from Supelco, Inc.).

**28.112****Determination**

Accurately weigh ca 200 mg oil sample into screw cap tube. Pipet 20 mL BuOH and 5 mL 1% S in  $\text{CS}_2$  into tube, cap tightly, and mix. Place in beaker contg propylene glycol maintained at 110 $^{\circ}$  in oil bath in hood. Keep hood light on. Hold propylene glycol level above top of tube contents. After 2.5 hr, cool tube to room temp. in beaker contg flowing tap  $\text{H}_2\text{O}$ . Wipe tube dry and clean with soft paper towel. Measure A within 4 hr at max. ca 547 nm against blank prepd with corn oil or other cyclopropene fatty acid-free oil. If sample A is  $<0.04$ , increase sample

size and oil blank up to 1 g and repeat detn. Det. amt of cyclopropene fatty acids from std curve prepd from cyclopropene std.

### Peanut Oil

#### 28.113 Modified Renard Test (28)—Official Final Action

(Caution: See 51.011, 51.039, and 51.054.)

Weigh 20 g oil into erlenmeyer. Saponify with alc. KOH soln, **28.025**; neutze exactly with HOAc (1+3), using phthln; and wash into 800–1000 mL flask contg boiling mixt. of 100 mL H<sub>2</sub>O and 120 mL 20% Pb(OAc)<sub>2</sub> soln. Boil 1 min and then cool pptd soap by immersing flask in H<sub>2</sub>O, swirling occasionally to cause soap to stick to sides. After cooling, decant H<sub>2</sub>O and excess Pb(OAc)<sub>2</sub> soln, and wash Pb soap with cold H<sub>2</sub>O and alcohol, 90% by vol. Add 200 mL ether, cork, and let stand until soap disintegrates; heat on H<sub>2</sub>O bath, using reflux condenser, and boil ca 5 min. With oils, most of soap will be dissolved; with lards, which contain much stearin, part of soap will be left undissolved. Cool ether soln of soap to 15–17° and let stand until all insol. soaps sep. (ca 12 hr).

Filter on buchner and thoroly wash insol. Pb soaps with ether. Wash ether-insol. Pb soaps into separator with jet of ether, alternating with HCl (1+3) at end of operation if little of soap sticks to paper. Add enough HCl (1+3) so that total vol. of acid is ca 200 mL and enough ether to make its total vol. 150–200 mL, and shake vigorously several min. Let layers sep., drain off acid layer, and wash ether once with 100 mL HCl (1+3) and then with several portions of H<sub>2</sub>O until H<sub>2</sub>O washings are no longer acid to Me orange. If few undecomposed lumps of Pb soap remain (indicated by solid particles remaining after third washing with H<sub>2</sub>O), break up by running off almost all H<sub>2</sub>O layer, adding little HCl, and shaking; then continue washing with H<sub>2</sub>O as before.

Distil ether from soln of insol. fatty acids and dry latter in flask by adding little absolute alcohol and evapg on steam bath. Dissolve dry fatty acids by warming with 100 mL 90% alcohol by vol. Cool slowly to 15°, shaking to aid crystn. Let stand 30 min at 15°.

In presence of peanut oil, crystals of arachidic acid sep. from soln. Filter, wash ppt twice with 10 mL alcohol, 90% by vol., and then with alcohol, 70% by vol., taking care to keep arachidic acid and wash solns at definite temp. in order to apply solubility corrections given below. Dissolve arachidic acid on filter with boiling absolute alcohol, evap. to dryness in weighed dish, dry, and weigh. To this wt add 0.0025 g/10 mL of 90% alcohol used in crystn and washing, if conducted at 15°; if conducted at 20°, add 0.0045 g/10 mL.

Mp of arachidic acid thus obtained is 71–72°. Wt arachidic acid × 20 = approx. wt peanut oil present. Arachidic acid has characteristic appearance and may be identified under microscope. As little as 5–10% peanut oil can be detected by this method.

#### Modified Bellier Test (29)—Official Final Action

(Applicable only in presence of olive, cottonseed, corn, and soybean oils)

#### 28.114

#### Reagents

(a) *Alcoholic potassium hydroxide soln.*—1.5*N*. Dissolve 10 g KOH in purified alcohol, **28.025**, and dil. to 100 mL with purified alcohol.

(b) *Hydrochloric acid.*—Sp gr 1.16. Dil. 83 mL concd acid (sp gr 1.19) to 100 mL with H<sub>2</sub>O. Check with sp gr spindle.

(c) *Alcohol.*—70%. Dil. 700 mL alcohol to 950 mL with H<sub>2</sub>O. Check by sp gr or refractive index and adjust if necessary.

#### 28.115

#### Test

Weigh 0.92 g or measure 1 mL sample into 125 mL erlenmeyer with  $\pi$  outer joint. If oil is measured, use short Mohr pipet with fairly large opening at tip, drain to lower mark, hold until meniscus stops rising in pipet, and drain to mark again. Add 5 mL alc. KOH soln, and heat 5 min on steam bath, using air condenser to avoid loss of alcohol. Swirl once or twice during saponification. Add 50 mL 70% alcohol and 0.8 mL of the HCl. Warm to dissolve any ppt that may form.

Insert thermometer and cool with continuous agitation so that temp. falls ca 1°/min. Observe turbidity temp. or clouding point, which is temp. at which definite ppt first appears. (If temp. of soln is above room temp., cooling may be accomplished in air or by occasionally immersing soln in H<sub>2</sub>O bath of temp. ≤5° below that of soln. Do not immerse flask below level of contents, and agitate continuously to prevent premature formation of turbidity by local cooling. Soln may be agitated by stirring with thermometer or by swirling flask. Observe turbidity temp. by looking thru soln toward good light, or toward dark background with good light coming from one side.)

If turbidity appears before temp. reaches 9° (olive oil) or 13° (cottonseed, corn, or soybean oils) presence of peanut oil is indicated. Confirm by **28.113**.

#### 28.116 Cold Test (30)—Procedure

(Applicable to refined winterized salad oils)

Fill 4 oz oil sample bottle with oil at 25°, cork tightly, and seal with paraffin. Completely submerge bottle in bucket contg finely cracked ice and add H<sub>2</sub>O until it rises to top of bottle. Keep bucket filled solidly with ice by removing any excess H<sub>2</sub>O and adding ice when necessary. After 5.5 hr remove bottle and examine oil. If it is properly wintered, sample will be brilliant, clear, and limpid.

#### 28.117 Tea Seed Oil in Olive Oil (31)—Official Final Action

For preliminary qual. test use following room temp. method: Measure exactly 0.8 mL Ac<sub>2</sub>O, 1.5 mL CHCl<sub>3</sub>, and 0.2 mL H<sub>2</sub>SO<sub>4</sub> into test tube (18 × 150 mm is convenient). Mix, and cool to room temp. Add 7 drops of oil to be tested directly to reagents, mix, and cool again. (To measure test oil, use glass tubing, 4 mm od, and ca 2 mm id; 7 drops should weigh ca 0.22 g.) If soln of oil in reagents is cloudy after mixing and cooling, add Ac<sub>2</sub>O dropwise, shaking after each addn until soln suddenly clears. Appreciable deviations from these amts, particularly in H<sub>2</sub>SO<sub>4</sub>, cause distinct variations in color intensities. Since mixed reagent deteriorates slowly, do not mix in advance of testing.

After 5 min, add 10 mL absolute ether from graduate and mix immediately by inverting once. Tea seed oil forms brown soln changing to intense red within min or so. This red reaches max. and then fades slowly within few min. Olive oil forms initial green soln on addn of ether. This color fades slowly to brown-gray, occasionally passing thru faint pink stage. Both olive oil and tea seed oil eventually fade to permanent light brown. Mixts of tea seed oil and olive oil show characteristic tea seed oil colors proportional in intensity to amt of tea seed oil present.

For approx. quant. estns, drop oil into reagents as described above and let remain at room temp. 5 min. In meantime, cool 10 mL portion absolute ether in ice-H<sub>2</sub>O. After 5 min, place test tube contg oil and reagents in ice-H<sub>2</sub>O 1 min, add cold ether (taking care that no H<sub>2</sub>O falls into test tube), and mix. Return tube to ice-H<sub>2</sub>O bath and let colors develop while it is immersed in ice-H<sub>2</sub>O. Colors develop slowly and reach max. within ca 5 min.

Use deepest red colors produced as basis for comparison, and because of short period of stable max. intensity do not test >3 oils at one time. Stds contg known amts of tea seed oil in olive oil that give little or no pink with this test should be run simultaneously with sample. Preliminary room temp. test gives indication of stds to be used in ice-H<sub>2</sub>O method.

#### Sesame Oil

##### 28.118 *Modified Villavecchia Test (32)—Official Final Action*

Add 2 mL furfural to 100 mL alcohol. Thoroughly mix 0.1 mL of this soln with 10 mL HCl and 10 mL sample by shaking in test tube 15 sec. Let mixt. stand 10 min, observe color, add 10 mL H<sub>2</sub>O, shake, and again observe color. If crimson color disappears, sesame oil is absent. (As furfural gives violet tint with HCl, it is necessary to use the very dil. soln specified.)

#### Foreign Fats Containing Tristearin in Lard (33) Official First Action

##### 28.119

##### *Principle*

Presence of beef fat, tallows, and similar fats, as well as hydrogenated and interesterified pork fat in pork fats and lard, is detected by detg difference between mp of crystd triglycerides and mp of fatty acids derived from these triglycerides. This value is large for pure pork fats and small for beef fats.

##### 28.120

##### *Determination*

Weigh 5 g melted and filtered lard into g-s graduate and add 20 mL warm acetone. Mix well, taking care that soln is clear and has temp. >30°. Let stand 16–18 hr at const temp. of 30°. Fine mass of crystals occupying ≤3 mL should then be found at bottom of graduate. Should vol. of crystals materially exceed 3 mL, take smaller amt of lard (3–4 g) for new test. If crystals obtained from 5 g lard are insufficient, increase wt lard and vol. acetone proportionately.

Decant supernate acetone soln from crystd glycerides. Add three 5 mL portions warm (30–35°) acetone from small wash bottle, taking care not to break up deposit in washing, and decant first 2 portions. Actively agitate third portion in graduate and by quick movement transfer crystals to small filter paper. Using wash bottle, wash crystals with 5 successive small portions of the warm acetone, and remove excess acetone by suction. Spread out paper and contents, breaking up any large lumps, and air dry at room temp.

Thoroughly comminute mass and det. mp of crystals in closed 1 mm tube, using app. similar to that of Fig. 28:08. Heat H<sub>2</sub>O in beaker rapidly to ca 55° and maintain this temp. until thermometer carrying mp tube registers 50°; then heat again and raise temp. of outer bath rather quickly to 67°. Remove burner. Mp is reached when fused substance becomes perfectly clear and transparent.

When mp of glycerides obtained by this method is <63.6°, presence of beef fat or other fat should be suspected, and mp of ≤63.2° is evidence that sample is not pure lard. Conduct detn with control sample of pure lard.

Confirm presence of foreign fat by taking mp of fatty acids prepd from glycerides. After detg mp, transfer crystd glycerides to 50 mL beaker, add 25 mL ca 0.5*N* alc. KOH, and heat on steam bath until saponification is complete. Pour soln into separator contg 200 mL H<sub>2</sub>O, acidify, add 75 mL ether, shake, and let stand. Drain aq. acid layer and wash ether soln ≥3 times with H<sub>2</sub>O. Transfer ether soln to clean, dry 50 mL beaker, evap. ether on steam bath, and finally dry acids at 100°. Let acids remain at room temp. ca 2 hr and det. mp. If mp of glycerides,

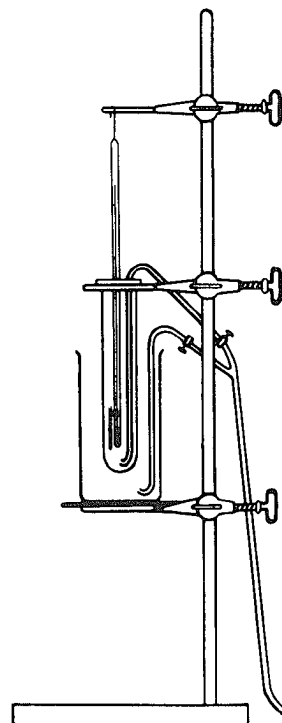

FIG. 28:08—Apparatus for determining melting point

plus twice difference between mp of glycerides and mp of fatty acids, is <73°, the lard is regarded as adulterated.

Conclusions may be confirmed further by precise detns of mean MW of sepd fatty acids. Dissolve acids in colorless, redistd alcohol, carefully neutzd immediately before use, and titr. with 0.5–0.2*N* KOH, using phthln. Mean MW = wt fatty acids × 1000/(mL × normality KOH used). If sample is pure lard, mean MW of fatty acids should correspond closely to that of fatty acids of  $\beta$ -palmitodistearin, 275.14. If sample is impure, mean MW should approach that of fatty acids from tristearin, 284.49.

##### 28.121 *Fish Oil and Marine Animal Oils in Presence of Vegetable Oils and in Absence of Metallic Salts (34)—Procedure*

(Caution: See 51.047.)

Dissolve 30 drops oil in 8 mL CHCl<sub>3</sub> in 50 mL beaker and add 10 mL Wijs soln, 28.020. Add from buret, with const stirring, Br-HOAc (1+3–4) to end point where soln appears to bleach out, and then add slight excess. Mix, immediately pour into flat-bottom test tube, and let stand 1–3 hr until clear supernate is obtained. Measure ht of ppt with mm rule and compare with stds prepd with known amts of fish oil, including 0. Amt of insol. bromides is proportional to amt of fish oil up to ca 15% and as little as 1% fish oil can be detected by slight ppt on standing overnight.

#### Mineral Oil in Fats (35)

##### 28.122 *Qualitative Test—Procedure*

Place 1 mL oil or melted fat in erlenmeyer; add 1 mL KOH soln (3+2) and 25 mL alcohol. Boil under reflux air condenser, shaking occasionally, until saponification is complete (ca 5 min). Add 25 mL H<sub>2</sub>O and mix. In presence of >0.5% mineral oil, distinct turbidity appears.

**28.123 Quantitative Method—Official Final Action**

(Caution: See 51.011, 51.039, and 51.073.)

Treat unsaponifiable residue, **28.081**, with  $\text{H}_2\text{SO}_4$  as below. When very small amts of mineral oil are present, enough unsaponifiable residue for test may be obtained as follows:

Saponify 100 g fat by refluxing under air condenser 2 hr with 55 mL KOH soln (3+2) and 240 mL alcohol, with occasional shaking. Cool, add 300 mL pet ether (bp 35–60°), and transfer to separator. Rinse flask with 240 mL alcohol and add rinsings to separator. Add 480 mL  $\text{H}_2\text{O}$  and shake vigorously. Let layers sep., drain lower layer, and transfer upper layer to another separator. Repeat extn of saponified fat with 300 mL pet ether, and combine exts. Wash ext twice with 60 mL portions  $\text{H}_2\text{O}$ , using gentle agitation. Repeat washing with 60 mL 0.5N KOH, followed by vigorous agitation with successive 60 mL portions  $\text{H}_2\text{O}$  until washings are alkali-free. Evap. ext to small vol. and dry with anhyd.  $\text{Na}_2\text{SO}_4$ .

Filter pet ether soln thru small cotton plug into Babcock milk-test bottle, **16.060(a)**, add few small pieces broken porcelain, and remove solv. by heating on steam bath while passing current of air thru bottle. Cool, add 5 mL  $\text{H}_2\text{SO}_4$ , mix, and keep bottle in boiling  $\text{H}_2\text{O}$  bath 30 min, shaking occasionally. Remove bottle from bath, cool, and fill with  $\text{H}_2\text{SO}_4$  until surface rises well into graduated neck. Centrf. 5 min at 1200 rpm and read vol. of unreacted residue. If enough mineral oil is available, obtain density as in **28.004**, using small Sprengel tube. Wt mineral oil can be closely approximated by multiplying vol. by 0.88. Refractive index of colorless residue should be <1.500 at 20°.

**Hydrocarbons (36)—Official Final Action****AOCS—AOAC Method**

(Applicable to satd hydrocarbons in glycerides)

**28.124****Apparatus and Reagents**

(a) *Chromatographic tube*.—With Teflon stopcock, 25–35 mm diam. and 400 mm long.

(b) *Aluminum oxide*.—Activated alumina, Alcoa, grade F-20, 80–200 mesh (Aluminum Co. of America, or equiv.). Dry alumina  $\geq 4$  hr at 200° before using. Store in sealed bottles in desiccator. Alumina must have moisture content of 0–3% to retain glycerides.

**28.125****Determination**

(Caution: See 51.011, 51.039, and 51.073.)

Weigh  $10 \pm 0.01$  g melted, well mixed sample into 125 mL erlenmeyer, and dissolve in 50–100 mL pet ether, warming gently, if necessary.

Prep. column by tamping plug of glass wool into bottom of tube so that some of glass wool is in constricted portion above stopcock. Fill tube ca  $\frac{2}{3}$  full with pet ether (Fisher Scientific Co. No. E-139, or equiv.) and add 200 g alumina thru powder funnel. Tap side of tube to aid in packing. Cover with ca 1 cm anhyd.  $\text{Na}_2\text{SO}_4$ . Elute at rate of 80–90 drops (3.0–3.5 mL)/min, using stopcock for control.

When solv. head drops to ca 1 cm, add sample soln. Let solv. layer drop to ca 1 cm above alumina, collecting eluate in 500 mL erlenmeyer. Rinse sample flask with 50 mL pet ether and add to column. Repeat 3 times, adding each rinse to column when solv. head drops to ca 1 cm, and wash down sides of column on transferring. Continue adding pet ether to column until total of 400 mL has passed thru. (Inverted vol. flask can serve as convenient reservoir for final addn of solv.)

Evap. eluate on steam bath to 50–75 mL. Stirring rod placed

in flask will help prevent superheating and consequent boiling over. Gentle air stream will aid solv. removal. Transfer to weighed 250 mL Soxhlet flask, rinsing with three 20 mL portions pet ether. Remove remaining solv. by evapn on warm surface with gentle air stream, keeping soln below bp. Cool to room temp. in desiccator and weigh.

Repeat with addnl heating periods of 20 min, cooling, and weighing until change in wt is <0.5 mg.

Conduct blank detn without sample.

$$\% \text{ Hydrocarbons} = (S - B) \times 100/C,$$

where  $S$  = g sample residue,  $B$  = g blank residue, and  $C$  = g sample.

**28.126****Precision**

Following 95% confidence limits may be expected:

	% Hydrocarbon Content at Level of			
	0.0	0.05	0.5	5.0
Two single detns in 1 laboratory should differ $\leq$	0.06	0.09	0.14	0.33
Single detns in different laboratories should differ $\leq$	0.06	0.10	0.14	0.40

Confirm presence of hydrocarbons or mineral oil by comparison of IR spectrum of residue with that of pure hydrocarbons or mineral oil, USP.

**Chick Edema Factor (Dioxins)****28.127 ★ Bioassay Method (37)—Official Final Action ★**

Chick feeding test. See 28.113–28.117, 12th ed.

**Gas Chromatographic Method (38)—Official First Action**

(Caution: See 51.011, 51.015, 51.030, 51.039, 51.040, and 51.073.)

**28.128****Principle**

Fat, oil, fatty acid, or lipid is treated with  $\text{H}_2\text{SO}_4$  and extd with pet ether. Ext is purified on  $\text{Al}_2\text{O}_3$  column, further treated with  $\text{H}_2\text{SO}_4$ , and examined by electron capture GLC. Peaks with retention times relative to aldrin ( $R_a$ ) between 8 and 45 indicate presence of chick edema factors (hexa-, hepta-, and octachlorodibenzo-*p*-dioxins).

**28.129****Reagents and Apparatus**

(Rinse all glassware with appropriate solvs before use. Do not store solvs in polyethylene containers. Solvs available from Burdick and Jackson Laboratories, or equiv.)

(a) *Petroleum ether*.—Distd in glass, bp 30–60°.

(b) *Ethyl ether for alumina chromatography*.—Ether ( $\leq 2\%$  alcohol) or absolute ether ( $\leq 0.01\%$  alcohol).

(c) Carbon tetrachloride.—Distd in glass.

(d) *Isooctane*.—Distd in glass.

(e) *Aldrin std soln*.—0.05  $\mu\text{g/mL}$  isooctane.

(f) *Chick edema factor low positive reference sample*.—1.5% Prep. from concd ref. toxic fat (available from Residue Analytical Chemistry Branch, Division of Chemistry and Physics, Bureau of Foods, Food and Drug Administration, Washington, DC 20204) in USP cottonseed or other vegetable oil. (Caution: Do not contact toxic fat.)

(g) *Activated alumina*.—Fisher Scientific Co. No. A-540; do not substitute. Activate 100 g portions by heating 4 hr at 260°. Transfer without cooling to dry container and close tightly. Check activity of  $\text{Al}_2\text{O}_3$  by analysis of low pos. ref. sample, (f).

★ Surplus method—see inside front cover.

examining  $\text{Al}_2\text{O}_3$  fractions 2 and 3. With sufficiently activated  $\text{Al}_2\text{O}_3$ , chick edema factor elutes predominantly or entirely in fraction 3 as indicated by gas chromatograms. (Chromatograms should show series of peaks with  $R_a$  between ca 8 and 45.)

(h) *Alumina chromatographic column*.—To dry tube, 17 (od)  $\times$  250 mm, fitted at bottom with coarse porosity fritted glass disk and Teflon stopcock (tube without disk but with glass wool plug at bottom may also be used), add redistd pet ether, dried before use with anhyd.  $\text{Na}_2\text{SO}_4$ , until tube is  $\frac{2}{3}$  full. Transfer 15 g  $\text{Al}_2\text{O}_3$  to tube in small portions, tapping to settle. After last portion has settled and air bubbles stop rising to surface of solv., add 5 g anhyd.  $\text{Na}_2\text{SO}_4$ . Drain excess pet ether until it is just above surface of  $\text{Na}_2\text{SO}_4$ .

(i) *Gas chromatographic column*.—Glass, 2.1–2.7 m (7–9')  $\times$   $\frac{1}{4}$ ", packed with 2.5% SE 52 silicone gum rubber on 60–80 mesh Gas-Chrom Q (Applied Science Laboratories, Inc.). Coat support with substrate as follows: Dissolve 2.5 g silicone gum rubber in 300 mL  $\text{CH}_2\text{Cl}_2$ -toluene (1+1) with heat. Add 97.5 g Gas-Chrom Q and let stand 10 min with occasional gentle stirring. Dry in rotary evaporator held in 50° bath. Apply vac. to chromatgc tube and add small amts of coated support while tapping tube at packing level after each addn. Fill to within 2.5 cm on exit side and 7.5 cm on entrance side and fill remaining space with silanized glass wool. Condition column at operating pressure 2–5 days at 250°.

(j) *Gas chromatograph*.—With tritium source concentric-type electron capture detector. Operate instrument in accordance with instructions of manufacturer. Obtain stable baseline before use. Choose operating voltage that will cause between 0.6 and full scale deflection for 0.1 ng aldrin (2  $\mu\text{L}$  std aldrin soln) at sensitivity setting of  $1 \times 10^{-9}$  amp full scale. Keep column temp. at  $200 \pm 1^\circ$  and adjust N flow so that aldrin elutes in 1–1.5 min (0.25–0.33" (6–8 mm)/min chart speed). Inject 2  $\mu\text{L}$  aldrin std soln before each ref. or test sample.

## 28.130

### Determination

(a) *Analysis of reference toxic fat*.—Dissolve 2.5 g ref. 1.5% toxic fat in 10 mL  $\text{CCl}_4$  in 500 mL g-s erlenmeyer and proceed as in (b), (c), and (d). Dissolve residue in 250  $\mu\text{L}$  iso-octane and inject 5  $\mu\text{L}$  (equiv. to 50 mg original sample) into gas chromatograph. Resulting chromatogram should exhibit series of peaks with  $R_a$  ca 8–45. Peaks at 8–13 are due to hexachlorodibenzo-*p*-dioxin isomers; 2 peaks at 17–22, to the 2 hepta-isomers; and peak at 35–45, to octa-isomer.

(b) *Preliminary sulfuric acid cleanup*.—Dissolve 2.5 g sample in 10 mL  $\text{CCl}_4$  in 500 mL g-s erlenmeyer. Add 10 mL  $\text{H}_2\text{SO}_4$ , stopper, and shake 30 sec. Add 125 mL pet ether, stopper, and shake vigorously ca 1 min. Let sep. and decant upper layer into 500 mL erlenmeyer, avoiding transfer of lower layer. Repeat extn with addnl 125 mL portion pet ether. Evap. combined pet ether exts to 5 mL.

(c) *Alumina chromatography*.—Before use, dry all solvs by shaking with anhyd.  $\text{Na}_2\text{SO}_4$ . Transfer evapd pet ether ext to alumina column, (h), using total of 10 mL pet ether. Let drain to just above level of  $\text{Na}_2\text{SO}_4$ . Keeping liq. level above  $\text{Na}_2\text{SO}_4$  at all times, elute with 100 mL pet ether (fraction 1), 50 mL 5% Et ether in pet ether (fraction 2), and 100 mL 25% Et ether in pet ether (fraction 3). (Flow rates of 8–9 mL/min are satisfactory.) Discard fractions 1 and 2 and collect fraction 3 in 125 mL erlenmeyer. Add several boiling chips and evap. to ca 2 mL on steam bath. Transfer residue with small portions pet ether to 10 mL g-s graduate and further evap. to 3 mL under N.

(d) *Additional sulfuric acid cleanup*.—Add 2 mL  $\text{H}_2\text{SO}_4$  to pet ether soln, stopper, and shake vigorously 30 sec. Let sep. and decant upper layer into 10 mL beaker, avoiding transfer of any

$\text{H}_2\text{SO}_4$ . Add 2 mL pet ether to graduate, swirl vigorously, let sep., and decant upper layer into beaker. Add 0.5 g solid  $\text{NaHCO}_3$  to beaker and stir ca 0.5 min. Let stand 5 min and decant pet ether layer into 2 or 4 dram vial. Wash  $\text{NaHCO}_3$  with 2 mL pet ether and decant washings into vial. Evap. solv. just to dryness at room temp. in vial under N.

(e) *Gas chromatography*.—Dissolve residue in 250  $\mu\text{L}$  iso-octane, stopper vial, and rotate to wet sides with solv. Inject 1  $\mu\text{L}$  soln (equiv. to 10 mg sample) into gas chromatograph, (j). Peaks with  $R_a$  of 8–45 indicate presence of chick edema factor. Compare  $R_a$  values with those from ref. toxic fat, (a). If peaks indicative of chick edema factor are not observed, inject 5  $\mu\text{L}$  soln (equiv. to 50 mg sample). (Types of samples found by experience to be free of components characteristic of toxic fats may be examined by initial injection of 5  $\mu\text{L}$ .)

Perform reagent blank detn with each set of samples. Smooth baseline should be obtained in region  $R_a$  8–45.

## Synthetic Colors (39)—Official Final Action

### 28.131

#### Reagents

(a) *Acid soln X*.—Mix 1 L HOAc with 200 mL HCl and 100 mL  $\text{H}_2\text{O}$ .

(b) *Acid soln Y*.—Cautiously add 400 mL  $\text{H}_2\text{SO}_4$  to 100 mL  $\text{H}_2\text{O}$ . When cool, add 900 mL HOAc and mix.

(c) *Sodium hydroxide soln*.—Approx. 25%. Dissolve 250 g NaOH in  $\text{H}_2\text{O}$  and dil. to 1 L.

### 28.132

#### Separation and Identification

(Caution: See 51.011, 51.039, and 51.073.)

Place 125 mL oil and 250 mL pet ether in each of 6 separators. Shake contents of first with 50 mL Soln X and, as soon as layers sep., transfer lower layer to flask contg 250 mL  $\text{H}_2\text{O}$ . Mix, and immediately ext this dild acid soln by passing successively thru two 500 mL separators, each contg 75 mL pet ether. Shake vigorously, let layers sep., and discard lower aq. layer. Repeat this procedure with each of other 5 separators, using same pet ether to re-ext colors from the dild acid solns. Combine the 2 pet ether exts, wash with three 25 mL portions  $\text{H}_2\text{O}$ , and filter.

Ext combined pet ether soln with two 25 mL portions Soln X. Treat each acid ext sep. by mixing with 150 mL  $\text{H}_2\text{O}$  and re-extg quickly by passing thru two 250 mL separators, each contg 50 mL pet ether. Combine these pet ether solns, wash acid-free with 15 mL portions  $\text{H}_2\text{O}$ , and evap. to dryness on steam bath. Do not heat dish after removal of solv. Residue may contain Ext. D&C Yellow No. 9 or No. 10 (formerly FD&C Yellow No. 3 or No. 4, resp.) and possibly trace of Ext. D&C Orange No. 4 (formerly FD&C Orange No. 2) if latter dye was originally present in large amts. Identify color spectrophtrically as in Chap. 34.

Shake first separator contg dild oil with 25 mL Soln Y, let sep. 20 min, and transfer lower layer to flask contg 200 mL 25% NaOH. Mix, and add 200 mL  $\text{H}_2\text{O}$ . Cool, and remove color from this alk. soln by passing successive 100 mL portions thru two 250 mL separators, each contg 75 mL pet ether. Discard extd alk. soln. Continue this Soln Y treatment of oil in other 5 separators, and finally combine the 2 pet ether exts. Wash with three 50 mL portions  $\text{H}_2\text{O}$  and ext with two 20 mL portions Soln Y, letting layers sep. 5 min. Drain lower layers into flask contg 300 mL 25% NaOH, mix, and add 300 mL  $\text{H}_2\text{O}$ . Cool, and remove color from this alk. soln by passing successive 100 mL portions thru 2 separators, each contg 75 mL pet ether. Combine pet ether solns, wash free from alkali with  $\text{H}_2\text{O}$ , transfer to evapd dish, and remove solv. on steam bath. Residue may contain Ext. D&C Orange No. 4 and D&C Green No. 6. Remove former by dissolving in 3–5 mL portions 60% alcohol and filtering each

portion thru small paper. Identify color spectrophtrically as in Chapter 34.

Dissolve residue on paper in 2–5 mL portions pet ether, collecting filtrate in original evapg dish. Remove solv. on steam bath. Blue residue indicates D&C Green No. 6. Dissolve residue in 15 mL alcohol and 10 mL H<sub>2</sub>O, and add 0.5 mL HOAc. Identify color spectrophtrically as in Chapter 34.

Pink color in the various acid exts usually indicates synthetic dye. However, corn oil sometimes produces faint pink color in these exts. This is readily differentiated from synthetic colors spectrophtrically. Chlorophyll may appear as green scum at interface in acid exts and as green residue on papers after filtration of pet ether solns.

## MONO- AND DIGLYCERIDES

### Glycerides in Monoglyceride Concentrates (40) Official Final Action

28.133

#### Apparatus

(a) *Chromatographic tube*.—Reservoir, 250 mL, with Teflon stopcock attached thru  $\frac{1}{8}$  19/22 drip tip inner joint to column, 19 (id)  $\times$  290 mm, with outer  $\frac{1}{8}$  19/22 joint at top and with coarse fritted glass disk and inner  $\frac{1}{8}$  19/22 joint at bottom. Bottom joint connects to adapter consisting of outer  $\frac{1}{8}$  19/22 joint connected to Teflon stopcock. (Available from SGA Scientific Inc., from Print No. 580241-12.)

(b) *Mixer*.—Patterson-Kelley Twin Shell Blender, or equiv., for mixing adsorbent. (Available from Patterson-Kelley Co., Inc., 100 Burson St, East Stroudsburg, PA 18301.)

28.134

#### Preparation of Silica Gel

Place ca 10 g silica gel (Fisher Scientific Co. No. S-679, grade 923, 100–200 mesh) in tared weighing bottle and cap immediately. Weigh to nearest mg and subtract tare wt. Remove cap and dry 2 hr at 200°. Remove from oven, cap immediately, and let cool 30 min at room temp. Raise cap momentarily to equalize internal pressure with atm. Weigh, reheat 5 min at 200°, cool, and reweigh. Repeat 5 min drying cycle until 2 consecutive wts agree within 10 mg. Calc. H<sub>2</sub>O content as follows:

% H<sub>2</sub>O in original silica gel =  $x = (\text{loss in wt}) \times 100 / \text{sample wt}$ . Adjust H<sub>2</sub>O content of original silica gel to 5% as follows:

H<sub>2</sub>O to be added =  $g \text{ original silica gel} \times (5 - x) / 95$ .

Weigh silica gel to be adjusted in blender and add calcd amt H<sub>2</sub>O to give final H<sub>2</sub>O content of  $5 \pm 0.1\%$ . Blend 1 hr to ensure complete H<sub>2</sub>O distribution and store in sealed container. Det. H<sub>2</sub>O content of adjusted silica gel as above, and readjust if necessary.

28.135

#### Preparation of Sample

(To avoid rearrangement of partial glycerides, use extreme caution in applying heat to samples. Do not heat  $> 50^\circ$ .)

(a) *Samples melting below 50°*.—Melt by warming at  $< 50^\circ$  for short periods (30 min max.).

(b) *Samples melting above 50°*.—Grind ca 10 g in mortar and pestle. If necessary, chill samples in solid CO<sub>2</sub>.

Weigh 0.9–1.1 g prepd sample to 1 mg in 100 mL beaker. Add 15 mL CHCl<sub>3</sub> and warm if necessary for complete soln. Use only min. heat and do not heat  $> 40^\circ$ .

28.136

#### Preparation of Column

Assemble chromatgc tube but without reservoir. Do not grease joints. Weigh 30 g prepd silica gel into 150 mL beaker and add 50–60 mL pet ether. Stir slowly with glass rod until all air

bubbles are expelled. Place powder funnel in tube and transfer slurry. Open stopcock and let liq. level drop to ca 2 cm above silica gel. To transfer any silica gel slurry remaining in beaker, invert beaker over powder funnel at  $45^\circ$  and wash into tube with wash bottle, using min. amt pet ether. Rinse funnel and sides of tube; when solv. level drops to 2 cm above silica gel, close bottom stopcock. Remove powder funnel and carefully add sample. Open stopcock and adjust flow to 2 mL/min. Rinse beaker with 5 mL CHCl<sub>3</sub> and add rinse to column when level drops to 2 cm above silica gel.

(Keep temp. of work area below bp of most volatile solv. used, Et ether (34.6°). Higher temp. will cause sepn of column packing and permit solv. to channel.)

Never let column become dry on top, and maintain 2 mL/min flow rate thruout elution. If necessary to interrupt elution, do so when very little glyceride is passing thru bottom stopcock. Avoid such interruptions, since solv. above bottom stopcock may cause pressure buildup and result in leakage thru stopcock or cracks in silica gel packing.)

28.137

#### Separation of Glycerides

(Caution: See 51.011, 51.039, 51.040, 51.045, and 51.054.)

Attach reservoir to column, add 200 mL benzene, and collect eluate in tared 250 mL flask (triglyceride fraction). When all benzene has been added from separator and level in column drops to 2 cm above silica gel, add 200 mL 10% (v/v) ether in benzene and collect eluate in second tared 250 mL flask (diglyceride + free fatty acid (FFA) fraction). When all benzene-ether solv. has been added from separator and level in column drops to 2 cm above silica gel, add 200 mL ether, change to third tared 250 mL flask, and collect monoglyceride fraction.

(Addn of Et ether to column often creates internal pressure, resulting in increased flow rate and cracks in silica gel packing before fraction is completely eluted. Avoid by slightly sepg reservoir from column for ca 30 sec and letting solv. flow into column at same rate as eluate is collected.)

To ensure quant. sepn of fractions, rinse tip of column into receiver with same solv. used in elution just before changing flasks for next eluate.

Evap. collected tri-, di- plus FFA, and monoglyceride fractions on steam bath under stream of N or dry air. Let flasks cool at room temp.  $\geq 15$  min and weigh. Reheat samples on steam bath 5 min under N or dry air, let cool 15 min, and reweigh. Repeat 5 min evapn, cooling, and reweighing until 2 consecutive wts agree within 2 mg.

Any free fatty acid present is eluted with diglyceride fraction. To det. free fatty acid content of weighed diglyceride, add 25 mL warm neut. alcohol and 1 drop phthln indicator, and titr. with 0.05N NaOH.

28.138

#### Calculations

% FFA (as oleic) =  $\text{mL NaOH} \times \text{Normality} \times 28.2 / \text{g sample}$

% Triglyceride =  $\text{g triglyceride} \times 100 / \text{g sample}$

% Diglyceride =  $(\text{g diglyceride} \times 100 / \text{g sample}) - \% \text{ FFA}$

% Monoglyceride =  $\text{g monoglyceride} \times 100 / \text{g sample}$ .

### 1-Monoglycerides (41)—Official First Action

#### American Oil Chemists' Society Method

28.139

#### Principle

1-Monoglycerides are detd from HIO<sub>4</sub> consumed in the oxidn of adjacent hydroxyl groups. 2-Monoglycerides are not oxidized by HIO<sub>4</sub>. Method is applicable to monoglyceride concs contg  $\geq 15\%$  1-monoglyceride; not applicable to samples contg CHCl<sub>3</sub>-sol. substances with  $\geq 2$  adjacent hydroxyl groups.

**28.140****Reagents**

(a) *Periodic acid soln.*—Reagent grade (available from G. Frederick Smith Chemical Co.). Test as follows: To 0.5–0.6 g glycerol in 50 mL H<sub>2</sub>O, add 50 mL HIO<sub>4</sub> soln from pipet. Prep. blank contg 50 mL H<sub>2</sub>O. Let stand 30 min and titr. as in **28.142**. Titer of soln contg glycerol/titer of blank = 0.75–0.76 if reagent is satisfactory.

Dissolve 5.4 g HIO<sub>4</sub> in 100 mL H<sub>2</sub>O, add 1900 mL HOAc, and mix thoroly. Store in g-s bottle in dark.

(b) *Starch indicator soln.*—Make homogeneous paste of 1.0 g sol. starch with H<sub>2</sub>O. Add to 100 mL boiling H<sub>2</sub>O, stir rapidly, and cool. Salicylic acid, 0.125 g/100 mL, may be added as preservative. Soln keeps longer if stored in refrigerator. Color of 2 mL starch soln dild with 100 mL H<sub>2</sub>O contg 0.05 mL 0.1*N* I must be discharged by 0.05 mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Discard if end point from blue to colorless is no longer sharp.

(c) *Chloroform.*—Reagent or USP. Blanks on HIO<sub>4</sub> soln with and without CHCl<sub>3</sub> must check within 0.5 mL.

**28.141****Preparation of Samples**

(Do not subject samples to excessive temps or monoglyceride content may be reduced.)

(a) *Solids in flake form.*—Mix without melting.

(b) *Solids not in flake form.*—Melt at ≤10° above mp, mix thoroly, and take sample. Do not test samples contg so much free glycerol that it seps on solidification.

(c) *Semisolids and liquids.*—Proceed as in (b).

**28.142****Determination**

Accurately weigh 0.3–2 g sample calcd from equation:  $g = 30/\%$  monoglyceride in sample, dissolve in CHCl<sub>3</sub>, and transfer to 100 mL g-s vol. flask. Dil. to vol. with CHCl<sub>3</sub> and mix. Transfer entire soln to 500 mL g-s erlenmeyer (do not rinse) and add 100 mL H<sub>2</sub>O. Stopper, and shake vigorously 1 min. Let stand until layers sep. and CHCl<sub>3</sub> layer is clear or only slightly cloudy (1–3 hr). If emulsions form, causing poor sepn, repeat detn, using 100 mL HOAc (5+95) instead of H<sub>2</sub>O.

Pipet 50 mL HIO<sub>4</sub> soln into series of 400 mL beakers. Add 50 mL CHCl<sub>3</sub> to 2 and 50 mL H<sub>2</sub>O to third as blanks (**28.140(c)**). Pipet 50 mL CHCl<sub>3</sub> sample soln into fourth, avoiding any aq. phase, and shake gently. (Solns must be cooled to <95°F (32°), if necessary.) Cover with watch glass and let stand 30 min.

Add 20 mL 15% KI soln, mix by gentle shaking, and let stand ≥1 min but ≤5 min, away from strong sunlight. Add 100 mL H<sub>2</sub>O, and titr. with stdzd 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, stirring continuously with mech. stirrer. After I color disappears from aq. layer, add 2 mL starch soln and continue titrn to disappearance of blue from aq. layer. Vigorous stirring is necessary to remove I from CHCl<sub>3</sub> layer.

If titer of sample is <0.8 titer of blanks, repeat detn, using smaller aliquot of CHCl<sub>3</sub> soln or smaller sample wt, to assure adequate excess of HIO<sub>4</sub>.

% Monoglyceride as monostearin =  $(B - S) \times N \times 17.927/W$ , where  $B$  = titer of CHCl<sub>3</sub> blank,  $S$  = titer of sample,  $N$  = normality of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>,  $W$  = g sample in CHCl<sub>3</sub> aliquot, and 17.927 = MW monostearin/20.

If content is to be calcd to monoglyceride other than monostearin, substitute for 17.927 MW of other monoglyceride/20. Alternatively, det. MW as follows: Sep. fatty acids as in first 2 par. of **28.014**. Accurately weigh ca 2 g fatty acids into 250 mL erlenmeyer and add 20–30 mL hot alcohol neutzd to faint pink of phthln. (SDA formula 30 or 3A is satisfactory.) Add 0.5 mL phthln and titr. immediately while shaking with 0.5*N* NaOH to pink that persists 30 sec. Calc. acid number (mg KOH required

to neutze fatty acids in 1 g sample) =  $\text{mL NaOH} \times \text{normality} \times 56.1/\text{g sample}$ . Av. MW of fatty acids =  $56104/\text{acid number} = M$ . MW monoglyceride =  $(M + 92.09) - 18.02$ .

Duplicate detns made on same day by 1 analyst should not differ (95% confidence limits) by more than ca 0.5, and 1.2% 1-monoglyceride at 40 and 90% levels; single detns and av. of duplicate detns made in 2 different laboratories should not differ by more than ca 1.2 and 3.2%, and 1.1 and 3.1%, resp., at same levels.

**Revised Miner Method (42)****28.143****Principle**

Periodic acid oxidizes vicinal hydroxyl groups. Compds with =O, —OH, —NHR, and —NH<sub>2</sub> attached to adjacent C atoms will be oxidized by H<sub>5</sub>IO<sub>6</sub>; phospholipids can interfere. Such substances are absent from usual fat samples.

Samples are dissolved in CHCl<sub>3</sub> contg 5% dimethylformamide (to assure soln of glycerol) and aliquots are oxidized with excess H<sub>5</sub>IO<sub>6</sub>. H<sub>5</sub>IO<sub>6</sub>-H<sub>2</sub>O soln exts and oxidizes free glycerol and H<sub>5</sub>IO<sub>6</sub>-MeOH soln oxidizes monoglyceride plus glycerol. Unused H<sub>5</sub>IO<sub>6</sub> is detd iodometrically by reacting with KI and titrg with 0.05*N* std arsenite soln.

Calcn of monoglyceride is based on amt of H<sub>5</sub>IO<sub>6</sub> consumed in oxidn of monoglyceride plus glycerol corrected for amt consumed in oxidn of free glycerol alone.

Method is applicable to fats, oils, shortenings, monoglycerides, and blends contg <15% 1-monoglycerides.

**28.144****Reagents and Apparatus**

(a) *Periodic acid stock soln.*—Dissolve 12.0 g H<sub>5</sub>IO<sub>6</sub> (G. Frederick Smith Chemical Co., reagent grade) in 100 mL H<sub>2</sub>O. Store at room temp. in brown g-s bottle.

(b) *Periodic acid in 95% methanol.*—Mix 25 mL stock soln with 475 mL MeOH. Store at room temp. in brown g-s bottle and prep. fresh every 3–5 days.

(c) *Periodic acid in water.*—Mix 50 mL stock soln, (a), with 950 mL H<sub>2</sub>O.

(d) *Potassium iodide soln.*—Dissolve 75 g KI and 50 g NaHCO<sub>3</sub> in H<sub>2</sub>O.

(e) *Sodium arsenite.*—0.05*N*. See **50.005–50.006**.

(f) *Starch indicator.*—Make homogeneous paste of 0.50 g potato starch with 5 mL H<sub>2</sub>O. Add to 200 mL boiling H<sub>2</sub>O and boil 15 min, stirring constantly. Cool and store in g-s bottle. Prep. fresh daily.

(g) *Chloroform.*—I absorption should be <0.1 mL 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>/30 mL solv.

(h) **N,N*-Dimethylformamide (DMF).*—25% soln in CHCl<sub>3</sub> (g). (Caution: This material is toxic. Avoid contact with skin or inhalation of vapors.)

(i) *Hot plate.*—Thermolyne, Model HP-A1915B, or equiv. (Thermolyne, 2555 Kerper Blvd, Dubuque, IA 52001).

**28.145****Preparation of Samples**

See **28.141**.

**28.146****Determination**

(Caution: See **51.018**, **51.040**, **51.053**, and **51.056**.)

Weigh sample into 100 mL beaker, calcg g required as:

$$S = K/(M' + 8G) = 50/(M' + 8G) = 4W_1 = 2W_2;$$

where  $M'$  = % monoglyceride expected;  $G$  = % free glycerol

expected;  $K$  = const which det<sup>s</sup> % excess reagent [ $100 T_1/(B_1 - T_1)$ ];  $W_1$  = aliquot wt for monoglyceride;  $W_2$  = aliquot wt for free glycerol;  $B_1$  = blank titrn for monoglyceride plus glycerol;  $B_2$  = blank titrn for free glycerol;  $T_1$  = sample titrn for monoglyceride plus glycerol; and  $T_2$  = sample titrn for free glycerol.

For 20% excess,  $K = 70$ ; 50% excess,  $K = 50$  (preferred); and 100% excess,  $K = 42$ . Max.  $S$  should be 40 g/100 mL or, if preferred, 10 g can be weighed directly into reaction vessel.

(a) *Monoglyceride plus glycerol*.—Dissolve weighed sample in 20 mL 25% DMF. Use  $\text{CHCl}_3$  to transfer quant. to 100 mL vol. flask and dil. to vol. Aliquots can be used for analysis of both monoglyceride plus glycerol and free glycerol.

Pipet 25 mL aliquot into 500 mL erlenmeyer and record sample wt in aliquot as  $W_1$ . Prep. 2 blanks in similar flasks by adding 5 mL 25% DMF and 20 mL  $\text{CHCl}_3$  to each.

Pipet exactly 25 mL  $\text{H}_5\text{IO}_6$ -MeOH into the 25 mL aliquot and into each blank. (For samples low in monoglyceride, such as triglyceride fat or oil, vol.  $\text{H}_5\text{IO}_6$ -MeOH may be reduced from 25 mL to 10, 5, or even 3 mL; use same amt of reagent for blanks.) Add 2–3 glass beads to each sample and heat just to bp on hot plate, swirling several times during heating. (Do not heat blanks.) Let stand 30 min to cool, protected from sunlight or other strong illumination. Add 200 mL  $\text{H}_2\text{O}$  to each blank and sample, and swirl several times. Let sample stand 5 min ( $\leq 45$  min is permissible). Blanks may be analyzed immediately. Add 40 mL KI soln from graduate and swirl to mix. Let stand 1 min; then titr. with Na arsenite. After I color fades to pale yellow, add 2–3 mL starch indicator and continue titrn until starch-I color disappears. Record av. titrn of 2 blanks as  $B_1$  and of sample as  $T_1$ . When  $>1$  sample is run on same day with same reagents, av. titrn of 2 blanks which check within 0.1 mL can be used in all calcs. If 2 blanks do not check within 0.1 mL, third blank must be run. Excess  $\text{H}_5\text{IO}_6$  must be 20–100%. If  $100 T_1/(B_1 - T_1)$  is  $<20\%$ , repeat with smaller sample; if excess is much  $>100\%$ , repeat with larger sample or use less  $\text{H}_5\text{IO}_6$ -MeOH. To complete  $\text{H}_5\text{IO}_6$  oxidn, min. of 20% excess is required. If excess  $\text{H}_5\text{IO}_6$ -MeOH is much  $>100\%$ , high apparent monoglyceride may result.

(b) *Free glycerol*.—Free glycerol must be extd completely from DMF layer into aq. layer. If glycerol is not in aq. layer when  $\text{H}_5\text{IO}_6$ - $\text{H}_2\text{O}$  is added, or during standing time, results may be low.

Pipet 50 mL aliquot of weighed sample from (a) into 500 mL erlenmeyer. Record sample wt in aliquot as  $W_2$ . Prep. 2 blanks in similar flasks by adding 10 mL 25% DMF and 40 mL  $\text{CHCl}_3$ .

Add ca 100 mL  $\text{H}_2\text{O}$  to sample and blanks. Swirl ca 1 min, reversing direction several times. Pipet exactly 25 mL  $\text{H}_5\text{IO}_6$ - $\text{H}_2\text{O}$  into each flask. Let stand at room temp. 30 min, swirling vigorously  $\geq 30$  sec at beginning and every 5 min during this period. Add 40 mL KI soln from graduate, swirl, and let stand 1 min. Titr. with 0.05N Na arsenite to starch-I end point as in (a), including blank titrns. Record sample titrn as  $T_2$  and av. of blank titrn as  $B_2$ . Any excess  $>20\%$  is permissible for  $\text{H}_5\text{IO}_6$ - $\text{H}_2\text{O}$ .

## 28.147

### Calculation

$$\% \text{ Monoglyceride} = \{[(B_1 - T_1) - (W_1/W_2)(B_2 - T_2)] \times N \times MW \times 100\} / (W_1 \times 2 \times 1000),$$

where  $N$  is normality of Na arsenite soln, and  $MW$  is molecular wt of monoglyceride.

Monoglyceride content can be calcd as monostearin. Using exactly 0.05N Na arsenite, 358 as MW of monostearin, and sample wt of free glycerol equal to twice amt used for monoglyceride plus glycerol, following formula can be applied:

$$\% \text{ Monoglyceride (as monostearin)} = \{[(B_1 - T_1) - 0.5(B_2 - T_2)] \times 0.895\} / W_1.$$

## Glycerides in Shortening (43)—Official Final Action

(Not generally applicable when emulsifiers other than mono- and diglycerides are present. *Caution:* See 51.011, 51.039, 51.040, 51.045, and 51.054.)

## 28.148

### Apparatus

See 28.133.

## 28.149

### Preparation of Silica Gel

See 28.134. Check each new lot of adsorbent for satisfactory sepn of glycerides. Collect last 15 mL of each eluate in weighed flask. If residue after evapn is  $>2$  mg, increase amt of eluate until last 15 mL collected contains  $<2$  mg. Once amts of eluates needed for complete sepn of glyceride fractions are established, only occasional checking of each lot of silica gel is required.

## 28.150

### Preparation of Sample

Melt entire sample in hot  $\text{H}_2\text{O}$  at  $50^\circ$  to avoid overheating, and mix well. Weigh 4.9–5.1 g prepd sample to 1 mg in 100 mL beaker. Add 10 mL benzene and warm if necessary for complete soln. Use only min. heat and do not heat  $>50^\circ$ .

## 28.151

### Preparation of Column

Prep. column as in 28.136 and adjust flow to 2 mL/min. Begin collecting eluate in weighed 400 mL beaker. Rinse beaker with 10 mL benzene and add to column when level drops to 2 cm above silica gel. Repeat rinsing with 10 mL portions benzene, using total of 40 mL.

Observe precautions of last 2 par. of 28.136.

## 28.152

### Separation of Glycerides

Attach reservoir separator to column, add 300 mL benzene, and collect eluate in weighed 400 mL beaker (triglyceride fraction). When all benzene has been added and level in column drops to 2 cm above silica gel, add 250 mL 10% (v/v) ether in benzene and collect eluate in second weighed 400 mL beaker (diglyceride fraction). When all benzene-ether solv. has been added and level in column drops to ca 2 cm above silica gel, add 200 mL ether and collect eluate in third weighed 400 mL beaker (monoglyceride fraction). Observe precaution of second par., 28.137.

To ensure quant. sepn of fractions, rinse tip of column into receiver before changing beakers for next eluate. (Weighed 300 mL Soxhlet flasks can be used for collecting fractions, but 2 will be required for triglyceride eluate.)

Evap. tri-, di-, and monoglyceride fractions on steam bath under stream of clean N or dry air. Let beakers cool at room temp.  $\geq 15$  min and weigh. Replace beakers on steam bath 5 min, remove, cool 15 min, and reweigh. Repeat 5 min evapn, cooling, and reweighing until 2 consecutive wts agree within 2 mg.

## 28.153

### Calculations

$$\begin{aligned} \% \text{ Triglyceride} &= \text{g triglyceride} \times 100/\text{g sample} \\ \% \text{ Diglyceride} &= \text{g diglyceride} \times 100/\text{g sample} \\ \% \text{ Monoglyceride} &= \text{g monoglyceride} \times 100/\text{g sample} \end{aligned}$$

High free fatty acid contents will give high results, since approx. 20% of free fatty acid is eluted with each of the tri- and monoglyceride fractions and 60% with diglyceride fraction. With most shortenings, effect is insignificant, since level of free fatty acids is  $<0.2\%$ .

Nonhydroxy-derived glycerides, which may be formed by thermal exposure, may interfere. This material is found primarily in diglyceride fraction. Significant amts are not present in fresh

shortenings. With used fats, diglyceride content of that fraction can be obtained from hydroxyl value.

### FLAXSEED

#### 28.154 ★ Oil by Refraction (44)—Official Final Action ★

(Note: Halogenated naphthalene may be harmful.  
Caution: See 51.084.)

# 29. Pesticide Residues

## MULTIRESIDUE METHODS

### GENERAL METHOD FOR ORGANOCHLORINE AND ORGANOPHOSPHORUS PESTICIDES (7)

29.001

#### Principle

Thoroughly mixed sample is extd with CH<sub>3</sub>CN (high-H<sub>2</sub>O foods) or aq. CH<sub>3</sub>CN (low-H<sub>2</sub>O or high sugar foods). Fat is extd from fatty foods and partitioned between pet ether and CH<sub>3</sub>CN. Aliquot (nonfatty samples) or entire soln (fatty samples) of CH<sub>3</sub>CN is dild with H<sub>2</sub>O and residues are extd into pet ether. Residues are purified by chromatgy on Florisil column, eluting with mixt. of pet and Et ethers. Residues in concd eluates are measured by GLC and identified by combinations of gas, thin layer, or paper chromatgy.

Analyst competence in applying method for trace residues should be assured before analysis. Recoveries of added compds thru method should be ≥80%.

Absence of interferences arising from laboratory and reagent contamination should also be assured by regular performance of reagent blanks. Solvs in particular, because of their concn during methods, can contribute significant interference if not sufficiently purified. Solvs of adequate purity are com. available from several manufacturers, but each batch must be tested under conditions of method in which it will be used.

Other reagents and app. (rubber, plastics, glass wool, etc.) are also potential source of interferences. See ref. (1) for recoveries obtained during collaborative and validation studies and Table 29:01 for commodities approved. See 29.008, introductory par., and 29.008(c) for GLC performance requirements:

**Table 29:01 Compounds and Crops to Which General Method Applies**

Compound	Official Final Action
Dieldrin Heptachlor epoxide	Group I nonfatty foods, dairy products, fish, vegetable oils, whole eggs
BHC p,p'-DDE p,p'-DDT p,p'-TDE(DDD)	
Lindane Methoxychlor Perthane	Group I nonfatty foods, dairy products, whole eggs
Aldrin Endrin Heptachlor Mirex	
o,p'-DDT	Group I nonfatty foods, dairy products
Diazinon Ethion Malathion Me parathion Parathion Ronnell	Group II nonfatty foods
Official First Action	
Polychlorinated biphenyls (PCB)	Poultry fat, fish, and dairy products

*Group I nonfatty foods:* apples\*, apricots, barley\*, beets, bell peppers, broccoli\*, cabbage\*, cantaloupes, cauliflower\*, celery, collard greens, corn meal and silage, cucumbers\*, eggplant, endive, grapes\*, green beans, hay, kale\*, mustard greens\*, oats\*, peaches, pears, peas, plums, popcorn, potatoes\*, radishes, radish tops, spinach, squash\*, strawberries, sugar beets, sweet potatoes, tomatoes\*, turnips\*, turnip greens\*, wheat\*

*Group II nonfatty foods:* Group I nonfatty foods marked with asterisk (\*) plus carrots, green peppers, and lettuce

sensitivity, sepn capability, and linearity. Behavior of >200 pesticides and industrial chems in method is given in JAOAC 61, 640(1978).

29.002

#### General Reagents

Solvs must be purified and final distn conducted in all-glass app. (Caution: See 51.011, 51.039, 51.040, 51.043, 51.054, 51.061, and 51.073.) See 29.001.

*Solvent purity test.*—Electron capture GLC requires absence of substances causing detector response as indicated by following test: Place 300 mL solv. in Kuderna-Danish concentrator fitted with 3-ball Snyder column and calibrated collection vessel, and evap. to 5 mL. Inject 5 µL conc. from 10 µL syringe into gas chromatograph, using conditions described in 29.008 (c). Conc. must not cause recorder deflection >1 mm from baseline for 2–60 min after injection.

(a) *Acetonitrile.*—See solv. purity test. Purify tech. CH<sub>3</sub>CN as follows: To 4 L CH<sub>3</sub>CN add 1 mL H<sub>3</sub>PO<sub>4</sub>, 30 g P<sub>2</sub>O<sub>5</sub>, and boiling chips, and distil in all-glass app. at 81–82°. Do not exceed 82°.

Some lots of reagent grade CH<sub>3</sub>CN are impure and require distn. Generally vapors from such lots will turn moistened red litmus paper blue when held over mouth of storage container. Pronounced amine odor is detectable.

(b) *Acetonitrile saturated with petroleum ether.*—Sat. CH<sub>3</sub>CN, (a), with redistd pet ether, (m).

(c) *Alcohol.*—USP, reagent grade, or MeOH, ACS.

(d) *Alcoholic alkali soln.*—2%. Dissolve 2 g NaOH or KOH in alcohol, and dil. to 100 mL.

(e) *Eluting solvent, 6%.*—Dil. 60 mL Et ether, (h), to 1 L with redistd pet ether, (m).

(f) *Eluting solvent, 15%.*—Prep. as in (e), using 150 mL Et ether.

(g) *Eluting solvent, 50%.*—Prep. as in (e), using 500 mL Et ether.

(h) *Ethyl ether.*—See solv. purity test. Redistd at 34–35°, and stored under N. Add 2% alcohol. Must be peroxide-free by test in *Definitions of Terms and Explanatory Notes*, item (3).

(i) *Florisil.*—60/100 PR grade, activated at 675°C (1250°F), available from Floridin Co. When 675°C activated Florisil is obtained in bulk, transfer immediately after opening to ca 500 mL (1 pt) glass jars, or bottles, with g-s or foil-lined, screw-top lids, and store in dark. Heat ≥5 hr at 130° before use. Store at 130° in g-s bottles or in air-tight desiccator at room temp. and rehear at 130° after 2 days.

Prep. mixed pesticide std soln in hexane contg 1, 4, 1, 2, 1, 2, and 4 µg/mL, resp., of ronnel, ethion, heptachlor epoxide, parathion, dieldrin, endrin, and malathion.

Test each batch of activated Florisil by placing 1 mL mixed pesticide std on prepd column and eluting as in *Cleanup*, 29.015. Conc. eluates from Florisil column to 10 mL. Inject aliquot (see 29.008) of each eluate into gas chromatograph and det. quant. recovery of each compd as in 29.018. Florisil that quant. elutes heptachlor epoxide, ronnel, and ethion in 6% eluate; dieldrin, endrin, and parathion in 15% eluate; and malathion in 50% eluate, is satisfactory.

Adsorptivity of lots of Florisil may be tested with lauric acid and size of column adjusted to compensate for variation in

adsorptivity (JAOAC 51, 29(1968)). Test adjusted column before use by performing elution test above.

(j) *Hexane*.—See *sol. purity test*. Reagent grade, redistd in all-glass app.

(k) *Magnesium oxide*.—Adsorptive magnesia (Fisher Scientific Co. No. S-120). Treat as follows: Slurry ca 500 g with H<sub>2</sub>O, heat on steam bath ca 30 min, and filter with suction. Dry overnight at 105–130° and pulverize to pass No. 60 sieve. Store in closed jar.

(l) *Magnesia-Celite mixture*.—Mix treated MgO, (k), with Celite 545, 1+1 by wt. Pet ether ext of Celite should be free of electron-capturing substances.

(m) *Petroleum ether*.—See *sol. purity test*. Reagent grade, redistd in all-glass app. at 30–60°.

(n) *Sodium sulfate*.—Anhyd., granular.

## 29.003

### Reagents for Thin Layer Chromatography

(a) *Aluminum oxide*.—Neutral Al<sub>2</sub>O<sub>3</sub> G (Type E, MC/B Manufacturing Chemists, Inc., No. 1090), or equiv., for TLC.

(b) *Developing solvents for organochlorine pesticides*.—(1) *n*-Heptane, com. grade. (2) *n*-Heptane contg 2% reagent grade acetone.

(c) *Chromogenic agent for organochlorine pesticides*.—Dissolve 0.100 g AgNO<sub>3</sub> in 1 mL H<sub>2</sub>O, add 20 mL 2-phenoxyethanol (Practical, Eastman Kodak Co.), dil. to 200 mL with acetone, add very small drop 30% H<sub>2</sub>O<sub>2</sub>, and mix. Store in dark overnight and decant into spray bottle. Discard after 4 days.

(d) *Developing solvents for organophosphorus pesticides*.—(1) *Immobilized*.—15 or 20% *N,N*-dimethylformamide (DMF) in ether. Dil. 75 or 100 mL DMF to 500 mL with ether and mix. (2) *Mobile*.—Methylcyclohexane.

(e) *Chromogenic agents for organophosphorus pesticides*.—(1) *Stock dye soln*.—Dissolve 1 g tetrabromophenolphthalein Et ester (Eastman No. 6810) in 100 mL acetone. (2) *Dye soln*.—Dil. 10 mL stock dye soln (1) to 50 mL with acetone. (3) *Silver nitrate soln*.—Dissolve 0.5 g AgNO<sub>3</sub> in 25 mL H<sub>2</sub>O and dil. to 100 mL with acetone. (4) *Citric acid soln*.—Dissolve 5 g granular citric acid in 50 mL H<sub>2</sub>O and dil. to 100 mL with acetone.

## 29.004 ★ Reagents for Paper Chromatography ★

(a) *Aqueous system*.—(1) *Immobilized solvents*.—Mineral oil, USP heavy (corn, cottonseed, tung, or soya oil may also be used). Dissolve 25 mL in Et ether and dil. to 500 mL. (2) *Mobile solvents*.—Acetone, 2-methoxyethanol (Me Cellosolve), or MeOH, dil. 75 mL to 100 mL with H<sub>2</sub>O; pyridine, dil. 40 mL to 100 mL with H<sub>2</sub>O.

(b) *Nonaqueous system*.—(1) *Immobilized solvents*.—Dil. 175 mL *N,N'*-dimethylformamide to 500 mL with Et ether; or dil. 50 mL 2-phenoxyethanol to 500 mL with ether. (2) *Mobile solvents*.—2,2,4-Trimethylpentane; mixed octanes.

(c) *Chromogenic agent*.—Place 1.7 g AgNO<sub>3</sub> in 200 mL vol. flask, dissolve in 5 mL H<sub>2</sub>O, add 10 mL 2-phenoxyethanol, and dil. to vol. with reagent grade acetone (add 1 small drop 30% H<sub>2</sub>O<sub>2</sub> soln to flask just before dilg to mark).

(d) *Pesticide std solns*.—1 mg/mL in EtOAc or hexane. (1  $\mu$ L = 1  $\mu$ g.)

## 29.005

### General Apparatus

(a) *High-speed blender*.—Waring Blendor, or equiv.

(b) *Chromatographic tubes*.—With Teflon stopcocks and coarse fritted plate or glass wool plug; 22 mm id  $\times$  300 mm.

(c) *Chromatographic tubes without stopcocks*.—22 mm id  $\times$  300 or 400 mm.

(d) *Filter tubes*.—Approx. 22 mm id  $\times$  200 mm with short delivery tube and coarse fritted plate or glass wool plug.

(e) *Kuderna-Danish concentrators*.—500 and 1000 mL with Snyder distilling column and 5 or 10 mL plain, vol., and graduated receiving flasks (Kontes Glass Co. No. K-570000, K-621400, and K-570050, or equiv.).

(f) *Separators*.—1000 and 125 mL with Teflon stopcocks.

(g) *Micro-Snyder column*.—2-ball (Kontes Glass Co. No. K-569001, or equiv.).

(h) *Micro-Vigreux column*.—Kontes Glass Co. No. K-569251, or equiv.

## 29.006

### Apparatus for Thin Layer Chromatography

(a) *Desaga/Brinkmann standard model applicator, or equiv.*

(b) *Desaga/Brinkmann standard mounting board, or equiv.*

(c) *Desaga/Brinkmann drying rack, or equiv*.—Accommodates ten 8  $\times$  8" plates.

(d) *Desaga/Brinkmann model 51 stainless steel desiccating cabinet, or equiv.*

(e) *Window glass*.—8  $\times$  8", double strength window glass plates of uniform width and thickness; smooth off corners and edges with file or other tool.

(f) *Chromatographic tank and accessories*.—Available from Arthur H. Thomas Co. No. 2749-F05, or equiv., with metal instead of glass troughs.

(g) *Dipping tank and accessories*.—Stainless steel, 8½  $\times$  8½  $\times$  ¼–¾/16" inside width with metal supports and close-fitting U-shaped cover ca 9  $\times$  ½". Capacity ca 300 mL (Arthur H. Thomas Co. No. 2749-H50, or equiv.).

(h) *Spotting pipets*.—1  $\mu$ L (Kontes Glass Co. No. K-422520).

(i) *Spray bottle*.—8 oz (Arthur H. Thomas Co. No. 2753-J10 or SGA Scientific, Inc., No. JC 2850, 250 mL).

(j) *Chromatography spray flask*.—250 mL (Microchemical Specialties Co., 1825 Eastshore Hwy, Berkeley, CA 94710, No. S-4530-D).

(k) *Tank liner*.—Cut 2 pieces, 12¼  $\times$  8¾", from desk blotter, white or colored, and bend into L-shape to fit tank.

## 29.007 ★ Apparatus for Paper Chromatography ★

(a) *Chromatographic chamber*.—For ascending chromatgy with 8  $\times$  8" sheets. Construct tanks, 9" long  $\times$  9" high  $\times$  3½" wide, from light stainless steel. From ¼" strips of the metal, form 2 supports and suspend flush with top from notches on sides at corners of tank. (Arthur H. Thomas Co. No. 2749-F10 has been found suitable.)

(b) *Pipets*.—Graduated 0.1 mL Mohr, and 1  $\mu$ L spotting pipet long enough to reach bottom of conical centr. tubes (Kontes Glass Co. No. K-422520).

(c) *Strong ultraviolet light source*.—Such as germicidal lamps (General Electric Co., Nela Park, Cleveland, OH 44112), either (1) two 30 watt, 36" tubes, No. G30T8, mounted in std 30 watt reflector fixture ca 20 cm above papers; or (2) two 15 watt, 18" tubes, No. G15T8, mounted in std 15 watt desk lamp fixture placed ca 10 cm above papers. Shield to protect eyes and skin at all times.

(d) *Chromatographic paper*.—Whatman No. 1, 8  $\times$  8" sheets. With hard pencil, rule origin line 2.5 cm from bottom edge and make dot at 8–10 evenly spaced positions, with end dots 2.5 cm from sides of paper. With pencil, mark test number or other identification below each dot. Wash papers for aq. systems several times with *distd* H<sub>2</sub>O and dry before use. (Papers for nonaq. systems need not be washed.) Any of following technics has been found satisfactory for washing papers:

(1) Hang paper clipped to glass rod in chromatgy tanks with lower edge in trough filled with *distd* H<sub>2</sub>O; when H<sub>2</sub>O rises to

★ Surplus method—see inside front cover.

top of paper, hang paper in hood and let dry. Repeat. Two papers may be clipped to each side of rod (4 papers per rod, 8 per tank).

(2) Wash by adaptation of continuous ascending paper chromatgy, using slit cover for box with 1 sheet per slit (JAOAC 40, 1013(1957)). Let washing continue overnight; air dry papers without removing from cover.

(3) Place 10–12 papers in shallow pan, cover with distd  $H_2O$ , and let soak ca 15 min; then carefully pour off  $H_2O$ . Repeat 8–10 times. Dry papers, and weight pile with glass plate during storage.

(4) Place 10–25 papers in inclined shallow pan and let distd  $H_2O$  run slowly in one end and out other 2–3 hr; dry papers.

(5) Place papers in 8¼" sq stainless steel funnel with 8" sq perforated removable plate at bottom, let soak in distd  $H_2O$  15–30 min, and drain off  $H_2O$  into suction flask; repeat several times, press papers between two 23 × 23 cm (9 × 9") glass or stainless steel plates, and dry overnight in forced-draft oven at 100–110°.

Paper, especially washed paper, must be dry. (All air-dried papers should be further dried 30 min at 100–110° before use.) If appreciable amt of moisture is in paper, it cannot absorb enough immobile solv. soln, and high  $R_f$  values result, as well as faint, indistinct chromatograms. Apparent air dryness is not enough; drying in forced-draft oven is necessary. Once dried, paper may be kept in ordinary dry storage without adverse result. This moisture effect is most critical with nonaq. systems.

## 29.008

### Apparatus for Gas Chromatography

(See also JAOAC 47, 326–342(1964); 49, 8–21(1966).)

Gas chromatgc system when operated with column, (b), and approx. conditions described in *Gas Chromatography*, 29.018, should be capable of producing ca ½ scale deflection for 1 ng heptachlor epoxide by electron capture detection and for 2 ng parathion by KCl-thermionic detection, and should resolve mixt. of heptachlor, aldrin, heptachlor epoxide, ethion, and carbo-phenthion into sep. peaks. Retention time for aldrin should be ca 4.5 min. Compds of interest must not be degraded by any part of GLC system.

(a) *Gas chromatograph*.—Instrument consisting of on-column injection system, all-glass column in oven controlled to  $\pm 0.1^\circ$ , electron capture and thermionic detectors, each with independent power supply, electrometer, and appropriate mv recorder.

(b) *Column*.—Glass, 1.85 m (6') × 4 mm id packed with 10% DC-200 (w/w) on solid support: (1) 80–100 mesh Chromosorb W HP (Johns-Manville Products Corp., manufacturer, but available thru many GLC distributors); (2) 80–100 mesh Gas-Chrom Q (Applied Science Laboratories, Inc.); (3) 80–90 mesh Anakrom ABS (Analabs, Inc.). DC-200 may be replaced by OV-101 (available from many GLC distributors).

Weigh 2 g Dow Corning 200 silicone fluid (12,500 centistokes) or OV-101 into beaker. Dissolve in  $CHCl_3$  and transfer to 300 mL Morton-type flask, using total of ca 100 mL  $CHCl_3$ . Add 18 g solid support, (1), (2) or (3), to flask. Swirl, and let stand ca 10 min. Place flask on rotary evaporator and remove solv. slowly with intermittent rotation, using 50°  $H_2O$  bath and slight vac. (Foaming may occur initially.) When solids appear damp, increase vac. Remove last traces of  $CHCl_3$  without rotation or by air drying. Use only free-flowing material to fill column. Use care at all stages of column prepn to prevent fracturing solid support. Condition column at 250–260° with N flow of ca 100 mL/min  $\geq 48$  hr or until endrin exhibits single peak.

(c) *Electron capture detector (ECD)*.—Concentric design, for use with dc voltage supply and  $^3H$  source (ca 150 mCi  $^3H$ , U.S. Nuclear Regulatory Commission license is required.)

Det. detector operating characteristics as follows: Apply dc voltage to detector. After system becomes stable (overnight), det. current-voltage relationship at various voltages between 200 and 0 v. (Current measurements at voltages of 200, 150, 100, 75, 50, 40, 30, 25, 20, 15, 10, 8, 6, 4, 2, and 1 provide points for smooth curve.) Slightly lower, stable, standing current may be obtained after detector has been at operating temp. several hr. This is probably due to loss of some easily removed radioactive material. Det. and plot response-voltage relationship at  $1 \times 10^{-9}$  amp full scale sensitivity for 1 ng injections of heptachlor epoxide at same voltages used in obtaining current-voltage curve. Select as operating voltage that voltage at which heptachlor epoxide causes ca 40–50% full scale recorder deflection. Check linearity of system from 0.2 to 2.0 ng heptachlor epoxide.

Other electron capture detectors may be substituted for dc voltage concentric design  $^3H$  detector, which is no longer marketed. Const current, variable frequency  $^{63}Ni$  electron capture detectors are acceptable substitutes when operated at conditions to produce stable, reproducible, linear responses. Optimum conditions may produce more sensitive response than from  $^3H$  detector. To maintain same method limit of quantitation of  $^3H$  detector, inject proportionately smaller equiv. sample wt into  $^{63}Ni$  detector system. The  $^{63}Ni$  electron capture detector may provide different relative responses for pesticides than those obtained with  $^3H$  electron capture detector. Use of  $Ar-CH_4$  carrier gas, as recommended for most  $^{63}Ni$  detectors, precludes use of KCITD dual detection system, (d), (h)–(j).

(d) *Potassium chloride thermionic detector (KCITD)*.—Flame ionization detector modified to incorporate coil with KCl coating prepd as in (1) or (2). Detector voltage is 300 v dc. Use in dual arrangement with electron capture detector.

All dual detector systems described are capable of comparable performance. In-series, (h), arrangement is preferred because of simplicity and ease of operation.

(1) *Coil with potassium chloride for in-series dual detector*.—See Fig. 29:01 (may be used with all detector arrangements). Wind Pt-Ir wire (B&S gage 26) on 7 mm diam. rod into 2 turn helix so that turns are touching. Approx. 5 mm below helix, continue to wind wire on 3 mm rod, or rod with same outside diam. as flame jet, making 3-turn spiral. Cut wire so that 7 mm helix is supported 4 mm above flame jet when 3 mm spiral is slipped over jet. Fill 30 mL tall-form Pt crucible ca ¼ full with KCl (ACS). Heat with Meker burner until all salt melts. Continue heating until bottom of crucible glows red, imparting pink glow to melt. Remove heat and begin dipping the 2-turn helix of coil into melt at 5 sec intervals as melt cools. (Make sure only 2-turn helix touches melt and do not raise coil above top of crucible.) When melt is at proper temp., salt clings to coil. Remove coil

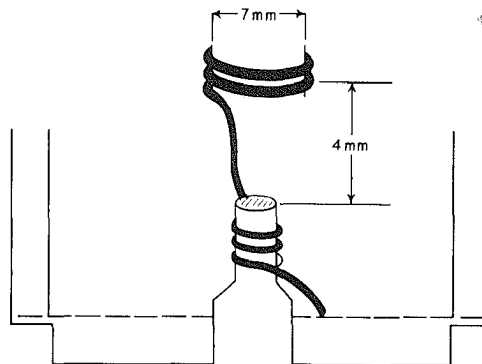

FIG. 29:01—KCl thermionic detector coil for in-series dual detection system

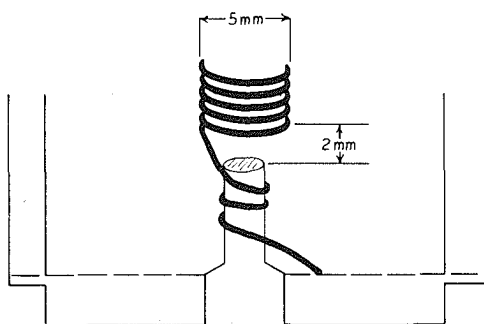

FIG. 29:02—KCl thermionic detector coil for parallel and in-series split dual detection systems

from melt. Place probe in center of coil while salt is molten. This causes crystn around probe tip. Remove center of coil. Remove any rough edges on coil coating by holding coil in burner flame 1 sec; id of properly coated coil is 5 mm. Position coil over flame jet.

(2) *Coil with potassium chloride for parallel and in-series split dual detectors.*—See Fig. 29:02. Wind Pt-Ir wire (B&S gage 26) on 5 mm diam. rod into 5-turn helix so that turns are close together or touching. Continue to wind wire on 3 mm rod, or rod having same outside diam. as flame jet, making 3-turn spiral. Cut wire so that 5 mm helix is supported 2 mm above flame jet when 3 mm spiral is slipped over jet. Grasp formed wire by end opposite 5 mm helix with forceps. Dip 5 mm helix into satd KCl (recrystd twice from H<sub>2</sub>O) soln, or apply KCl soln with dropper. Fuse in flame. (*Caution:* Use safety glasses; spattering occurs.) Repeat application of KCl soln 3–4 times until helix is coated with fused KCl. Coating should appear almost crystal clear. Position coil over flame jet.

(e) *Hydrogen.*—From generator or cylinder of compressed H gas (cylinder preferred). Equip cylinder with pressure drop of stainless steel capillary tubing (0.020" id) to restrict H flow to ca 30 mL/min at 20 lb delivery pressure. Place H source close to detector and use gas lines with min. dead vol. to reduce outgassing time in lines. (For fine precise control of H flow, insert Nupro Very Fine Metering Valve, "S" series (Nupro Co., 4800 E 345th Street, Willoughby, OH 44094; Part Number B-1S) between exit end of capillary tubing pressure drop and inlet of detector H line. *Caution:* Do not use Nupro valve as shut-off valve. Repeated tightening damages needle.) Use Swagelok fittings for all connections.

(f) *Air.*—Min. air requirement for thermionic detector is 300 mL/min. Cylinder of compressed air or aquarium air pump is recommended.

(g) *Capillary T-tube.*—(See Figs. 29:03 and 29:04.) Prep. 1:1 stream splitter (B) for parallel and in-series split dual detection systems. Fit two 4.5 cm lengths of stainless steel capillary tubing, 0.010" id, 1/16" od, into 1 cm length of std wall, 1/8" stainless steel tubing. Fit 1" length of No. 16 hypodermic tubing at right angles in hole drilled into the piece of 1/8" tubing. Silver braise all connections. Prep. capillary T-tube (E) for introducing purge gas to parallel system. Fit two 2.5 cm lengths of No. 16 hypodermic tubing into 1 cm length of std wall, 1/8" stainless

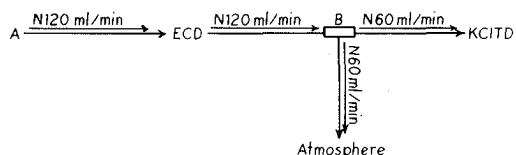

FIG. 29:03—In-series split dual detection system

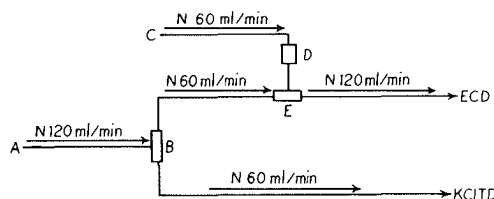

FIG. 29:04—Parallel dual detection system

steel tubing. Fit 1 cm length of No. 16 hypodermic tubing at right angles in hole drilled into piece of 1/8" tubing. Silver braise as above.

(h) *Assembly of in-series dual detection system.*—Assemble as in Fig. 29:05. Introduce column effluent (A) of 120 mL/min directly to ECD inlet. Connect ECD outlet directly to KCITD inlet, using No. 16 std wall Teflon tubing.

*Note:* For in-series, (h), and in-series split, (i), operation, thoroly check ECD for gas leaks, particularly at Teflon insulator.

(i) *Assembly of in-series split dual detection system.*—Assemble as in Fig. 29:03. Introduce column effluent (A) of 120 mL/min by passing thru 1:1 stream splitter (B) so that each detector receives 60 mL effluent/min. Increase flow to ECD by introducing 60 mL N/min from second N source (C) thru capillary T-tube (E). Preheat N from C by passing thru stainless steel capillary tube (D) (0.040" id) which extends 120 cm into column bath and returns to detector bath where addnl 35 cm of tubing is coiled into small helix. Connect capillary tubes and splitters to detectors with No. 16 std wall Teflon tubing. Measure flow at each end of splitter (B) to ensure exact 1:1 split.

(j) *Assembly of parallel dual detection system.*—Assemble as in Fig. 29:04. Split column effluent (A) of 120 mL/min by passing thru 1:1 stream splitter (B) so that each detector receives 60 mL effluent/min. Increase flow to ECD by introducing 60 mL N/min from second N source (C) thru capillary T-tube (E). Preheat N from C by passing thru stainless steel capillary tube (D) (0.040" id) which extends 120 cm into column bath and returns to detector bath where addnl 35 cm of tubing is coiled into small helix. Connect capillary tubes and splitters to detectors with No. 16 std wall Teflon tubing. Measure flow at each end of splitter (B) to ensure exact 1:1 split.

(k) *Potassium chloride thermionic detector operation.*—Zero recorder with zero control before detector flame is ignited (no signal). Turn on H (ca 30 mL/min) and ignite flame. Adjust H with flame burning to give baseline current (BLC) of  $0.2\text{--}0.8 \times 10^{-8}$  amp. (Sensitivity to P compds is directly related to KCl temp., which depends on H concn in flame.) Select operational electrometer setting and adjust H concn to obtain 40–50% full scale recorder deflection for 2 ng parathion entering detector. When baseline has stabilized, measure BLC precisely, at electrometer setting of  $1 \times 10^{-8}$  amp full scale. Return to operational electrometer setting and zero recorder pen, using current balance control to "buck out" current generated by detector. Check linearity of system from 0.4 to 4.0 ng parathion. Monitor BLC frequently during operation. If drift occurs, readjust H concn to maintain same BLC. *For accurate quantitation, BLC must be identical during chromatgy of sample and std.*

## Concentration Technics

### 29.009

### Purified Extracts

(Never evap. purified exts to dryness.)

(a) *To approximately 5 mL or more.*—Evap. on steam bath in Kuderna-Danish concentrator fitted with 3-ball Snyder column and vol. flask or graduated collection tube; 20-mesh boiling chip is necessary.

FIG. 29:05—In-series dual detection system

(b) *To less than 5 mL.*—Evap. to ca 5 mL as in (a). Remove collection tube from concentrator and fit tube with 2-ball micro-Snyder or micro-Vigreux column. Evap. to slightly less than desired vol., permit condensate to drain into tube, and remove column. Min. attainable vol. is 0.2–0.4 mL.

#### 29.010 *Extracts Containing Fats, Oils, or Plant Extractives*

(a) *Kuderna-Danish concentrator.*—Fitted with 3-ball Snyder column and vol. flask or graduated collection tube. Use on steam bath.

(b) *Flash evaporator.*—Keep flask in H<sub>2</sub>O bath at room temp.

(c) *Beaker.*—Evap. in beaker in H<sub>2</sub>O bath at 35–40° under stream of clean, dry air. Remove from heat and air stream as soon as last of solv. evaps. Let residual H<sub>2</sub>O evap. spontaneously. Solvs may be evapd from fats on steam bath for short periods.

#### Preparation of Sample and Extraction

##### 29.011 *Nonfatty Foods*

(Caution: See 51.004, 51.011, 51.039, 51.040, 51.043, and 51.073.)

Pit soft fruits, if necessary. Chop or blend representative sample of leafy or cole-type vegetables, pitted soft fruits, firm fruits, and roots. Mix thoroly to obtain homogeneous sample before taking portions for analysis. Grind dry or low moisture products, e.g., hays, to pass No. 20 sieve and mix thoroly. Proceed as in (a), (b), (c), or (d).

(a) *High moisture (more than 75% H<sub>2</sub>O) products containing less than 5% sugar.*—(1) *Products other than eggs.*—Weigh 100 g chopped or blended sample into high-speed blender jar, add 200 mL CH<sub>3</sub>CN and ca 10 g Celite, and blend 2 min at high speed. Filter with suction thru 12 cm buchner fitted with sharkskin paper into 500 mL suction flask. Transfer filtrate to 250 mL graduate and record vol. (F). Transfer measured filtrate to 1 L separator, and proceed as in (e). (2) *Whole eggs.*—Discard shells and blend combined yolks and whites at low speed ≥5 min or until sample is homogeneous. Low-speed blending will minimize foaming or "whipping" of sample. Weigh ≤25 g thoroly mixed yolks and whites into high-speed blender jar, and proceed with addn of CH<sub>3</sub>CN as in (1).

(b) *High moisture (more than 75% H<sub>2</sub>O) products containing 5–15% sugar.*—Add 200 mL CH<sub>3</sub>CN and 50 mL H<sub>2</sub>O to 100 g sample in blender and proceed as in (a). Transfer ≤250 mL filtered ext (record vol. (F)) to 1 L separator, and proceed as in (e).

(c) *High moisture (more than 75% H<sub>2</sub>O) products containing 15–30% sugar, e.g., grapes.*—Heat mixt. of 200 mL CH<sub>3</sub>CN and 50 mL H<sub>2</sub>O to 75°, add to 100 g sample in blender, and immediately proceed as in (a). Before filtered ext cools, transfer ≤250 mL (record vol. (F)) to 1 L separator. Let cool to room temp. and proceed as in (e).

(d) *Dry or low-moisture products, e.g., hays.*—Add 350 mL 35% H<sub>2</sub>O-CH<sub>3</sub>CN (350 mL H<sub>2</sub>O dild to 1 L with CH<sub>3</sub>CN) to 20–50 g ground sample in blender (if larger sample is required, add enough addnl extn mixt. to wet sample and permit thoro blending). (Caution: See 51.004 and 51.043.) Blend 5 min at high speed, and proceed as in (a), beginning "Filter with suction . . ." Transfer ≤250 mL filtered ext (record vol. (F)) to 1 L separator, and proceed as in (e).

(e) *Transfer of residues to petroleum ether.*—Carefully measure 100 mL pet ether and pour into separator contg filtrate. Shake vigorously 1–2 min and add 10 mL satd NaCl soln and 600 mL H<sub>2</sub>O. Hold separator in horizontal position and mix vigorously 30–45 sec. Let sep., discard aq. layer, and gently

wash solv. layer with two 100 mL portions H<sub>2</sub>O. Discard washings, transfer solv. layer to 100 mL g-s cylinder, and record vol. (P). Add ca 15 g anhyd. Na<sub>2</sub>SO<sub>4</sub> and shake vigorously. Do not let ext remain with Na<sub>2</sub>SO<sub>4</sub> >1 hr or losses of organochlorine pesticides by adsorption may result. Transfer soln directly to Florisil column, 29.015, or conc. to 5–10 mL in Kuderna-Danish concentrator for transfer.

(f) *Calculation for fruits and vegetables.*—Calc. g sample as  $S \times (F/T) \times (P/100)$ ; where  $S$  = g sample taken;  $F$  = vol. filtrate;  $T$  = total vol. (mL H<sub>2</sub>O in sample + mL CH<sub>3</sub>CN added – correction in mL for vol. contraction);  $P$  = mL pet ether ext; and 100 = mL pet ether into which residues were partitioned. When 50 mL H<sub>2</sub>O is added to CH<sub>3</sub>CN for extn of high sugar products, total vol.,  $T$ , is increased by 45, i.e.,  $T$  = 325 instead of 280 for samples contg 85% H<sub>2</sub>O.

*Example:* 100 g sample contains 85 g H<sub>2</sub>O; 200 mL CH<sub>3</sub>CN is added; vol. contraction is 5 mL. Total vol.,  $T$ , is 280 mL. If vol. filtrate is 235 mL, vol. pet ether ext is 85 mL, and residue is transferred to 100 mL pet ether, then  $100 \times (235/280) \times (85/100) = 71$  g sample.

Consult refs on food composition for av. H<sub>2</sub>O content. Water content of most fresh fruits and vegetables may be assumed to be 85%.

For 25 g whole eggs and 200 mL CH<sub>3</sub>CN, use 215 as  $T$ .

(g) *Calculation for dry or low moisture products, e.g., hays.*—Calc. g sample as in fruits and vegetables, (f), except  $T$  = total vol. (mL H<sub>2</sub>O in sample + mL 35% H<sub>2</sub>O-CH<sub>3</sub>CN added – correction in mL for vol. contraction). If H<sub>2</sub>O content of sample is ≤10%, disregard and use vol. of extg mixt. as  $T$ .

##### 29.012 *Fat-Containing Foods*

(After isolation of fat, proceed with CH<sub>3</sub>CN partitioning, 29.014.)

(a) *Animal and vegetable fats and oils.*—If solid, warm until liq. and filter thru dry filter.

(b) *Butter.*—Warm at ca 50° until fat seps and decant fat thru dry filter.

(c) *Milk.*—(Caution: See 51.011, 51.039, 51.054, and 51.073.) To 100 mL fluid milk (dil. evapd milk 1+1 with H<sub>2</sub>O) in 500 mL centrf. bottle, add 100 mL alcohol or MeOH and ca 1 g Na or K oxalate, and mix. Add 50 mL ether and shake vigorously 1 min; then add 50 mL pet ether and shake vigorously 1 min. Centrf. ca 5 min at ca 1500 rpm. Blow off solv. layer with wash bottle device, 16.220, Notes, into 1 L separator contg 500–600 mL H<sub>2</sub>O and 30 mL satd NaCl soln. Re-ext aq. residue twice, shaking vigorously with 50 mL portions ether-pet ether (1+1); centrf. and blow off solv. layer into separator after each extn. Mix combined exts and H<sub>2</sub>O cautiously. Drain and discard H<sub>2</sub>O. Rewash solv. layer twice with 100 mL portions H<sub>2</sub>O, discarding H<sub>2</sub>O each time. (If emulsions form, add ca 5 mL satd NaCl soln to solv. layer or include with H<sub>2</sub>O wash.) Pass ether soln thru column of anhyd. Na<sub>2</sub>SO<sub>4</sub>, 50 × 25 mm od, and collect eluate in 400 mL beaker. Wash column with small portions pet ether and evap. solv. from combined exts at steam bath temp. under air current to obtain fat.

(d) *Cheese.*—Place 25–100 g (to provide 3 g fat) diced sample, ca 2 g Na or K oxalate, and 100 mL alcohol or MeOH in high-speed blender and blend 2–3 min. (If experience with product indicates emulsions will not be broken by centrfg, add 1 mL H<sub>2</sub>O/2 g sample before blending.) Pour into 500 mL centrf. bottle, add 50 mL ether, and shake vigorously 1 min; then add 50 mL pet ether and shake vigorously 1 min (or divide between two 250 mL bottles and ext each by shaking vigorously 1 min with 25 mL each ether). Proceed as in (c), beginning "Centrf. ca 5 min at ca 1500 rpm."

**(e) Fish.**—(Caution: See 51.004, 51.011, 51.039, and 51.073.)

Weigh 25–50 g thoroly ground and mixed sample into high-speed blender. (If fat content is known or can be estd, adjust sample size so that max. of ca 3 g fat will be extd.) Add 100 g anhyd.  $\text{Na}_2\text{SO}_4$  to combine with  $\text{H}_2\text{O}$  present and disintegrate sample. Alternately blend and mix with spatula until sample and  $\text{Na}_2\text{SO}_4$  are well mixed. Scrape down sides of blender jar and break up caked material with spatula. Add 150 mL pet ether and blend at high speed 2 min. Decant supernate pet ether thru 12 cm buchner, fitted with 2 sharkskin papers, into 500 mL suction flask. Scrape down sides of blender jar and break up caked material with spatula. Re-ext residue in blender jar with two 100 mL portions pet ether and blend 2 min each time. (After blending 1 min, stop blender, scrape down sides of blender jar, and break up caked material with spatula; continue blending 1 min.) Scrape down sides of blender jar and break up caked material between extns. Decant supernate pet ether from repeat blendings thru buchner and combine with first ext. After last blending, transfer residue from blender jar to buchner, and rinse blender jar and material in buchner with three 25–50 mL portions pet ether. Immediately after last rinse, press residue in buchner with bottom of beaker to force out remaining pet ether. Pour combined exts thru  $40 \times 25$  mm od column of anhyd.  $\text{Na}_2\text{SO}_4$  and collect eluate in 500 or 1000 mL Kuderna-Danish concentrator with plain tube. Wash flask and column with small portions pet ether and evap. most of pet ether from combined exts and rinses in Kuderna-Danish concentrator. Transfer fat soln to tared beaker, using small amts pet ether. Evap. pet ether at steam bath temp. under current of dry air to obtain fat. When pet ether is completely removed, weigh and record wt of fat extd.

Record wt of fat taken for cleanup. ((Wt fat for cleanup/wt fat extd)  $\times$  wt original sample = wt sample analyzed.) If it is known that  $\leq 3$  g fat will be extd from particular sample, do not isolate and weigh fat before  $\text{CH}_3\text{CN}$  partitioning. Detn is then on basis of wt of original sample.

Proceed as in general method, 29.001–29.028, beginning with 29.014.

**29.013****Soil (2)**

(Official Final Action for aldrin, *p,p'*-DDE, *o,p'*-DDT, *p,p'*-DDT, dieldrin, endrin, heptachlor, heptachlor epoxide, lindane, and *p,p'*-TDE (DDD))

Weigh 10.0 g undried soil, sieved thru 2 mm sieve and mixed thoroly, into 250 mL erlenmeyer. Add 7 mL 0.2M  $\text{NH}_4\text{Cl}$  soln (10.7 g/L) and let stand 15 min. Add 100 mL hexane-acetone (1+1), stopper tightly, and shake overnight ( $\geq 12$  hr) on reciprocal or wrist-action shaker at 180 rpm.

Carefully pour supernate, avoiding aq.-clay phase, thru 2–3 cm column (22 mm id) of Florisil, 29.002(i), and collect eluate in 1 L separator. Rinse flask and soil with two 25 mL portions hexane-acetone and decant thru column. Rinse column with 10 mL hexane-acetone.

Add 200 mL  $\text{H}_2\text{O}$  to separator and shake gently ca 30 sec. Drain aq. phase into second separator and ext with 50 mL hexane. Combine hexane layers in first separator and wash with 100 mL  $\text{H}_2\text{O}$ . Drain and discard  $\text{H}_2\text{O}$ . Pour hexane thru 2 cm column (22 mm id)  $\text{Na}_2\text{SO}_4$ , conc. to 100 mL, and make preliminary injection of 5–10  $\mu\text{L}$  into gas chromatograph. If peaks are present at retention times of DDE or dieldrin, conc. to 10 mL in Kuderna-Danish concentrator, 29.010(a), and sep. DDE or dieldrin as in 29.015. (This cleanup may also be necessary with exts from high org. matter soils.) Proceed as in 29.018, using ECD, (b). To calc. to dry basis, dry sep. sample of 10 g ca 16 hr at  $105^\circ$  to obtain % solids.

**Cleanup Technics****29.014****Acetonitrile Partitioning**

(Caution: See 51.011, 51.039, and 51.073. Different fats and oils may show varying tendencies to emulsion formation.)

Weigh  $\leq 3$  g fat into 125 mL separator, and add pet ether so that total vol. of fat and pet ether is 15 mL. Add 30 mL  $\text{CH}_3\text{CN}$  satd with pet ether, 29.002(b), shake vigorously 1 min, let layers sep., and drain  $\text{CH}_3\text{CN}$  into 1 L separator contg 650 mL  $\text{H}_2\text{O}$ , 40 mL satd  $\text{NaCl}$  soln, and 100 mL pet ether. Ext pet ether soln in 125 mL separator with 3 addnl 30 mL portions  $\text{CH}_3\text{CN}$  satd with pet ether, shaking vigorously 1 min each time. Combine all exts in the 1 L separator.

(If experience with particular sample (e.g., fish) indicates that cleanup may not be sufficient, perform partitioning as follows: Drain  $\text{CH}_3\text{CN}$  phase from first partitioning into second 125 mL separator contg 15 mL pet ether, shake vigorously 1 min, let layers sep., and drain  $\text{CH}_3\text{CN}$  into 1 L separator contg 650 mL  $\text{H}_2\text{O}$ , 40 mL satd  $\text{NaCl}$  soln, and 100 mL pet ether. Pass  $\text{CH}_3\text{CN}$  phase from each of 3 addnl partitionings thru same 15 mL pet ether in 125 mL separator. Shake vigorously each time and combine  $\text{CH}_3\text{CN}$  exts in the 1 L separator.)

Hold separator in horizontal position and mix thoroly 30–45 sec. Let layers sep. and drain aq. layer into second 1 L separator. Add 100 mL pet ether to second separator, shake vigorously 15 sec, and let layers sep. Discard aq. layer, combine pet ether with that in original separator, and wash with two 100 mL portions  $\text{H}_2\text{O}$ . Discard washings and draw off pet ether layer thru  $50 \times 25$  mm od column of anhyd.  $\text{Na}_2\text{SO}_4$  into 500 mL Kuderna-Danish concentrator. Rinse separator and then column with three ca 10 mL portions pet ether. Evap. combined ext and rinses to ca 10 mL in Kuderna-Danish concentrator for transfer to Florisil column.

**29.015****Florisil Cleanup**

(Caution: See 51.011, 51.039, 51.040, 51.054, and 51.073.)

Prep. 22 mm id Florisil column, 29.005(b), contg 10 cm, after settling (or amt detd by lauric acid test, 29.002(i)), of activated Florisil topped with ca 1 cm anhyd.  $\text{Na}_2\text{SO}_4$ . Prewet column with 40–50 mL pet ether. Place Kuderna-Danish concentrator with vol. flask or graduated collection flask under column to receive eluate. Transfer pet ether ext or conc. to column, letting it pass thru at  $\leq 5$  mL/min. Rinse containers and  $\text{Na}_2\text{SO}_4$ , if present, with two ca 5 mL portions pet ether, pour rinsings onto column, rinse walls of tube with addnl small portions pet ether, and elute at ca 5 mL/min with 200 mL 6% eluting solv., 29.002(e). Change receivers and elute with 200 mL 15% eluting solv., 29.002(f), at ca 5 mL/min. Change receivers and elute with 200 mL 50% eluting solv., 29.002(g), at ca 5 mL/min.

Conc. each eluate to suitable definite vol. in Kuderna-Danish concentrator. When vol.  $< 5$  mL is needed, use 2-ball micro-Snyder or micro-Vigreux column.

First eluate (6%) contains *organochlorine pesticides* (aldrin, BHC, DDE, DDD (TDE), *o,p'*- and *p,p'*-DDT, heptachlor, heptachlor epoxide, lindane, methoxychlor, mirex, and Perthane), *industrial chems* (polychlorinated biphenyls (PCB)), and *organophosphorus pesticides* (ethion and ronnel) and is usually suitable for GLC directly. If further cleanup is necessary, repeat Florisil cleanup, using new column. Second eluate (15%) contains *organochlorine pesticides* (dieldrin and endrin) and *organophosphorus pesticides* (Diazinon, Me parathion, and parathion). If further cleanup is necessary, det. organophosphorus pesticides by GLC or TLC; then proceed with *Magnesia Cleanup*, 29.016, and/or *Saponification*, 29.017, which are applicable only

to organochlorine pesticides in 15% eluate (organophosphorus pesticides are degraded). Third eluate (50%) contains *organophosphorus pesticide* malathion.

**29.016****Magnesia Cleanup**

(Applicable only to organochlorine pesticides in 15% eluate when addnl cleanup is necessary)

Transfer ca 10 g MgO-Celite mixt., **29.002(i)**, to chromatgc tube without stopcock, **29.005(c)**, using vac. to pack. Prewash with ca 40 mL pet ether, discard prewash, and place Kuderna-Danish concentrator under column. Transfer 15% Florisil eluate, concd to ca 5 mL, to column, rinsing with small portions pet ether. Force pet ether into column with slight vac. or pressure. Then elute with 100 mL pet ether. Conc. eluate to suitable vol. Proceed with detn, or saponification, if required.

**29.017****Saponification**

(Applicable only to organochlorine pesticides in 15% eluate if MgO-Celite eluate is not substantially free from oily materials.)

Transfer concd eluate to 125 mL g-s flask, rinsing with pet ether, and evap. just to dryness. Add 20 mL 2% alc. NaOH or KOH, **29.002(d)**, and reflux 30 min under air condenser. Transfer to 125 mL separator and rinse flask with three 10 mL portions pet ether, transferring each to separator. Add 20 mL H<sub>2</sub>O and shake vigorously. Drain aq. layer into second separator contg 20 mL pet ether, shake vigorously, let sep., discard aq. layer, and add pet ether to first separator. Wash combined pet ether exts with three 20 mL portions aq. alcohol (1+1). (If initial aq. alcohol wash causes heavy emulsions, use H<sub>2</sub>O only for addnl washes.) Discard aq. alcohol and dry pet ether layer thru 50 × 25 mm od column of anhyd. Na<sub>2</sub>SO<sub>4</sub>, rinsing with pet ether. Conc. solv., and rechromatograph on MgO-Celite column.

**Detection Methods****29.018****Gas Chromatography—Tentative Identification and Quantitative Measurement**

(Applicable to organochlorine pesticides, organophosphorus pesticides, and polychlorinated biphenyls (PCB). Method is applicable to PCB residues when present alone in sample. If pesticidal or other compds are detected in chromatogram of the PCB residue, other chemical or physical operations must be applied to eliminate or minimize their interference before PCB quantitation.)

Inject suitable aliquot (3–8  $\mu$ L) of concd eluate from Florisil or MgO-Celite column contg amt of compd within linear range into gas chromatograph, **29.008**, using 10  $\mu$ L syringe. Tentatively identify residue peaks on basis of retention times. Measure area or ht of residue peak(s) and det. residue amt by comparison to peak area or ht obtained from known amt of appropriate ref. material(s). To ensure valid measurement of residue amt, size of peaks from residue and ref. std should be within  $\pm 25\%$ . Chromatograph ref. material(s) immediately after sample.

Measure PCB residues by comparing total area or ht of residue peaks to total area or ht of peaks from appropriate Aroclor(s) (Analabs, Inc.) ref. materials. Measure total area or ht response from common baseline under all peaks. Use only those peaks from sample that can be attributed to chlorobiphenyls. These peaks must also be present in chromatogram of ref. material. Mixt. of Aroclors may be required to provide best match of GLC patterns of sample and ref.

Alternatively, det. PCB residues by individual peak area comparisons using Aroclor ref. material wt factors in Table **29.02**. Calc. each PCB peak against appropriate individual ref. peak with exactly same absolute retention. Sum individual peak values to obtain total ppm PCB. (This method is recommended

for PCB residues with chromatgc patterns which are altered extensively from that of any Aroclor ref.)

(a) *Recommended operating conditions for 10% DC-200 or OV-101 column.*—Glass column, 1.8 m (6') × 4 mm id. Temps ( $^{\circ}$ ): injector, 225; column 200; <sup>3</sup>H electron capture detector, 210 max.; carrier gas flow, 120 mL N/min.

(b) *Electron capture detection (ECD).*—(Use for detn of organochlorine pesticides in fruits, vegetables, and food contg fats and for detn of PCB in foods and paperboard.) Select for <sup>3</sup>H electron capture detector operating voltage that voltage (ca 50 v dc) at which 1 ng heptachlor epoxide produces 40–50% full scale recorder deflection at 1 or 3 × 10<sup>-9</sup> amp full scale sensitivity.

Operate <sup>63</sup>Ni electron capture detector to produce stable, reproducible, linear response, and adjust amt of injected sample to accommodate differences in instrument sensitivity.

(c) *Potassium chloride thermionic and electron capture dual detection.*—(Use one of the 3 dual detection systems specified in **29.008(h)**, (i), (j), for detn of organophosphorus and organochlorine pesticides and PCB. In-series system, (h), is preferred because of simplicity and ease of operation.) (1) *In-series dual detection.*—Operate ECD as in (b). For KCITD, adjust H flow producing 0.2–0.8 × 10<sup>-8</sup> amp baseline current and select electrometer setting at which 2 ng parathion produces 40–50% full scale recorder deflection. (2) *In-series split dual detection.*—Same as (3), *Parallel*, except ECD receives entire injection and KCITD receives 1/2 amt injected into column. (3) *Parallel dual detection.*—Same as (1), *In-series dual*, except column effluent is split; therefore, inject twice as much sample to obtain desired limit of quantitation.

**Table 29.02 Weight % factors for individual gas chromatographic peaks in Aroclor reference materials. Peaks are identified by their retention time relative to *p,p'*-DDE=100 at conditions consistent with 29.018(a) and (b).**

<sup>a</sup> Food and Drug Administration Lot Nos. (Wt factors are valid only for these FDA Lot Nos.) Aroclor ref. materials are available from Food and Drug Administration, Division of Chemical Technology, HFF-420, 200 C St SW, Washington, DC 20204.

## Thin Layer Chromatography—Confirmation of Identity

## Method I

(Applicable to organochlorine and organophosphorus pesticides except where indicated)

## 29.019

## Preparation of Adsorbent Layer

Before coating, wash plates in hot soapy water and thoroughly rinse with distilled H<sub>2</sub>O. Press plates snugly into position on mounting board that has retaining ledge on one side and one end. Plastic board is mounted so that long side with raised ledge faces operator while short side with ledge is to right of operator. Before coating, wipe plates with few mL alcohol. Position applicator, trough open, with left edge 6 mm in from edge of first plate to be coated.

To coat 5 plates, weigh 30 g Al<sub>2</sub>O<sub>3</sub> G, 29.003(a), into 250 mL Erlenmeyer. Add 50 mL H<sub>2</sub>O, stopper, and shake moderately 45 sec. Violent shaking produces bubbles, resulting in "pock-marked" layer.

*Suspensions that contain adsorbents with binders set rapidly, and entire operation from prep of slurry to final coating must be completed within 2 min.*

After shaking, immediately pour slurry into applicator chamber. Rotate chamber by turning large lever handle thru 180°. After few sec, slurry begins to flow out of exit slit. Grasp applicator with both hands and pull it manually with steady motion across series of plates. Approx. 5 sec is required for actual coating operation. Immediately after application, tap edge of mounting board or shake entire board gently to smooth out slight ripples or imperfections in wet coating.

Let coated plates dry in position on mounting board 15 min. Then dry plates in forced-draft oven 30 min at 80°. Remove plates and cool.

Examine plates carefully in transmitted and reflected light for imperfections or irregularities in coating. Discard any plates showing extensive rippling or mottling of layer.

Prep. 5 more plates while first set is drying. Be sure applicator is thoroughly cleaned and dried before reusing. The 10 coated and dried plates may be prewashed immediately.

## 29.020

## Prewashing of Adsorbent Layer

Scrape 1 cm of adsorbent off edge of plate with razor blade. Pour 15 mL 50% aq. acetone into metal trough inside chromatgc tank. Cut out 2 × 20 cm strip of Whatman No. 1 filter paper, wet with solv., and place over scraped off portion with 6 mm overlapping adsorbent layer. Place plate in chromatgc tank, seal tank with masking tape, and develop with 50% aq. acetone to within 4 cm from top of plate (75–90 min). Remove plate from tank, remove filter paper wick, invert plate, and dry in hood 5 min. Dry plate 45 min at 80°. Remove plate from oven, cool, and store in desiccator. Use prepd plates within 1 week after prepn.

## 29.021

## Sample Spotting

Make pencil mark 4 cm from bottom of plate at both sides. Imaginary line between the two points indicates sample spotting or origin "line." Draw line (which removes coating) completely across plate 14 cm from bottom edge; this line represents solv. front after development. On lower edge of adsorbent starting 2 cm in from left edge of plate, make 18 marks with pencil at 1 cm intervals. (Fewer marks with longer intervals may be used, if desired. Marks serve as horizontal guides to sample application. Identity of samples and stds may be etched directly into adsorbent layer above these marks above solv. front line.)

Imaginary spotting "line" is actually shadow line cast by strong light source from wooden ruler supported 2 cm above plate. Align ruler shadow on the two 4 cm marks on either edge

of plate. Shadow line and 18 marks, resp., serve as vertical and horizontal guides for sample application.

For optimum semiquant. detn, spot aliquot of sample as follows:

(a) *Organochlorine pesticides*.—Adjust aliquot to give residue spot within range 0.005–0.1 µg. Spot stds and std mixts at 0.002, 0.005, 0.01, 0.02, 0.05, 0.1, and 0.2 µg. Sample spots >0.2 µg are difficult to det. quant. and <0.005 µg may be difficult to distinguish. Spot all 6% Florisil eluates on one plate and 15% Florisil eluates on another plate.

(b) *Organophosphorus pesticides*.—Adjust aliquots of sample and stds to give spot within range 0.1–0.5 µg. Spot 6, 15, and 50% Florisil eluates on same plate. Ronnel and ethion are not resolved; spot each std sep. Spot Diazinon, Me parathion, and malathion sep. or as mixt.

Vol. of sample ext spotted should be ≤10 µL, if possible, and spotting should be done repeatedly with 1, 2, or 3 µL Kontes spotting pipet. Spot std and sample solns with same pipet. For best results, keep size of spotted samples as small as possible.

## 29.022

## Development

(a) *Organochlorine pesticides*.—Place liners and metal trough in tank, 29.006(f). Presat. liner by pouring 75 mL developing solv., 29.003(b), into bottom of tank ≥30 min before developing plate. Presatn decreases development time and improves uniformity of *R<sub>f</sub>* values.

For plates spotted with 6% Florisil eluates, pour 50 mL *n*-heptane into trough. Place lower edge of plate in metal trough with top of plate leaning against side of tank. Place glass cover plate on tank and seal with masking tape.

For plates spotted with 15% Florisil eluates, use acetone-*n*-heptane (2+98) as developing solv.

(b) *Organophosphorus pesticides*.—Prep. chromatgc tank, 29.006(f), after samples and stds have been spotted on plate. Place liners and metal trough in tank. Pour 50 mL methylcyclohexane, 29.003(d)(2), into trough, and 75 mL into bottom of tank. Quickly fill dipping tank, 29.006(g), to within 4–5 cm from top with immobile solv., 29.003(d)(1). Invert plate and dip with uncoated side touching back wall of tank to prevent front wall from scraping the adsorbent layer during dipping operation. Dip plate just to spotting line, remove, and immediately place in metal trough, with top portion of plate leaning against side of tank. Place glass cover plate on tank and seal with masking tape.

When solv. front in (a) or (b) just reaches pencil line 10 cm above spotting "line," remove plate and dry in hood 5 min.

## 29.023

## Spraying

(Caution: See 51.017.)

(a) *Organochlorine pesticides*.—Support plate on one side and spray fairly heavily with chromogenic agent, 29.003(c), using lateral motions of spray bottle perpendicular to direction of solv. flow. Spray until plate appears translucent or soaked with reagent. Underspraying will result in poor sensitivity. After spraying, dry plate in hood 15 min; then immediately place under UV light source and proceed as in 29.024.

(b) *Organophosphorus pesticides*.—Immediately spray plate moderately heavily and uniformly with dye soln, 29.003(e)(2), using lateral motions of spray flask, 29.006(j), perpendicular to direction of solv. flow. Plate should be vivid blue after spraying. Using spray bottle, 29.006(i), overspray plate lightly and uniformly with AgNO<sub>3</sub> soln, 29.003(e)(3) (at this point plate should be bluish purple and spots should be discernible).

After 2 min, overspray plate moderately and uniformly with citric acid soln, 29.003(e)(4), using spray bottle, 29.006(i). After spraying, thiophosphate pesticides should immediately appear

as vivid blue or purple spots against yellow background. Color of spots reaches max. intensity ca 5–10 min after citric acid spraying. After ca 10 min, background begins to change from yellow to greenish blue, masking spots. At this point, respraying plate with citric acid soln changes background back to yellow and makes spots stand out as well as or better than originally. Evaluate chromatogram  $\leq 10$  min after respraying. Blue spots fade completely and irreversibly after 30–40 min from time of original citric acid spraying.

**29.024****Exposure**

(Caution: See 51.016.)

Expose plate to UV light until spot for std of lowest concn appears; 5 ng of most organochlorine pesticides should be visible after 15–20 min exposure with equipment described under 29.007(c). Exposure times >30 min will not harm plates. For best results, place plates 8 cm from bottom edge of lamps.

**Method II**

(Applicable only to organochlorine pesticides)

**29.025****Preparation of Adsorbent Layer**

Weigh 40 g  $Al_2O_3$  G, 29.003(a), into 500 mL centr. bottle. Add 80 mL 0.2%  $HNO_3$ , shake well, and centr. at ca 1200 rpm 1–2 min. Decant supernate into 100 mL graduate, and record vol. (35–40 mL should be recovered). Add 80 mL  $H_2O$ , breaking up material on bottom of centr. bottle with glass rod, if necessary. Shake well and centr. as before. Decant and record vol. supernate recovered (60–70 mL). Add 2 addnl 80 mL portions  $H_2O$ , shake well, centr., and decant.

Weigh the  $Al_2O_3$  and  $H_2O$  that has been retained. (Wt should be ca 100 g.) Add 10 mL 1%  $AgNO_3$  soln and enough  $H_2O$  to make total wt 120–130 g. Shake well, place in applicator, and prep. plates as in 29.019. Let plates air dry in position on mounting board 15 min. Place in metal drying rack, in vertical position, 30 min at 100°.

**29.026****Sample Spotting**

Spot as in 29.021. Draw line across plate 4 cm from top (which removes coating). Next, scrape 6 mm of coating from each side of plate. (Irregularities in thickness of coating on these outer edges cause uneven flow of mobile solv.) Make pencil mark at each side of layer 2.5 cm from bottom of plate; imaginary line between these 2 points indicates sample spotting line. Spot samples and stds at 1 cm intervals.

**29.027****Development and Exposure of Plates**

(Caution: See 51.016.)

Develop plates as in 29.022, except use only 25–30 mL mobile solv. in trough, since spotting line has been lowered to 2.5 cm. Use *n*-heptane to develop 6% Florisil eluates, and acetone-*n*-heptane (2+98) for 15% Florisil eluates.

Plates may be exposed to UV light after short drying period (ca 5 min) after removal from tank. Spots of aldrin, DDE, and isomers of DDT will appear within 5–10 min after exposure; lindane, endrin, dieldrin, and all others will require more time. Plates may be exposed 1.5–2 hr without appreciable darkening of background.

**★ Paper Chromatography ★****29.028****Technic (3)**

(Once paper chromatg is started, spot, develop, spray with chromogenic agent, and expose to UV light without delay; do not interrupt overnight. Caution: See 51.016.)

Transfer 10 mL aliquot from column cleanup to 15 mL conical centr. tube. (With most pesticides upper limit for good spots is ca 10  $\mu$ g and optimum is ca 2  $\mu$ g.) Evap. under gentle air stream at room temp. just to dryness (Caution). Wash down sides of tube with 0.5 mL ether, evap., and again wash down with 0.1–0.2 mL ether. Evap., take up residue (usually not visible) with 0.03–0.04 mL ether, and transfer to one of dots on origin line of chromatogram, 29.007(d), using 1  $\mu$ L pipet repeatedly, until all residue is placed on 1 spot. Let spot dry after each application to restrict its size. Wash tube again with 0.03–0.04 mL ether and transfer to same spot.

Transfer std solns of known pesticides to other dots on same paper, adjacent to sample spots. (1 full  $\mu$ L pipet contains 1  $\mu$ g compd. Use addnl pipetfuls to increase amt of pesticide on 1 spot.) For identification place several compds on sep. dots on same paper as unknown. For semiquant. estn place different amts of same compd, varying by 1–2  $\mu$ g intervals, on sep. dots. (Experience and preceding analyses are guide to pesticide residues to be expected and thus to choice of pesticides to be used as stds for identification. If  $R_f$  values differ enough, several different pesticides may be placed on same dot; use 2–5  $\mu$ g per pesticide.)

After samples and stds are spotted on paper, put 50 mL mobile solv. in trough; then fill dipping tank, 29.006 (g), with immobile solv. Hold paper by bottom, using spring clip, immerse it top down into soln of immobile solv. just to origin line, and immediately remove it. For aq. system, hang paper to dry 2–3 min; while paper is drying, clip glass rod, which supports paper in tank, to top of paper (opposite origin line). In nonaq. system, when paper is dipped in immobile solv., place in mobile solv. in chromatgc tanks as quickly as possible, allowing no time for drying. (As ether evaps, it may condense moisture on paper, which interferes with ability of pesticides to dissolve in immobile solv. Excessive humidity and temp. tend to result in high  $R_f$  values and faint, indistinct chromatograms.) Hang paper in tank so that origin end dips ca 1 cm into trough filled with mobile solv. Place glass plate on top of tank and seal with masking tape.

When mobile solv. has risen thru paper to within 2.5 cm of top (1.5–4 hr, depending on solv. system used), unseal tank, mark solv. front, and hang paper up until it appears dry. Uniformly spray dry paper with chromogenic agent (do not spray so heavily that it runs down paper). Dry paper until most of solv. is removed, and expose both sides to UV light until reduced Ag spots are developed. (Darkening of chromatogram background during storage may be largely prevented by washing finished chromatogram, after exposure to UV light, as follows: Suspend paper from glass rod with 3 or 4 clips, and thoroly play gentle stream of distd  $H_2O$  on both sides of sheet. Let suspended papers hang until dry (papers are very fragile when wet).)

It is advisable to evaluate chromatograms before washing them. Compare location, size, and intensity of spots from unknown with those from stds for identification and semiquant. estn of pesticides. Always chromatograph knowns and unknowns on same paper.

### Endosulfan, Endosulfan Sulfate, Tetradifon, and Tetrasul (4)—Official Final Action

(Applicable to apples and cucumbers)

#### 29.029

#### Principle

Pesticides are extd with  $\text{CH}_3\text{CN}$ , partitioned with pet ether, eluted thru Florisil column with mixts of  $\text{CH}_2\text{Cl}_2$ , hexane, and  $\text{CH}_3\text{CN}$ , and detd by gas chromatgy. Method is variation of 29.001–29.018, as it applies to nonfatty foods. Pesticides are eluted from Florisil column with different eluants to improve cleanup for these compds.

#### 29.030

#### Apparatus

See 29.005(a)–(h) and 29.008(a)–(c).

#### 29.031

#### Reagents

- (a) *Florisil*.—See 29.002(i).  
 (b) *Solvents*.—Hexane,  $\text{CH}_2\text{Cl}_2$ , and  $\text{CH}_3\text{CN}$ , all distd in glass and free from electron capturing substances (see 29.002).  
 (c) *Eluant mixtures*.—(1) *Eluant I*.—20%  $\text{CH}_2\text{Cl}_2$ -hexane. Dil. 200 mL  $\text{CH}_2\text{Cl}_2$  with hexane. Let mixt. reach room temp. and adjust vol. to 1 L with hexane. (2) *Eluant II*.—50%  $\text{CH}_2\text{Cl}_2$ -0.35%  $\text{CH}_3\text{CN}$ -49.65% hexane. Pipet 3.5 mL  $\text{CH}_3\text{CN}$  into 500 mL  $\text{CH}_2\text{Cl}_2$ , and dil. with hexane. Let mixt. reach room temp. and adjust to 1 L with hexane.

#### 29.032

#### Preparation of Sample and Extraction

See 29.011(a), (b), (e)–(g).

#### 29.033

#### Column Chromatography

[Caution: See 51.011, 51.043, and 51.061.]

Add wt activated Florisil detd from lauric acid absorption value, 29.002(i), to 22 mm id chromatgc tube, 29.005(b). Gently tap chromatgc column to settle Florisil. Top column with ca 12 mm anhyd. granular  $\text{Na}_2\text{SO}_4$ . Wet column with 40–50 mL hexane. Use Kuderna-Danish concentrator with volumetric or graduated tube to collect eluate. Transfer pet ether or hexane soln of sample ext to column, and let it elute at ca 5 mL/min. Rinse container (and  $\text{Na}_2\text{SO}_4$ , if present) with 2 ca 5 mL portions hexane, transfer rinsings to column, and rinse walls of chromatgc tube with addnl small portions of hexane. Elute tetrasul at ca 5 mL/min with 200 mL eluant I. Change receivers and elute endosulfan I and II, endosulfan sulfate, and tetradifon at ca 5 mL/min with 200 mL eluant II. Conc. each eluate to suitable definite vol. in Kuderna-Danish concentrator. For evapn to <5 mL, use 2-ball micro Snyder or micro Vigreux column.

#### 29.034

#### Determination

See 29.008(a)–(c).

Using the 10% DC-200 column, retention times relative to aldrin are ca 1.6 for endosulfan I, 2.2 for endosulfan II, 2.5 for tetrasul, 2.7 for endosulfan sulfate, and 5.4 for tetradifon.

### PCB in Paper and Paperboard (5)—Official First Action

#### 29.035

#### Apparatus

- (a) *Gas chromatograph*.—Equipped with electron capture detector and 1.85 m (6')  $\times$  4 mm id glass column contg either (1) 10% DC-200 or (2) 1+1 mixt. of 15% QF-1 + 10% DC-200 on

80–100 mesh Chromosorb W(HP). Operating conditions: temps ( $^{\circ}$ )—column and detector 200, injector 225; flow rate, 120 mL N/min; concentric design electron capture detector operated at dc voltage to cause  $\frac{1}{2}$  full scale recorder deflection for 1 ng heptachlor epoxide when full scale deflection is  $1 \times 10^{-9}$  amp (see 29.008(c)).

- (b) *Chromatographic tubes*.—See 29.005(b).

- (c) *Filter tube*.—See 29.005(d).

- (d) *Kuderna-Danish concentrator*.—See 29.005(e), and (g).

- (e) *West condenser*.—400 mm jacket length with  $\frac{1}{8}$  inner drip joint to fit 250 and 500 mL erlenmeyers.

#### 29.036

#### Reagents

- (a) *Florisil*.—See 29.002(i).  
 (b) *Alcoholic potassium hydroxide soln*.—2% KOH in alcohol or redistd MeOH.  
 (c) *Petroleum ether*.—See 29.002(m).  
 (d) *Polychlorinated biphenyls*.—Com. mixts (Aroclors) for ref. in GLC detn (Analabs, Inc.).

#### 29.037

#### Extraction

[Caution: See 51.039, and 51.073.]

Cut paper sample representative of lot into pieces ca  $6 \times 6$  mm and mix thoroly.

Weigh 10 g sample into 250 mL erlenmeyer. Do not pack tightly. (See note below if vol. of 10 g sample is >50 mL.) Add 60 mL 2% alc. KOH, and fit flask with West condenser cooled with circulating cold tap  $\text{H}_2\text{O}$ . Reflux gently on steam bath 30 min. Rinse inside of condenser with small amt of alcohol. Transfer soln thru glass wool plug in small funnel, to 250 mL separator, avoiding transfer of any paper material. Rinse paper and flask with three 40 mL portions pet ether, combining rinses in separator. Add 60 mL  $\text{H}_2\text{O}$  to separator and shake vigorously 30 sec. Drain lower aq. layer into second 250 mL separator. Add 60 mL pet ether to second separator and shake vigorously 30 sec. Discard aq. layer and combine pet ether layers in first separator. Rinse second separator with several small portions pet ether, collecting rinses in first separator. Wash pet ether with three 40 mL portions  $\text{H}_2\text{O}$ , discarding each wash. Dry pet ether thru 50 mm column, (c), of anhyd.  $\text{Na}_2\text{SO}_4$ , collecting eluate in Kuderna-Danish concentrator. Rinse separator and then column with 3 ca 20 mL portions pet ether, collecting rinses. Conc. combined pet ether ext and rinses on steam bath to ca 5 mL. Ext is ready for cleanup on Florisil column, 29.038. If experience with particular sample types indicates that Florisil column cleanup is not required, proceed to GLC detn, 29.018.

*Note:* Adequate extn of low density paper such as newspaper or tissue paper will require adjustment of either amt of sample to <10 g or vol. of reflux soln to >60 mL. Preferably, reduce sample to wt that is completely covered and wetted by 60 mL KOH soln. Increase in vol. of reflux soln >60 mL must be accompanied by proportional increases in vols of pet ether rinses of sample,  $\text{H}_2\text{O}$  diluent added to alc. reagent in separator, and size of erlenmeyers and separators.

#### 29.038

#### Florisil Cleanup

Proceed as in 29.015, pars 1 and 2, except prep. 10 g column, pre-wet column with 20 mL pet ether, and elute at ca 5 mL/min with 150 mL pet ether. Concd eluate is suitable for analysis by GLC with electron capture detection, 29.018.

*Note:* Waxes, if present in ext, can be removed before Florisil chromatgy by partitioning between pet ether and  $\text{CH}_3\text{CN}$ , 29.014.

## MULTIPLE RESIDUE METHODS FOR ORGANOPHOSPHORUS PESTICIDES

### Carbon Column Cleanup Method (6)—Official Final Action

(CH<sub>3</sub>CN extn and charcoal cleanup column using KCl thermionic or flame photometric detector for residues of parathion, paraoxon (diethyl *p*-nitrophenyl phosphate), carbophenothion and its O analog, and EPN (*O*-ethyl *O*-(*p*-nitrophenyl) phenylphosphonothioate) on apples and green beans)

#### 29.039

#### Reagents

(a) *Solvents*.—Redistd from glass (see 29.001): EtOAc, CH<sub>2</sub>Cl<sub>2</sub>, benzene, hexane, CH<sub>3</sub>CN, and isopropanol.

(b) *Acid-treated charcoal*.—Slurry 200 g Norit SG Extra (American Norit Co., Inc., 6301 Glidden Way, Jacksonville, FL 32208) or 100 g Nuchar C-190N (no longer marketed) with 500 mL HCl, cover with watch glass, and stir mag. while boiling 1 hr. Add 500 mL H<sub>2</sub>O, stir, and boil addnl 30 min. Collect charcoal in buchner and wash with H<sub>2</sub>O until washings are neut. to universal indicator paper. Dry at 130° in forced-draft oven.

(c) *Magnesium oxide*.—See 29.002(k).

(d) *Adsorbent mixture*.—Mix 1 part acid-treated charcoal, 2 parts hydrated MgO, and 4 parts Celite 545, acid washed. Keep sealed.

(e) *Pesticide std solns*.—Prep. solns contg 1 µg/mL EtOAc of each of following: parathion, paraoxon, carbophenothion, carbophenothion O analog, and EPN.

(f) *Eluting soln*.—CH<sub>3</sub>CN-benzene (1+1).

*Purity test*.—Reagents must be free of substances causing KCl thermionic detector response, as indicated by following test: Carry reagents thru entire method, and inject 5 µL from final conc. into gas chromatograph, using conditions described in 29.049. Conc. must not cause recorder deflection >1 mm from baseline for 2–60 min after injection.

#### 29.040

#### Apparatus

See also 29.005 and 29.045(a).

(a) *Vacuum adapter*.—Kontes Glass Co., No. K-954002, or equiv.

(b) *Gas chromatograph with potassium chloride thermionic detector*.—See 29.045(i) and (k).

(c) *Column*.—See 29.045(j).

(d) *Potassium chloride thermionic detector (KCITD)*.—See 29.008(d)(1) or (2), (e), (f), and (k). Also check linearity of GLC system to paraoxon and carbophenothion O analog.

(e) *Flame photometric detector (FPD)*.—With P selective optical filter for 526 nm wavelength (Tracor, Inc., 6500 Tracor Ln, Austin, TX 78721). Equiv. to KCITD for detn of organophosphorus pesticides in fruits and vegetables. (Note: Older commercial models of FPD may give rise to adsorption and/or degradation of O analogs of organophosphorus pesticides within detector's gas mixing chamber. Design changes of detectors manufactured after mid-1973 have generally corrected this problem. Flameout in FPD, on injection of sample, can be avoided by letting H enter detector (lower part) so that H and GLC column effluent mix before burner area. Air-O enters detector thru upper part. This arrangement reverses that recommended by manufacturer. Specifications for physical modification of FPD to correct above problems are available from Division of Chemistry and Physics, Food and Drug Administration, Washington, DC 20204.) Use highly stabilized 0–750 v dc variable power supply capable of 10 ma output (Model 240 A; Keithley Instruments, Inc., 28775 Aurora Rd, Cleveland, OH 44139, or equiv.), 6.3 v ac ignitor power supply, electrometer with bucking capability of  $1 \times 10^{-6}$  amp (Tracor, Inc., or equiv.), and variable transformer capable

of delivering 150 watts to control temp. of flame housing. Strip chart recorder should be compatible with electrometer.

(f) *Hydrogen*.—From cylinder of compressed H gas. Equip cylinder with regulator, delivery line, and variable flow controller capable of 200 mL/min delivery. Metering shut-off valve is required sep. from controller.

(g) *Air*.—Cylinder of compressed air equipped as in (f) to deliver up to 100 mL/min. Sep. shut-off valve is not needed.

(h) *Oxygen*.—Cylinder of compressed O gas equipped as in (f) to deliver up to 50 mL/min. Combine with air using std Swagelok tee before detector inlet.

(i) *Flame photometric detector operation*.—Adjust temp. of burner housing to ca 170–180° before igniting flame. Temp. will rise 20–30° after ignition. Do not allow detector to exceed 220°. Adjust gas flows at controllers to ca 150–300 mL/min H, 50–100 mL/min air, and 5–20 mL/min O. Adjust column effluent flow, 29.018(a), to 120 mL N/min. Turn off H flow with metering shut-off valve (f). (Caution: Before attempting ignition, make certain H has been purged from detector with other gases. One min interval between ignition attempts is adequate.) Apply ca 750 v to photomultiplier tube from power supply. Zero recorder with electrometer set at appropriate sensitivity (ca  $1 \times 10^{-8}$  to  $1 \times 10^{-9}$  amp full scale). Push ignitor button and then slowly open H metering shut-off valve. Recorder pen will not return to zero baseline if flame ignites. If ignition is not effected, shut off H valve, increase O flow, and repeat ignition procedure. Establish proper baseline with buckout control after flame is lit. Operate at sensitivity that produces ½ full scale recorder deflection for 2 ng parathion. Reduce photomultiplier voltage to reduce sensitivity. Alternatively, use electrometer sensitivity and attenuator controls to achieve proper response. Check linearity of GLC system to paraoxon and carbophenothion O analog.

#### 29.041

#### Preparation of Sample

Blend and filter sample as in 29.011(a), or (b). Transfer aliquot of CH<sub>3</sub>CN ext (30–35 mL) equiv. to ca 10 g sample from suction flask to 125 mL separator, add equal vol. CH<sub>2</sub>Cl<sub>2</sub>, shake vigorously 30 sec, and set aside 10–15 min to sep. Calc. g sample in aliquot as g sample  $\times$  [mL aliquot/(mL H<sub>2</sub>O in sample + mL extg solv. added – correction in mL for vol. contraction)].

#### 29.042

#### Charcoal Cleanup

Fit 1-hole No. 5 rubber stopper onto tip of chromatgc tube, 29.005(b), add side-arm vac. adapter and  $\frac{3}{4}$  24/40 receiving flask, open stopcock, and connect app. to open vac. line. Place 1 g Celite 545 in tube, tamp, add 6 g absorbent mixt., and tamp again. Add 2 cm glass wool plug on top of adsorbent. Prewash column with 100 mL eluting soln. Close stopcock when eluting soln is ca 2 cm above glass wool and maintain this head to ensure clean column. Disconnect vac., replace flask with 500 mL Kuderna-Danish flask equipped with 10 mL tube, 29.005(e) (check calibration at 1 mL), and reconnect to open vac. line.

Drain lower CH<sub>2</sub>Cl<sub>2</sub> layer in separator onto column, retaining H<sub>2</sub>O layer (upper phase) in separator. Open column stopcock to vac. and adjust flow to ca 5 mL/min. Re-ext H<sub>2</sub>O layer cautiously (do not shake vigorously) with two 10 mL portions CH<sub>2</sub>Cl<sub>2</sub> and add exts to column. Discard H<sub>2</sub>O phase. Elute column with 120 mL eluting soln (column may be taken to dryness). Disconnect app. and rinse column tip and vac. adapter with several mL EtOAc. Collect all rinses in same Kuderna-Danish concentrator with tube attached. Add 1 or 2 small boiling chips, attach Snyder column, and conc. cautiously over steam bath to ca 1 mL. (Caution: Begin heating very gently due to differences in densities and bps of individual solvs.) When cool, disconnect evaporative app. from Mills tube. Substitute column, 29.005(h),

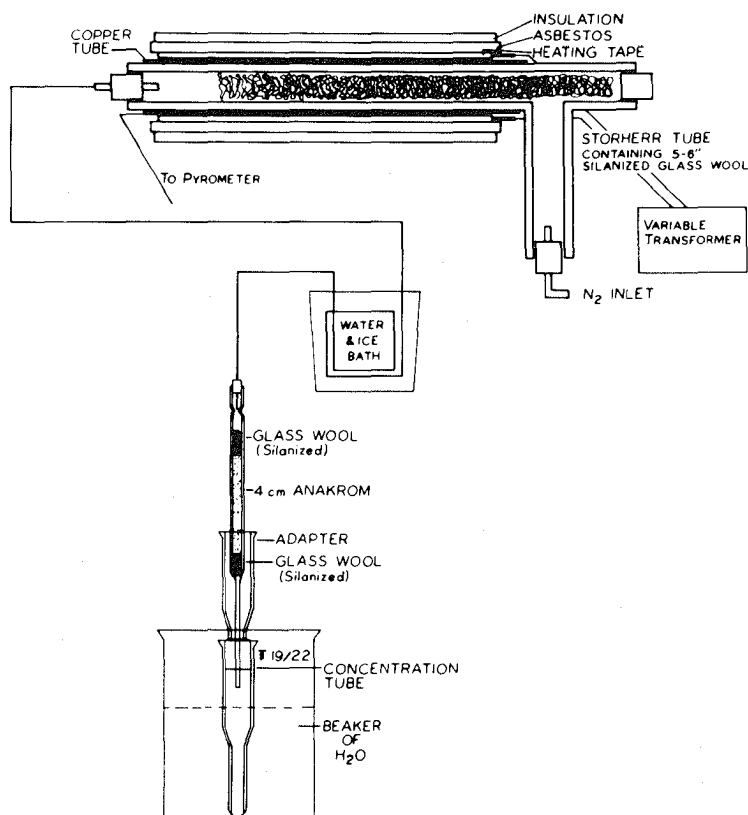

FIG. 29.06—Sweep co-distillation apparatus

on Mills tube, add boiling chips again, and conc. solv. to <1 mL. While app. is still immersed in steam bath, add 3–4 mL isopropanol (to remove  $\text{CH}_3\text{CN}$  azeotropically) and distil under gentle reflux. Repeat isopropanol addn and conc. to ca 0.5 mL. Remove from heat, cool, remove column, and adjust vol. to 1.0 mL with EtOAc.

**29.043****Gas-Liquid Chromatography**

Proceed as in 29.049, using recommended operating conditions / specified for column, 29.045(j)(1). (See 29.040(e)–(i) if using flame photometric detector.

**Sweep Codistillation Method (7)—Official Final Action**

(Sweep codistillation cleanup for parent organophosphorus residues of carbophenothion, *O,O*-diethyl-*O*-(2-isopropyl-6-methyl-4-pyrimidinyl) phosphorothioate (Diazinon®), ethion, malathion, Me parathion, and parathion in kale, endive, carrots, lettuce, apples, potatoes, and strawberries (fresh or non-sugared frozen); this cleanup is not adequate for electron capture gas chromatg detector. Use only with KCl thermionic detector.)

**29.044****Reagents**

(a) *Ethyl acetate*.—Redistd from glass. Check suitability of reagent by concg 100 mL to 2 mL. Inject 5  $\mu\text{L}$  into GLC (KCl thermionic detector) with operating conditions specified in 29.045(i). Chromatogram should show no peaks to 20 min with chart speed of 1"/2 min.

(b) *Pesticide std soln*.—Prep. EtOAc soln contg 1  $\mu\text{g}/\text{mL}$  of each of following: carbophenothion, Diazinon, ethion, malathion, Me parathion, and parathion.

**29.045****Materials and Apparatus**

(a) *Glass wool*.—Silane-treated (available from Applied Science Laboratories, Inc.).

(b) *Anakrom ABS*.—80–90 mesh. Remove fines by stirring with EtOAc, decanting several times, and drying.

(c) *Teflon tubing*.—AWG No. 16, std, natural.

(d) *Disposable glass capillary pipets*.—145 mm long, 6 mm id, with capillary stem (Arthur H. Thomas Co. No. 7760-B10, or equiv.).

(e) *Syringes*.—1 mL Tuberculin Luer-Lok and 2 mL Luer-Lok with Luer-Lok 2" No. 25G needles.

(f) *High-speed blender*.—400 mL capacity. Omnimixer (available from DuPont Instruments/Sorvall, Peck's Ln, Newtown, CT 06470), or equiv.

(g) *Sweep co-distillation apparatus*.—See Fig. 29.06. Following tubes are required: (1) *Storherr tube*.—24.5 cm long, 6 mm id (Kontes Glass Co., No. K-898600, or equiv.). (2) *Concentrating tube*.—10 mL calibrated to 0.5 mL. (3) *Adapter for extension of concentration tube*.—7 cm long, 19/22 (Kontes No. K-570100 (K-500750 part 355), or equiv.). Complete app. available from Kontes Glass Co. as No. K-500500.

(h) *Kuderna-Danish concentrators*.—500 mL with Snyder distilling column and 5 mL vol. and 10 mL graduated (Mills tube) receiving flasks, 19/22 (Kontes Glass Co., No. K-570000, K-621400, and K-570050, or equiv.).

(i) *Gas chromatograph with potassium chloride thermionic detector*.—See 29.008(a). Only thermionic detector, 29.008(d), is required.

Following conditions are important in operation of GLC and KCl thermionic detector:

(1) Every day before starting work change silane-treated glass

wool plug insert in injection port of GLC column. Remove and replace only that portion affected by syringe.

(2) Every week before starting work reheat KCl spiral over gas burner and reinsert into detector. Detector must then equilibrate ca 2 hr before use.

(j) *Column*.—10% DC 200 or OV-101 on 80–100 mesh Chromosorb W HP in glass column 1.85 m (6')  $\times$  4 mm id; see 29.008(b). Adjust column temp to give retention time for parathion of ca 5 min.

(1) *Recommended operating conditions: I*.—Temps ( $^{\circ}$ ): injection 225, column 200, detector 210; N flow 120 mL/min. Split column effluent with 1:1 stream splitter so that only 60 mL N/min enters KCITD. (2) *Recommended operating conditions II*.—Temps ( $^{\circ}$ ): column 220, injector and detector 240; N flow 60 mL/min.

(k) *Potassium chloride thermionic detector (KCITD)*.—See 29.008(d)(1) or (2), (e), (f), and (k).

## 29.046

### Preparation of Apparatus

App. is constructed in 3 parts: removable Storherr tube, permanent heating coil, and distillate collector (see Fig. 29.06). Com. model is available from Kontes Glass Co.

(a) *Preparation of removable Storherr tube*.—Pack Storherr tube with silane-treated glass wool. Use silane-treated glass wool as received. Do not pack glass wool too tightly; otherwise removal for cleaning is difficult. Only 13–15 cm portion from injection end requires packing. Insert injection septum and two 1-hole septums. Tube is now ready for use. Use clean tube for each sample. Clean tubes thoroly with soap and H<sub>2</sub>O after use, rinse with acetone, and dry. Soak tubes difficult to clean in chromic acid cleaning soln before cleaning with soap and H<sub>2</sub>O.

(b) *Preparation of permanent heating coil*.—Attach bimetallic wires of calibrated pyrometer directly to outside middle area of Cu tube (length 20 cm (8")  $\times$  11 mm (7/16") id). (Thermometer with stem covered with Al foil may also be used for temp. measurement.) Wrap heating tape (60  $\times$  1.3 cm) uniformly around outside of Cu tubing and over bimetallic wires or thermometer, and secure ends. Cover heating tape with asbestos tape and secure with glass tape or glass thread. Cover asbestos with several layers of Al foil and secure with tape.

Place heating assembly on ring stand, using asbestos-covered 3-prong clamp. Orient and use heating coil in near horizontal position. Attach heating tape leads to variable transformer. Adjust transformer so pyrometer reads 180–185 $^{\circ}$ . Use this setting or temp. for all crop cleanup.

Add N flow, 600 mL/min, to sidearm of Storherr tube. (For N pressure gage to give meaningful readings, add stainless steel capillary tube to reduce gas flow. Connect capillary tube directly to 1-hole septum in sidearm of tube with short length Teflon tubing.) Measure N flow with gas flow gage, and calibrate pressure regulator gage by this means.

(c) *Sample distillate collector*.—Construct in 3 parts: cooling coil, scrubber tube, and concn tube with extended adapter.

(1) *Cooling coil*.—Cut 120 cm length of Teflon tubing. Form this tubing into three 7 cm diam. loops having 2 arms of ca 20 cm lengths. Attach Teflon cooling coil and 1-hole septum directly to Storherr tube. Place coils in 250 mL beaker contg ice and H<sub>2</sub>O. Place 250 mL beaker inside 400 mL beaker for insulation.

(2) *Scrubber tube*.—Insert silane-treated glass wool plug in constricted end of disposable pipet. On outside of pipet place marks 4 and 6 cm above top of glass wool plug. Add Anakrom ABS to 6 cm mark and pack Anakrom to 4 cm mark by compressing with 3 mm rod. Place silane-treated glass wool plug on top of packed Anakrom and 1-hole septum in pipet top. Connect exit arm of Teflon cooling coil directly into 1-hole septum in scrubber tube and extending ca 2 cm below septum.

Secure scrubber tube on sep. ring stand with 3-prong clamp. Scrubber tube must be lower than cooling bath, especially in rinsing step.

(3) *Concentration tubes*.—Use 10 mL calibrated tubes, 29.045(h). Adapter, (g)(3), is needed for insertion into concn tube to prevent splash during sweep and rinsing steps. Place tip of scrubber thru adapter and into concn tube. If possible, place scrubber tip against wall of concn tube. Hold tube in place with clamp.

Adjust heat to 180–185 $^{\circ}$  and N flow to 600 mL/min (measure before entering Storherr tube). Flush several 0.5 mL EtOAc injections thru entire system, using 2 mL syringe (used for all rinsings). Replace concn tube with clean tube and insert adapter; assembly is ready for use.

## 29.047

### Extraction

Ext all crops with EtOAc in exact order as follows: To high-speed blender, add 25 g chopped sample, 125 mL EtOAc from pipet, and 25 g anhyd. granular Na<sub>2</sub>SO<sub>4</sub>. Blend 5 min at slow speed; then 5 min at high speed with mixer cup immersed in ice-H<sub>2</sub>O bath. Decant liq. thru 2.5 cm silane-treated glass wool plug contained in short glass chromatgc tube. (Do not add solids to glass wool plug.) Collect EtOAc ext (ca 100 mL) in 125 mL flask or bottle. Remove 50 mL aliquot (equiv. to 10 g original sample) and place in Kuderna-Danish concentrator with Snyder column, calibrated Mills tube, or 5 mL vol. receiving flask, and conc. to ca 5 mL. Adjust vol. to exactly 5.0 mL, using air jet or adding EtOAc. Use 1 mL aliquots (2 g sample) for sweep co-distn cleanup.

Store all stds and crop solns at  $\leq 0^{\circ}$  when not in use. Warm to room temp. ca 1 hr before use.

## 29.048

### Sweep Co-Distillation Cleanup

Assemble app. as in Fig. 29.06, except position Storherr tube and heating unit so exit end of Storherr tube is ca 10 $^{\circ}$  below horizontal to avoid backup of sample into N inlet arm. If sample backs up, discard detn. Check temp. (180–185 $^{\circ}$ ), N flow (600 mL/min), and receiver tube. Inject 1 mL (2 g) sample, using 1 mL Luer-Lok tuberculin syringe. Immediately follow sample with injection of 0.5 mL EtOAc sweeping solv. and repeat 0.5 mL EtOAc injection every 3 min for 21 min. After last injection wait 1 min until solv. has cleared cooling coil and scrubber tube; then disconnect cooling coil arm with septum from Storherr tube. Disconnect septum with attached cooling coil arm from scrubber tube and rinse 2 cm Teflon projection, collecting rinse in scrubber tube (still in position in concn tube). With septums in place on disconnected cooling coil arms, reverse coil arms and place that end formerly in Storherr tube into scrubber tube. Make certain that Teflon tubing in this arm extends 2 cm into scrubber tube below inserted septum (similar to position when cleaning up sample). Slowly inject 1 mL EtOAc rinse from 2 mL syringe directly into open end of cooling coil arm formerly in scrubber tube. Gently force rinse, using N flow from disconnected Storherr tube, thru cooling coil into scrubber tube and into concn tube. Repeat 1 mL EtOAc rinse 1–2 addnl times. Rinse scrubber tip end and inside of adapter, remove scrubber, disconnect adapter, and rinse  $\frac{3}{4}$  joint. Collect all rinses in concn tube. Rinse down sides of concn tube and conc. to 1 mL, using N or air jet. Prevent H<sub>2</sub>O condensation inside tubes by placing tube in room temp. H<sub>2</sub>O bath during this step. If cleaned up soln is too concd for GLC detn ( $>2 \mu\text{g/mL}$ ), dil. soln to 5 or 10 mL with EtOAc. If calibrations of Mills tube are incorrect (most usually are except for 1 mL mark), quant. transfer the concd soln to 5 or 10 mL vol. flask, using disposable pipet with attached rubber bulb. Rinse inside of tube with EtOAc and transfer rinse

in same pipet. Repeat this rinse of tube and pipet several times; then rinse inside of pipet into flask, using EtOAc. Dil. to vol. Further diln with EtOAc or concn may be necessary to bring concn within measurement range.

Anakrom scrubber tube is used repeatedly without change. Final EtOAc rinses after each run keep it clean. However, if Anakrom becomes discolored, prep. new tube.

#### 29.049 *Determination by Gas-Liquid Chromatography*

Operate chromatograph under conditions specified for column, **29.045(j)**. Inject 3–8  $\mu$ L aliquot concd, cleaned-up soln contg amt of pesticide within linear range of gas chromatgc system, (i), using 10  $\mu$ L syringe. Tentatively identify residue peaks on basis of retention times. Det. amt of pesticide by comparing area under peak with that from known amt of appropriate std pesticide. For accurate detn, baseline current of sample and std must be identical during chromatgy.

Injections <3  $\mu$ L are difficult to reproduce; injections >8  $\mu$ L may cause flame blow-out. Sample wt is not critical—use injections equiv. to <1 mg or several hundred mg. Inject appropriate std immediately after every sample. Peak ht also may be used for detn, but only if ht of ref. std is ca same ht as sample unknown (width of base should then be same).

#### Single Sweep Oscillographic Polarographic Confirmatory Method (8)—Official Final Action

(Applicable to Diazinon, malathion, Me parathion, and parathion)

#### 29.050

#### Apparatus

(Wash all glassware with hot  $\text{HNO}_3$  (1+1) and rinse with  $\text{H}_2\text{O}$ .)

(a) *Polarograph*.—Any voltammetric or polarographic instrument capable of linear sweep voltammetry at 10 ng pesticide/mL cell soln (equiv. to 0.01 ppm based on 1 g sample in 1 mL cell soln).

(b) *Silver wire electrode*.—Deposit very thin coating of AgCl on No. 20 or 22 gage Ag wire as follows: Dip wire in 10%  $\text{HNO}_3$ , rinse in  $\text{H}_2\text{O}$ , and then let stand 10 min in 1N HCl.

#### 29.051

#### Reagents

(See statement regarding solvs, **29.001**.)

(a) *Acetonitrile*.—Distd in glass at  $82 \pm 1^\circ$ .

(b) *Acetone*.—Distil at  $56.5^\circ$  with 0.25 g  $\text{KMnO}_4/\text{L}$ . Distn must be performed as directed.

(c) *Ethyl acetate*.—Distd in glass at  $77 \pm 1^\circ$ .

(d) *Petroleum ether*.—Distd in glass at  $30\text{--}60^\circ$ .

(e) *Nitrogen*.—Prepurified,  $\text{H}_2\text{O}$ -pumped.

(f) *Tetramethyl ammonium bromide*.—Eastman No. 670, or equiv.

(g) *Electrolyte solns*.—(1) *For Diazinon*.—Dissolve 7.7 g  $\text{Me}_4\text{NBr}$  in 300 mL  $\text{H}_2\text{O}$ . Add 115 mL HOAc and dil. to 500 mL with  $\text{H}_2\text{O}$ . (2) *For malathion*.—Dissolve 15.4 g  $\text{Me}_4\text{NBr}$  in 300 mL  $\text{H}_2\text{O}$ . Add 0.2 g LiCl and 4.1 mL HCl, and dil. to 500 mL with  $\text{H}_2\text{O}$ . (3) *For methyl parathion and parathion*.—Dissolve 2.2 g NaOAc  $\cdot 3\text{H}_2\text{O}$  and 1.17 g NaCl in 100 mL  $\text{H}_2\text{O}$  and adjust to pH 4.8 with HOAc, using pH meter.

(h) *Pesticide std solns*.—(1) *Stock solns*.—Prep. individual solns contg 1.00 mg pesticide/mL EtOAc. Store at  $0^\circ$ . (2) *Intermediate solns*.—0.2 mg/mL. Transfer 5 mL stock soln to 25 mL vol. flask and dil. to vol. with pet ether for Diazinon, MeOH for malathion, and acetone for Me parathion and parathion.

#### 29.052

#### Preparation of Standard Curves

(a) *Diazinon*.—Transfer 0.0, 1.0, 2.0, 3.0, 4.0, and 5.0 mL intermediate std soln of Diazinon to individual 100 mL vol. flasks and dil. to vol. with pet ether. Transfer 1.0 mL of each soln to sep. 50 mL erlenmeyers and evap. to incipient dryness under gentle jet of dry air. Evap. remaining solv. with warmth of hand. Dissolve residue in 5.0 mL electrolyte soln, (g)(1). Transfer soln to polarographic cell, adjust to  $25 \pm 1^\circ$ , and bubble N thru soln 5 min. Polarograph between  $-0.70$  and  $-1.2$  v against either Hg pool or Ag wire ref. electrode.

Peak potential for Diazinon at  $25^\circ$  is  $-0.90 \pm 0.05$  v against either electrode. Plot  $\mu\text{g}$  diazinon/mL cell soln against peak ht in units  $\times$  instrument sensitivity setting.

(b) *Malathion*.—Transfer 0.0, 1.0, 2.0, 3.0, 4.0, and 5.0 mL intermediate std soln of malathion to individual 25 mL vol. flasks and dil. to vol. with MeOH. Transfer 2.0 mL of each soln to sep. 50 mL erlenmeyers and add 1.0 mL 0.1N KOH. After 3 min, add 2.0 mL electrolyte soln, (g)(2), mix well, and let stand 5 min. Transfer to polarographic cell, adjust to  $25 \pm 1^\circ$ , and bubble N thru soln 5 min. Polarograph between  $-0.5$  and  $-1.0$  v against either Hg pool or Ag wire electrode.

Peak potential for malathion at  $25^\circ$  is  $-0.82 \pm 0.05$  v against Ag wire and  $-0.85 \pm 0.05$  v against Hg pool ref. electrodes. Plot  $\mu\text{g}$  malathion/mL cell soln against peak ht in units  $\times$  instrument sensitivity setting. (Note: Compd actually polarographed is fumaric acid resulting from basic hydrolysis of malathion.)

(c) *Parathion and methyl parathion*.—Transfer 0.0, 1.0, 2.0, 3.0, 4.0, and 5.0 mL intermediate parathion (or Me parathion) std soln to individual 100 mL vol. flasks and dil. to vol. with acetone. Transfer 5.0 mL aliquots of each soln to sep. 50 mL erlenmeyers, add 5.0 mL electrolyte soln, (g)(3), mix well, and transfer ca 5 mL to polarographic cell. Adjust to  $25 \pm 1^\circ$ , bubble N thru soln 5 min, and polarograph between  $-0.4$  and  $-0.9$  v against either Hg pool or Ag wire ref. electrode.

Peak potential for parathion and Me parathion at  $25^\circ$  is  $-0.68 \pm 0.05$  v against Hg pool and  $-0.70 \pm 0.05$  v against Ag wire ref. electrodes. Plot  $\mu\text{g}$  pesticide/mL cell soln (10 mL) against peak ht in units  $\times$  instrument sensitivity setting. Cell soln vol. = 5 mL sample soln + 5 mL electrolyte soln.

#### 29.053

#### Preparation of Sample Solution

Prep., ext, and clean up samples as in **29.011–29.015**. Conc. 15% and 50% eluates from Florisil column to suitable definite vol. in Kuderna-Danish concentrator. All eluting solvs must be peroxide-free by test in *Definitions and Explanatory Terms*, item (3).

#### 29.054

#### Determination

(a) *Parathion and/or methyl parathion*.—Transfer aliquot of concd 15% Florisil eluate, equiv. to 5 g crop, to 50 mL erlenmeyer. Carefully evap. to dryness under gentle jet of air at room temp. Dissolve residue in 3.0 mL acetone. (Note: Since good polarograms can be obtained by using as little as 0.5 mL soln in cell, min. of 0.25 mL acetone can be used to dissolve residue.) Add 3.0 mL electrolyte soln, (g)(3), mix well, transfer to polarographic cell, and adjust to  $25 \pm 1^\circ$ . Bubble N thru soln 5 min and polarograph as in **29.052(c)**. Measure ht of wave whose peak potential corresponds to that of parathion, and det. concn from freshly prepd std curve or by comparing wave hts of sample soln with those of std soln polarographed immediately before or after sample. (Latter method is recommended for greater accuracy.)

Calc.  $\mu\text{g}/\text{mL}$  as follows:

$$C_{\text{sample}} = [(WH_{\text{sample}}) \times (IS_{\text{sample}} \times C_{\text{std}})] / [(WH_{\text{std}}) \times (IS_{\text{std}})]$$

where  $C = \mu\text{g pesticide/mL cell soln}$ ;  $WH = \text{wave ht}$ ;  $IS = \text{instrument sensitivity setting}$ .

$\text{ppm} = (C_{\text{sample}} \times \text{mL sample soln})/\text{g sample}$ .

Limit of quant. detn is 0.01 ppm based on 1 g crop in 1 mL cell soln.

Me parathion, parathion, and paraoxon polarograph at ca same peak potential. If any one of these pesticides is present as indicated by multiple residue methods, it should be polarographed against that std. If these pesticides are present together, use mixed std contg ratio of pesticides as estd from analysis by multiple residue method. (Paraoxon will not be recovered by cleanup specified.)

Other pesticides known to give polarographic peak potentials similar to parathion are pentachloronitrobenzene (PCNB), 1,2,4,5-tetrachloro-3-nitrobenzene (TCNB, tecnazene), and *O*-ethyl *O*-*p*-nitrophenyl phenylphosphonothioate (EPN). PCNB and TCNB are recovered in 6% Florisil eluate and will not interfere. Verify presence or absence of EPN by GLC or TLC.

(b) *Diazinon*.—Transfer aliquot of concd 15% Florisil eluate, equiv. to 5 g crop, to 50 mL erlenmeyer. Carefully evap. just to dryness, using gentle jet of dry air at room temp. Dissolve residue in 5.0 mL electrolyte soln, (g)(1). Transfer soln to polarographic cell and adjust to  $25 \pm 1^\circ$ . Bubble N thru soln 5 min and polarograph as in 29.052(a). Calc. amt of Diazinon present as in (a).

Limit of quant. detn is 0.2 ppm based on 1 g crop sample in 1 mL cell soln.

(c) *Malathion*.—Transfer aliquot of concd eluate from 50% Florisil eluate, equiv. to 5 g crop, to 50 mL erlenmeyer. Carefully evap. just to dryness under gentle jet of dry air at room temp. Dissolve residue in 2.0 mL MeOH, add 1.0 mL 0.1*N* KOH, and let stand 3 min. Add 2.0 mL electrolyte soln, (g)(2), mix well, and let stand 5 min. Transfer to polarographic cell, adjust to  $25 \pm 1^\circ$ , bubble N thru soln 5 min, and polarograph as in 29.052(b). Calc. amt of malathion present as in (a).

Limit of quant. detn is 0.3 ppm based on 1 g crop in 1.0 mL cell soln.

*Note 1:* If polarogram cannot be obtained because of high residual currents, check concd eluate for peroxides. If peroxides are present, transfer 5 mL concd eluate to small separator contg 25 mL 3%  $\text{FeSO}_4$  soln; shake well and discard aq. layer. Transfer 1.0 mL ether layer to 50 mL erlenmeyer and proceed as in (a), (b), or (c).

*Note 2:* All glassware used for polarographic detns should be thoroly washed with hot  $\text{HNO}_3$  (1+1) and rinsed with distd  $\text{H}_2\text{O}$ .

#### 29.055 ★ Cholinesterase Inhibition Method (9) ★ Official First Action

Nonspecific measure of  $\text{H}_2\text{O}$ -sol., cholinesterase inhibiting substances; applicable to alpha isomer of 2-carbomethoxy-1-methylvinyl dimethyl phosphate (Phosdrin®) in fruits and vegetables. See 29.049–29.055, 12th ed.

#### MULTIPLE RESIDUE METHODS FOR FUMIGANTS

##### Volatile Fumigants in Grain (10)—Official First Action

(Applicable to  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{Cl}_2\text{CCClH}$ , and  $\text{BrH}_2\text{CCH}_2\text{Br}$  in wheat and corn grain)

#### 29.056

##### Apparatus and Reagents

(a) *Column*.—4 m  $\times$  2.2 (id) mm stainless steel packed with 15% polypropylene glycol (LB 550X, Ucon fluid) on 60–80 mesh Chromosorb W.

(b) *Gas chromatograph*.—Isothermal with source-heated electron capture detector and glass-lined heated injection block. (100–200 mCi  $^3\text{H}$  with Ar as  $\beta$ -ionization detector is more useful

for multiresidue detns than  $^{63}\text{Ni}$  and N.) Use 1 mv recorder with max. response time of 1 sec and chart speed of 0.5 cm/min. Operate electron capture detector with N at 25 psi (173 kPa) at  $95^\circ$  with polypropylene glycol column for  $\text{CCl}_4$  (retention time, ca 6 min). Use  $120^\circ$  for  $\text{CHCl}_3$  (3 min),  $\text{Cl}_2\text{CCClH}$  (4 min), and  $\text{BrH}_2\text{CCH}_2\text{Br}$  (8 min).

(c) *Acetone*.—Check for interfering peaks by gas chromatogry before use.

#### 29.057

##### Determination

(Caution: see 51.046.)

Store sample at  $\leq 5^\circ$ . Quickly weigh 50 g and immerse in 150 mL acetone- $\text{H}_2\text{O}$  (5+1) in 250 mL g-s flask, and stopper. Let stand 48 hr in dark at  $20\text{--}25^\circ$ , swirling at 24 hr. Decant 10 mL supernate into 25 mL g-s graduate, add 2 g NaCl, stopper, and shake vigorously 2 min. Let stand until layers sep. Pour 5 mL clear upper layer into 10 mL g-s graduate, add 1 g anhyd.  $\text{CaCl}_2$ , stopper, and shake 2 min. Let stand 30 min with occasional shaking.

Withdraw 0.5  $\mu\text{L}$  aliquots from upper layer into 1  $\mu\text{L}$  syringe. Inject into gas chromatograph. Dil.  $10\times$  or  $100\times$  with dry acetone, if necessary to avoid overloading detector. Inject all solns in triplicate and average results.

Construct calibration curve daily of peak hts against ng fumigant/125 mL acetone for suitable range.

#### MULTIPLE RESIDUE METHOD FOR ARYL N-METHYLCARBAMATE INSECTICIDES

Carbanolate (6-Chloro-3,4-xylyl methylcarbamate), Carbaryl (1-Naphthyl methylcarbamate), Carbofuran (2,3-Dihydro-2,2-dimethyl-7-benzofuranyl methylcarbamate), and Propoxur (*o*-Isopropoxyphenyl methylcarbamate)

##### Gas Chromatographic Method (11)—Official Final Action

(Applicable to apples, cabbage, collards, corn kernels, green beans, kale, and turnip tops. Rinse all glassware with acetone and then distd  $\text{H}_2\text{O}$  before use.)

#### 29.058

##### Principle

Residue is extd from crop with  $\text{CH}_3\text{CN}$ , and ext is purified by partitioning with pet ether and coagulating with  $\text{H}_3\text{PO}_4\text{--NH}_4\text{Cl}$  soln. Phenolic impurities are largely eliminated by partitioning  $\text{CH}_2\text{Cl}_2$  ext with KOH soln. Carbamate residues are treated with 1-fluoro-2,4-dinitrobenzene to form ether derivative. Residues may be detd at levels  $\geq 0.05$  ppm. Recoveries range from 90 to 110%.

#### 29.059

##### Reagents

(a) *Borax*.—5% aq. soln.

(b) *Diatomaceous earth*.—Wash thoroly with acetone and dry 2 hr at  $110^\circ$ .

(c) *Coagulating soln*.—(1) *Stock soln*.—Dissolve 20 g  $\text{NH}_4\text{Cl}$  and 40 mL  $\text{H}_3\text{PO}_4$  in 360 mL  $\text{H}_2\text{O}$ . (2) *Working soln*.—Dil. 100 mL stock soln to 1 L for coagulation.

(d) *1-Fluoro-2,4-dinitrobenzene soln*.—(Eastman Kodak Co.) Redistil at  $128^\circ$  and 1 mm pressure. Dissolve 1.5 mL in 25 mL acetone.

(e) *Pesticides*.—Best quality obtainable from manufacturer; anal. grades when available.

(f) *Potassium hydroxide soln*.—0.5*N* aq. soln.

(g) *Sodium chloride soln*.—30% aq. soln.

(h) *Solvents*.—Acetone,  $\text{CH}_2\text{Cl}_2$ , isooctane,  $\text{CH}_3\text{CN}$ , and pet ether (distd in glass; see statement regarding solvs, 29.001); acetophenone and MeOH (anal. grade).

★ Surplus method—see inside front cover.

## 29.060

**Gas Chromatographic Apparatus**

Gas chromatograph equipped with  $^3\text{H}$  electron capture detector and  $46 \times 0.64$  (od) cm ( $18 \times \frac{1}{4}$ ") glass column contg 10% DC-200 (12,500 cst) on 60–70 mesh Anakrom ABS (Analabs, Inc.). Porous Teflon end plugs for  $\frac{1}{4}$ " od glass tubing (Chemical Research Services, Inc., 852 Westgate Dr, Addison, IL 60101) are preferable, but glass wool can be used at outlet and omitted at inlet if necessary. (Glass wool at inlet tends to adsorb derivatives gradually and to release them later, giving rise to "ghost images" of compds.)

Equilibrate column 2 days at  $250^\circ$  and 2 weeks at  $212^\circ$ . Operating conditions: temps ( $^\circ$ )—column 212, detector 218, standby temps 190 and 200, resp.; N carrier gas 60 mL/min; sensitivity  $1 \times 10^{-9}$  amp full scale; and detector potential either 25 or 50 V, depending on response level needed ( $\frac{1}{3}$  to  $\frac{2}{3}$  full scale peak ht with injections of 4 ng carbamate).

Alternatively, use instrument with  $^{63}\text{Ni}$  detector and 1.8 m ( $6'$ )  $\times$  4 mm id glass column contg 10% DC-200 on 60–70 mesh Anakrom ABS. Do not use glass wool at beginning of column. Operating conditions: temps ( $^\circ$ )—column 232, detector 250, N carrier gas 80 mL/min, sensitivity  $1 \times 10^{-9}$  amp full scale, and detector potential 50 or 75 V.

## 29.061

**Extraction of Pesticides**

(Caution: See 51.004, 51.043, and 51.073)

Place 100 g sample and 200 mL  $\text{CH}_3\text{CN}$  (add 50 mL  $\text{H}_2\text{O}$  with fruit or other samples contg 5–15% sugar) in sq screw-top jar, and macerate in blender operated 2 min at moderate speed. Filter with suction into 500 mL r-b flask thru rapid paper in 11 cm buchner. Transfer aliquot equiv. to 40 g crop (mL aliquot = (mL  $\text{H}_2\text{O}$  in sample + mL  $\text{CH}_3\text{CN}$  added + mL  $\text{H}_2\text{O}$  added – 5 mL vol. contraction)  $\times$  40/100) to 250 mL separator. Shake 10 sec with 25 mL NaCl soln. Drain and discard aq. phase. Repeat with fresh NaCl soln. Add 100 mL pet ether, and shake 30 sec. Drain  $\text{CH}_3\text{CN}$  into 1 L separator. Strip pet ether by shaking 20 sec with 50 and 10 mL portions  $\text{CH}_3\text{CN}$ , draining each into the 1 L separator. Add 300 mL  $\text{H}_2\text{O}$ , 25 mL NaCl soln, and 50 mL MeOH. Ext mixt. with 100 mL and two 25 mL portions  $\text{CH}_2\text{Cl}_2$ , shaking each 20 sec, and drain lower layer into 500 mL r-b flask. Add 2 drops acetophenone, and evap. in rotary evaporator connected to aspirator pump. During evapn, keep  $\text{H}_2\text{O}$  bath within  $40$ – $50^\circ$  range and remove flask from  $\text{H}_2\text{O}$  bath when ext vol. has been reduced to few mL, so that final evapn to dryness takes place at low temp.

Add 5 mL acetone, and swirl flask to dissolve residue. Add 50 mL coagulating soln, swirl to mix, add 1–2 g diat. earth, and swirl again to mix. Pour soln into 150 mL suction filter of medium porosity packed with 6 mm ( $\frac{1}{4}$ ") diat. earth, and collect filtrate in 500 mL r-b flask. Break vac. immediately after liq. is drawn into diat. earth layer. Rinse sides of flask with 5 mL acetone, swirl, and repeat coagulation. Rinse flask with 20 mL coagulating soln, and add rinse to filter just after liq. of second coagulation is drawn into diat. earth layer. After filtration is complete (ca 5 min), transfer filtrate to 250 mL separator. Ext carbamates by shaking 20 sec with three 25 mL portions  $\text{CH}_2\text{Cl}_2$ , rinsing filter flask with each portion before adding to separator. Drain  $\text{CH}_2\text{Cl}_2$  (lower) ext into another 250 mL separator. Soln may be held overnight at this point. Add 40 mL  $\text{H}_2\text{O}$  and 10 mL 0.5N KOH, mix briefly by gentle swirling, and shake 20 sec. Drain  $\text{CH}_2\text{Cl}_2$  thru granular anhyd.  $\text{Na}_2\text{SO}_4$  supported by glass wool in filter funnel, and collect filtrate in 250 mL erlenmeyer. Add 10 mL  $\text{CH}_2\text{Cl}_2$  to separator, swirl gently, and drain org. phase. Repeat once. Rinse filter with two 10 mL portions  $\text{CH}_2\text{Cl}_2$ . Add 2 drops acetophenone, and evap. with same technic used in first evapn.

## 29.062

**Determination**

Add 100 mL  $\text{H}_2\text{O}$ , 2 mL 0.5N KOH, and 1 mL 1-fluoro-2,4-dinitrobenzene soln. Stopper, and mix 20 min at high speed on mech. agitator. Add 10 mL 5% borax, swirl to mix, and heat on steam bath 20 min. Cool to room temp. by placing flasks in shallow  $\text{H}_2\text{O}$  bath 10 min. Add 5 mL isooctane, stopper, shake 3 min at high speed, and pour into 250 mL separator. Drain aq. phase, and rinse twice with  $\text{H}_2\text{O}$ . Drain isooctane soln thru funnel contg 6 mm glass wool plug into g-s test tube. Soln may be held overnight at this point. Inject 10  $\mu\text{L}$  sample into gas chromatograph. If necessary to dil. sample, transfer 1 mL of isooctane ext to another test tube, dil. to exact vol. with isooctane, and shake to mix. Chromatograph std and sample solns at approx. same level of response.

Methylcarbamates, ppm = concn std  $\times$  (peak ht sample/peak ht std)  $\times$  ( $\mu\text{L}$  std/ $\mu\text{L}$  sample)  $\times$  (diln vol./aliquot vol.)  $\times$  5/40.

## 29.063

**Preparation of Standard Curves**

Dissolve 50 mg each carbamate in 100 mL benzene and store in brown bottles. Dil. 5 mL aliquots from these solns to 50 mL with benzene, and store in brown bottles. Transfer 50  $\mu\text{L}$  to 250 mL erlenmeyer, and derivatize as in 29.062. After extn of derivatives, solns will contain equiv. of 0.5 ng each carbamate/ $\mu\text{L}$ . Chromatograph 4, 6, 8, and 10  $\mu\text{L}$  and plot mm response against ng carbamate. If response is nonlinear, adjust GLC parameters and/or prep. more dil. ref. soln, e.g., equiv. of 0.25  $\mu\text{g}$  carbamate/mL, and establish suitable linear working range.

**METHODS FOR INDIVIDUAL RESIDUES****Benzene Hexachloride (Hexachlorocyclohexane, BHC)—Official Final Action****29.064 Multiple Residue Method**

See 29.001–29.028.

**29.065 ★ Colorimetric Method (12) ★**

BHC is removed from sample by extg with  $\text{CCl}_4$ . After removal of solv., BHC is dechlorinated to benzene by action of Zn and HOAc in presence of malonic acid, which slowly liberates  $\text{CO}_2$ , sweeping benzene formed into nitrating mixt. Benzene is converted in const but not quant. (ca 85%) proportion to *m*-dinitrobenzene. After extn, *m*-dinitrobenzene is treated with butanone-2 and alkali, and A of magenta colored compd formed is measured at 565 nm.

See 24.101–24.105, 10th ed. (Caution: See 51.011, 51.039, and 51.054.)

**29.066 ★ Distinction Between Lindane and Technical ★ BHC (13)—Official First Action**

BHC is extd with *n*-hexane. Ext is refluxed over fuming  $\text{H}_2\text{SO}_4$  and BHC is extd with  $\text{CH}_3\text{CN}$ . Purified ext is chromatgd on paper to sep. and identify isomers. (Caution: See 51.004, 51.011, 51.016, 51.030, 51.031, 51.039, and 51.061.)

See 24.107–24.110, 10th ed.

**Biphenyl (14)—Official Final Action**

(Applicable to citrus fruit)

## 29.067

**Principle**

Biphenyl is extd from blended peel or pulp by steam-liq.-liq. extrn. Ext is subjected to TLC and biphenyl zone is completely

★ Surplus method—see inside front cover.

scraped from developed plate. Biphenyl is eluted from adsorbent with alcohol for spectrophotric detn.

**29.068****Reagents**

- (a) *Silica gel*.—GF-254 (Brinkmann Instruments, Inc. No. 7730).  
 (b) *Biphenyl std solns.*—(1) *Stock soln.*—Approx. 0.5 mg/mL. Dissolve ca 50 mg accurately weighed biphenyl in *n*-heptane and dil. to 100 mL with *n*-heptane. (2) *Limit soln.*—Approx. 0.01 mg/mL. Dil. 5 mL stock std to 250 mL with *n*-heptane.

Use stock std soln for spectrophotric quantitation after TLC step. Limit std soln aids in locating biphenyl zone and in estg small amts.

**29.069****Apparatus**

- (a) *Thin layer apparatus*.—See 19.041; use 8 × 8" glass plates.  
 (b) *Spotting pipet*.—100  $\mu$ L (Kontes Glass Co. No. K-763800, or equiv.).  
 (c) *Tank liner*.—Whatman 3MM paper cut to fit tank.  
 (d) *Moisture test apparatus*.—Similar to lighter-than-H<sub>2</sub>O volatile oil trap, 30.020(a), Fig. 30.01, with cold finger condenser (SGA Scientific, Inc. No. JM-8590, or equiv.).

**29.070****Preparation of TLC Plates**

Mix 40 g silica gel with 80 mL H<sub>2</sub>O, shaking vigorously few sec, and finally swirling ca 30 sec to eliminate air bubbles. Spread slurry 0.3 mm thick over 5 plates. Let plates air dry in place ca 1 hr. Put plates in drying rack and place in 100° oven 2 min. Remove plates and store in desiccator over silica gel or CaCl<sub>2</sub> until used. Plates may be stored up to 30 days.

**29.071****Preparation of Sample**

Sort out and discard rotten units. Completely peel  $\geq 6$  whole fruits (include all white material under peel in peel portion). Weigh peelings and peeled fruit, and calc. wt ratio of peelings to peeled fruit.

- (a) *Peel*.—Grind combined peel in food grinder. Blend 200 g ground peel with 400 g H<sub>2</sub>O at high speed 5 min (or in five 1 min increments if blender becomes very warm), using high-speed blender. (Larger batches may be blended with large blender as long as peel-H<sub>2</sub>O ratio is same.)

- (b) *Peeled fruit*.—Cut peeled fruit into small pieces and blend at high speed 5 min (or in five 1 min increments if blender becomes very warm).

**29.072****Extraction**

Accurately weigh ca 300 g recently blended peel slurry or ca 100 g recently blended peeled fruit, and transfer to 1 L r-b 29/42 flask with enough H<sub>2</sub>O to yield total vol. of ca 500 mL; add few boiling chips (6 mesh granular SiC is convenient). Connect extn unit of moisture test app. to flask and fill side arm with H<sub>2</sub>O to overflowing. Place ca 3 mL *n*-heptane on top of H<sub>2</sub>O layer and insert cold finger cooled with very rapid flow of cold H<sub>2</sub>O. Gradually heat flask with mantle (controlled by variable transformer) until even boiling is obtained, then intensely enough to maintain vigorous boiling. Continue extn 3 hr from time mixt. starts boiling. (Wrap exposed portion of flask and connector arm between flask and extn unit with Al foil.) Initial carry-over of froth does not interfere. After 3 hr, discontinue heat and drain entire contents of extractor into 125 mL separator.

Discard lower layer and drain heptane extn thru 2.5 cm column of granular anhyd. Na<sub>2</sub>SO<sub>4</sub> (8–10 mm id column) into 10 mL vol. flask. Rinse separator with 1 mL *n*-heptane and add rinse to column. Rinse cold finger and extn unit with five 2 mL portions alcohol, collecting successive rinses in separator. Add 5 mL *n*-heptane to separator and shake vigorously few sec; add 50–75 mL H<sub>2</sub>O and shake moderately few sec. Let layers sep. (lower layer may remain slightly cloudy) and discard lower layer. Pass heptane layer thru same Na<sub>2</sub>SO<sub>4</sub> column into vol. flask. Rinse separator and column with enough *n*-heptane to dil. to vol.

**29.073****Thin Layer Chromatography**

Pre-sat. tank contg liner with *n*-heptane  $\geq 1$  hr before use. Establish imaginary spotting line 3 cm from bottom edge of plate. For each intended spot, use tip of 100  $\mu$ L pipet to scratch mark in adsorbent layer just size of pipet tip. (Space spots evenly with max. of 7 spots including blank.) Spot 100  $\mu$ L each stock and limit std solns on extreme spots (one on far right and one on far left of plate). Spot 100  $\mu$ L *n*-heptane as blank and 100  $\mu$ L sample between std spots. Use same pipet for all spots, rinsing thoroly with *n*-heptane between applications. Keep size of spots uniform at 1.5–2 cm diam. by using following technic: Fill 100  $\mu$ L pipet past mark with soln to be spotted. Carefully drain excess into absorbent towel until soln is at exact vol. mark. Press pipet tip against exposed glass in center of spotting mark on plate (hold pipet in vertical position at all times). Regulate size of spot by holding finger over top of pipet and pressing tip tightly against plate. Blow across spot (orally) only when necessary to regulate size of spot and never lift pipet from place once spotting is begun.

Pour 10–15 mL *n*-heptane in tank trough, insert plate, and seal tank. Develop until solv. is within 2.5 cm from top of plate (ca 30 min). Remove plate, air dry few min, and view under UV light. Biphenyl appears as bright blue spot on yellow background.

If no biphenyl appears in sample, end analysis at this point. If biphenyl is found, remove spots from plate without delay. Score upper and lower extremes of biphenyl zone horizontally across plate. Score vertical lines in adsorbent between biphenyl spots to include approx. equal area in each rectangle, scribing same area for ref. spot. Use razor blade to scrape off, and discard all adsorbent below biphenyl zone and outside extreme vertical lines. Use absorbent tissue and alcohol to clean exposed glass thoroly. Carefully scrape adsorbent from one extreme rectangular zone onto glazed paper and transfer to funnel inserted in 10 mL vol. flask; do not use solv. to rinse paper. Rinse off razor blade into funnel with small portion of alcohol. Tip plate at angle to facilitate rinsing of scraped area into funnel and rinse with several small portions alcohol. Rinse funnel and finally dil. to vol. with alcohol. Shake mixt. vigorously and let stand 5 min, shaking occasionally. Remove each biphenyl spot same way, working inward from each side of plate and cleaning and drying each previously removed zone. Filter each mixt. thru Whatman No. 44 paper, or equiv., and store filtrate in stoppered vessel for spectrophotric detn.

**29.074****Spectrophotometry**

Det. A of each soln at 248 and 300 nm in 1 cm cell with alcohol as ref.

ppm Biphenyl =  $(\Delta A_{248} \text{ sample} / \Delta A_{248} \text{ std}) \times (\mu\text{g std spotted/g sample spotted})$ , where  $\Delta A_{248} = A_{248} - [A_{300} \times (A_{248} \text{ blank} / A_{300} \text{ blank})]$ .

**29.075 ★ 2-(*p*-*tert*-Butylphenoxy)-1-Methylethyl ★  
2-Chloroethyl Sulfite (Aramite®) (75)  
Official Final Action**

Aramite is stripped from sample with benzene, soln is concd, and Aramite is hydrolyzed with KOH-isopropanol to form ethylene oxide. Evolved ethylene oxide is converted to HCHO with KIO<sub>4</sub>, and HCHO is reacted with acetylacetone to form colored compd. which is detd. colorimetrically. See 29.067–29.071, 12th ed.

**Captan (N-(Trichloromethylthio)-4-Cyclohexene-1,2-Dicarboximide) (76)—Official Final Action**

(Applicable to firm fruits such as apples, pears, peaches, and plums and to green vegetables)

**29.076 Principle**

Captan is extd from crop with benzene; H<sub>2</sub>O, color, and appreciable amts of waxes are removed, and red color is developed by fusion of captan with resorcinol at 135°; color changes to yellow on addn of HOAc.

**29.077 Reagents**

(a) *Resorcinol*.—Must be free of discoloration and pass following tests: Fuse 0.5 g and dissolve in 25 mL HOAc. *A* at 425 nm is ≤0.015, against HOAc. 1.00 g should not lose >2 mg in 4 hr over H<sub>2</sub>SO<sub>4</sub>; if more is lost, dry over H<sub>2</sub>SO<sub>4</sub> until test is satisfactory.

(b) *Cleanup mix*.—10 parts Nuchar, 5 parts Hyflo Super-Cel, and 5 parts anhyd. Na<sub>2</sub>SO<sub>4</sub>.

(c) *Captan std solns*.—(1) *Stock soln*.—3 mg/mL. Transfer 150 mg pure captan (available from Chevron Chemical Co., 940 Hensley St, Richmond, CA 94804) to 50 mL vol. flask and dil. to vol. with benzene. (2) *Intermediate soln*.—300 µg/mL. Pipet 10 mL stock soln into 100 mL vol. flask and dil. to vol. with benzene. (3) *Working soln*.—30 µg/mL. Pipet 10 mL intermediate std soln into 100 mL vol. flask and dil. to vol. with benzene.

**29.078 Preparation of Sample**

(Caution: See 51.039, 51.040, and 51.045.)

(a) *Fruits*.—Accurately weigh ca 500 g sample into clean, dry jar with screw cap faced with sheet cork gasket covered with wet filter paper, or other solv.-tight lid, and add 500 mL benzene. Multiples of sample-to-benzene ratio can be used. Agitate 15 min, drain benzene into container, and transfer to separator. (Transfer to separator may be omitted where there is no separable aq. layer.)

Transfer ca 100 mL sepd benzene layer to 250 mL g-s flask, and decolorize and dehydrate with 3–4 g cleanup mix, (b), by shaking vigorously ca 5 min. Filter thru folded paper, rejecting first 10–15 mL.

(b) *Green vegetables*.—Chop sample in food chopper such as Hobart Food Cutter, mix, and transfer 100 g to explosion-proof blender. Add 200 mL benzene and blend 2 min; add 20 g anhyd. Na<sub>2</sub>SO<sub>4</sub> and blend 2 min more. Pour mixt. into 500 mL centrf. bottle, stopper with cork, and centrf. at ca 1400 rpm 5–10 min. Decant benzene layer into 250 mL g-s erlenmeyer, add ca 6 g cleanup mix, (b)/100 mL benzene, and shake vigorously ca 5 min. Filter thru folded paper, discarding first 10 mL. If water-white soln does not result, repeat cleanup treatment. Pipet 50 mL into 100 mL vol. flask and dil. to vol. with benzene.

★ Surplus method—see inside front cover.

**29.079 Determination**  
(Caution: See 51.018, 51.040, 51.041, and 51.045.)

Pipet 5 mL filtrate, 29.078(a), or aliquot, (b), into 25 × 200 mm test tube and add 0.5±0.1 g resorcinol. Heat 20 min in oil bath at 135±5°, cautiously at first to evap. benzene; then immerse reaction tubes to depth of ca 5 cm but do not let them touch bottom of bath. Remove, and immediately add 10–15 mL HOAc, followed by rapid immersion in H<sub>2</sub>O at room temp. Transfer quant. to 25 mL vol. flask, using HOAc, dil. to vol. with HOAc, and mix.

Det. *A* at 425 nm in 1 cm cell against HOAc within 1 hr. Calc. ppm from std curve.

**29.080 Preparation of Standard Curve**

Prep. std curve simultaneously with samples. Pipet 0, 2, 4, and 5 mL aliquots of working std soln into 25 × 200 mm test tubes and add benzene to make total vol. of 5 mL in each tube. Add 0.5±0.1 g resorcinol and continue as in detn, beginning "Heat 20 min in oil bath . . ."

*Note*: One drop H<sub>2</sub>O in reaction tube will cause apparent loss of ca 20% captan. Do not leave benzene aliquots in unstoppered reaction tubes where condensation of moisture will take place.

**Carbaryl (1-Naphthyl N-Methylcarbamate) (Sevin®)  
Official Final Action**

**29.081 Multiple Residue Method**

See 29.058–29.063.

**Colorimetric Method (17)**

**29.082 Reagents**

(a) *Acetone*.—Redistd.

(b) *Coagulating soln*.—Dissolve 0.5 g NH<sub>4</sub>Cl in 400 mL H<sub>2</sub>O contg 1 mL H<sub>3</sub>PO<sub>4</sub>.

(c) *Color reagent*.—Dissolve 25 mg *p*-nitrobenzene-diazonium fluoborate in 5 mL MeOH and add 20 mL HOAc. Prep. just before use.

(d) *Methylene chloride*.—Redistd CH<sub>2</sub>Cl<sub>2</sub>.

(e) *Alcoholic potassium hydroxide soln*.—0.1N in MeOH.

(f) *Polyethylene glycol soln*.—Dil. 1 mL polyethylene glycol to 100 mL with CH<sub>2</sub>Cl<sub>2</sub>.

(g) *Carbaryl std solns*.—Ref. std material is available from Union Carbide Corp., PO Box 1906, Salinas, CA 93901. (1) *Stock soln*.—0.5 mg/mL. Place 50.0 mg in 100 mL vol. flask and dil. to vol. with CH<sub>2</sub>Cl<sub>2</sub>. (2) *Intermediate soln*.—50 µg/mL. Transfer 10 mL stock soln to 100 mL vol. flask and dil. to vol. with CH<sub>2</sub>Cl<sub>2</sub>. (3) *Working soln*.—5.0 µg/mL. Transfer 10 mL intermediate soln to 100 mL vol. flask and dil. to vol. with CH<sub>2</sub>Cl<sub>2</sub>.

**29.083 Apparatus**

*Evaporative concentrator*.—See Fig. 29.07. Vac. manifold connected thru stopcock to antisurge column, 250 × 19 mm od, contg glass marble, or Snyder column, attached to 24/40 erlenmeyer. Use surgical tubing wherever contact with sample is likely.

**29.084 Preparation of Sample Solution**

Transfer 50 g sample to high-speed blender and add 150 mL CH<sub>2</sub>Cl<sub>2</sub> and 100 g powd anhyd. Na<sub>2</sub>SO<sub>4</sub>. Blend at high speed 2 min and let settle 1 min. Decant solv. into 9 cm buchner fitted with Whatman No. 1, or equiv., paper covered with thin coat of Hyflo Super-Cel, or equiv., filter aid. Cautiously apply vac. until all solv. has filtered. Repeat extn with two 100 mL portions CH<sub>2</sub>Cl<sub>2</sub>. Treat combined filtrates as in (a) or (b):

Place trough in chromatgc tank lined with blotting paper. Add ca 50 mL acetone-benzene soln (1+4) to bottom of tank to sat. atm., and then add 50 mL same soln to trough. Place plate in trough and seal tank with masking tape. Develop plate until solv. front just reaches line drawn 10 cm from origin. Dry plate ca 15 min in hood. Spray moderately with 1.0*N* alc. KOH soln. Then spray moist plate with chromogenic soln. Blue spot with *R<sub>f</sub>* value same as std carbaryl spot indicates carbaryl (*R<sub>f</sub>* range, 0.52–0.60). Compare size and intensity of sample and std spots for semiquant. estn of amt of pesticide. It is possible to distinguish, for example, between 0.2 and 0.4 µg, but not between 0.3 and 0.4 µg. Optimum range for quant. estn is ca 0.1–0.4 µg. For amts >0.4 µg, spot smaller aliquot of remaining 80 µL soln. Then spot same vol. of std soln for valid comparison.

**29.091 ★ *p*-Chlorophenyl Phenyl Sulfone (*p*-CIDPS; ★ Sulphenone®) (19)—Official Final Action**

Hexane strip solns are extd with CH<sub>3</sub>CN, which seps Sulphenone components from bulk of waxes, coloring matter, and to some extent from other pesticides. The CH<sub>3</sub>CN residue is chromatographed on Magnesol column with hexane-anhyd. ether. Residue of fraction contg *p*-CIDPS is dissolved in isooctane for detn of UV *A*.

See 29.075–29.081, 11th ed.

**Diethyl Diphenyl Dichloroethane (Perthane) (20)—Official Final Action**

(For low levels (less than ca 50 ng/GLC injection) and for confirmatory quantitation of higher levels of Perthane previously detd by 29.001–29.018)

**29.092**

**Principle**

Method is extension of general method for multiple residues, 29.001–29.018. After electron capture GLC detn of Perthane and other organochlorine and organophosphorus pesticides, Perthane in 6% mixed ether eluate, 29.015, is dehydrochlorinated to its olefin. Perthane olefin is extd from reaction mixt. into hexane and portion of hexane is injected into gas chromatograph with electron capture detector. Perthane olefin produces 10-fold increase in electron capture detector response over that of parent compd.

**29.093**

**Reagents**

- Hexane.—See 29.002(j).
- Carborundum chips.—SiC, ca 20 mesh.
- Alcoholic potassium hydroxide soln.—Dissolve 2 g KOH in 100 mL alcohol.
- Perthane std soln.—50 µg/mL hexane. Perthane available from Rohm & Haas Co.
- Perthane olefin std soln.—5 µg/mL hexane.

**29.094**

**Apparatus**

- Reaction tube.—12 or 15 mL graduated centr. tube with No. 13 glass stopper (Corning Glass Works, No. 8084, or equiv.).
- Heat source.—Oil bath (100 mL beaker contg 80 mL paraffin oil) and mag. stirrer hot plate calibrated to maintain oil temp. at 100±5°.

**29.095**

**Determination**

After electron capture GLC of Perthane and other organochlorine and organophosphorus pesticides, 29.001–29.018, pipet entire 6% eluate, 29.015, or aliquot contg ≤30 µg Perthane into

reaction tube. Carefully evap. to dryness under gentle air current. Add 2 mL alc. KOH soln and 2–5 SiC chips. Place reaction tube in 100° oil bath to depth of ca 1.0 mL graduation and let soln reflux 15 min. (Conduct reaction in hood. Air flow thru hood will cool upper part of tube, which serves as condenser. Hood also removes odors escaping from hot oil.) Remove tube from oil bath, cool to room temp., and add 3 mL H<sub>2</sub>O. Pipet vol. hexane (but ≥1 mL) into tube to give concn ca 5 µg Perthane olefin/mL. Shake vigorously ca 30 sec and let layers sep. Det. Perthane olefin in hexane layer as in 29.018.

$$\text{ppm Perthane} = [(R \times W') / (R' \times W)] \times (307.25 / 270.78),$$

where *R* and *R'* = responses to Perthane olefin in sample and std, resp.; *W'* = ng std injected; *W* = mg equiv. sample injected; and 307.25 and 270.78 = MW Perthane and Perthane olefin, resp.

**Dichloro Diphenyl Trichloroethane (DDT) (1,1,1-Trichloro-2,2-bis(chlorophenyl)ethane) Official Final Action**

**29.096**

**Multiple Residue Method**

See 29.001–29.028.

**★ Colorimetric Method (21) ★**

**29.097**

**Principle**

Com. DDT consists essentially of 2 isomers, *p,p'*- and *o,p'*-DDT, in proportion of ca 3:1. Dry isomers of DDT can be nitrated to tetranitro DDT, which can be extd by ether, dried, and taken up in measured vol. benzene. Treating this soln with stdzd anhyd. NaOMe soln produces reasonably stable colors—blue for *p,p'* and reddish purple for *o,p'* isomer. This reaction (Schechter-Haller) is fairly specific for DDT. Exceptions are nitrated or dehalogenated decomposition products of DDT and certain close analogs that can produce yellow to red and sometimes blue colors with NaOMe. If distinctly "off" colors are produced on samples of unknown spray history and cannot be removed from solv. by careful washing with alkali, analogs may be present, and special methods for their detection must be applied.

Principal known interfering insecticides are TDE (1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethane), methoxychlor (1,1,1-trichloro-2,2-bis(*p*-methoxyphenyl) ethane), DNB and DNP (2-nitro-1,1-bis(*p*-chlorophenyl)butane and propane analogs of DDT). Other insecticidal compds, as well as limited amt of benzene-sol. plant extractives, are oxidized or degraded in nitration and are then removed from ether or pet ether soln by washing with alkali, or they do not react under conditions of method. Other org. material does not seriously interfere, but if >100 mg of extraneous org. matter is present, as in fats, special sepsns must be made.

**29.098**

**Preparation of Sample**

(Caution: See 51.004, 51.011, 51.039, 51.040, 51.043, 51.045, and 51.073.)

(a) For all fresh or frozen fruits and vegetables, meat, and canned food except milk, and for all soft or wet materials generally: Beans (green), broccoli, brussels sprouts, cauliflower, cabbage, cherries, cranberries, grapes, lettuce, pea pods, spinach, squash, tomatoes, silage, etc.—Finely chop 1 kg sample or entire contents of small unit package in suitable food chopper (powered mech. food chopper such as Hobart is satisfactory) and transfer well mixed 100 g portion to high-speed blender. Add 100 mL isopropanol and blend 2 min. Add 200 mL hexane or benzene and blend again 2 min. (To avoid splashing and

★ Surplus method—see inside front cover.

possible loss of sample, regulate blending speed with rheostat or variable transformer when necessary.)

Pour mixt. as completely as possible into 600–800 mL beaker and let solids settle. Pour solv. layer equally into two 250 mL centr. bottles. With aid of stirring rod and funnel, distribute solid material equally between the 2 bottles. Stopper and centr. 5 min at ca 1500 rpm. If solids pack firmly, decant supernate directly into 500 mL vol. flask. If solids pack loosely, transfer liq. thru siphon tube, **16.220, Notes**. Wash blender cup, cap, and beaker with two 100 mL portions isopropanol-hexane or -benzene (1+2). Distribute washings equally between the 2 bottles. Break up solid material with stirring rod, stopper bottles, and shake vigorously 2 min. Centr. as before and add solv. layer to vol. flask. Dil. to vol. with isopropanol-hexane or -benzene (1+2). (Final soln should be clear.)

(b) *For hay, cured (dry).*—Chop 1 kg sample and mix well. Grind portion in Wiley or other mill to ca 20 mesh.

Measure 500 mL extg solv. (350 mL H<sub>2</sub>O dild to 1 L with CH<sub>3</sub>CN, **29.002(a)**, and mixed in graduate). Pour ca 350 mL into high-speed blender, add 50 g sample, and blend 2 min. Add remainder of extg solv. (total 500 mL) and blend addnl 3 min at highest speed attainable without splashing. Filter with vac. thru powder funnel contg wad of glass wool and press out free liq. with back of large spoon or other means. Measure and record vol. filtrate, and transfer to 2 L separator. Add 200 mL pet ether (boiling range 30–60°), and shake vigorously 1–2 min. Add ca 20 mL satd NaCl soln and ca 1200 mL H<sub>2</sub>O, and mix gently but thoroly. Re-ext aq. layer with two 100 mL portions pet ether. Discard aq. layer, swirl combined pet ether, drain off any aq. phase closely, and transfer exts to beaker. Evap. just to dryness on steam bath with aid of gentle air current.

Wt sample represented in analysis = wt sample taken × vol. filtrate/vol. extg solv. added.

(c) *For flour, cereals, feeding stuffs, or other comparatively fine dry materials.*—Ext 25 g sample with ether or benzene in Soxhlet app. or shake larger samples with suitable amts of solv. in centr. bottle, centr., and decant solv. Repeat extn once or twice, according to size sample. If necessary, sep. fat and DDT as in (d), and det. DDT in ext by colorimetric method.

(d) *For milk, cream, cheese, butter, oils or fats, etc.*—As DDT is dissolved in fat phase of dairy products, first sep. fats as in **29.012**, then isolate DDT as in **29.014**, and det. by colorimetric method (3 g fat is upper limit). Proceed as in **29.102(b)**.

## 29.099

(Caution: See **51.011** and **51.039**.)

## Reagents

(a) *Ether.*—Peroxide- and aldehyde-free.

(b) *Redistilled ether-petroleum ether.*—(1+4).

(c) *Benzene.*—(Caution: See **51.045**.) Redistd. Distil until no more H<sub>2</sub>O comes over, and discard distillate; replace condenser with dry one, and collect balance of distillate.

(d) *Nitrating mixture.*—(Caution: See **51.026**, **51.030**, and **51.031**.) Mix fuming HNO<sub>3</sub> (sp gr 1.49–1.50) with equal vol. H<sub>2</sub>SO<sub>4</sub>. Chill before using.

(e) *Sodium methylate soln.*—1.74*N*. 40 g Na/L MeOH. (Caution: See **51.034** and **51.038**.) Prep. anhyd. MeOH as follows: Place 75 mL "absolute" MeOH in flask provided with reflux condenser and add 5 g clean Mg turnings. Add 0.5 g I<sub>2</sub> and warm gently, if necessary, until vigorous evolution of H sets in; then reflux until most of Mg has been converted to Mg(OMe)<sub>2</sub>. Add mixt. to ca 900 mL untreated MeOH, reflux 30 min, and distil with exclusion of atm. H<sub>2</sub>O. Preserve in tightly stoppered bottles. (Or dehydrate by refluxing 2–4 hr with 25 g CaH<sub>2</sub>/L and then distg.)

Place 20.0 g freshly cut Na in flask provided with reflux condenser and add enough purified MeOH portionwise thru

condenser to dissolve all the Na, warming and refluxing if necessary. Rinse into 500 mL vol. flask with addnl purified MeOH, cool, dil. to vol., and mix thoroly. Chill, centr. down any carbonate turbidity, and decant clear supernate into dispensing system that excludes atm. H<sub>2</sub>O and CO<sub>2</sub>. Adjust batches of NaOMe soln to std concn after titrn with std acid, and prep. new std curve for each batch as made.

Store in dispensing system with all outlets trapped against CO<sub>2</sub> and H<sub>2</sub>O and with inner delivery tube to buret packed with dry, alkali-treated asbestos to filter soln immediately before use.

(f) *Pure p,p' (mp 108–109°) and o,p' (mp 74–74.5°) DDT.*—*p,p'* Isomer may be prepd from 200 g tech. DDT by recrystg 2 or 3 times from alcohol, and *o,p'*-DDT from mother liquors by concn, fractional crystn from *n*-pentane, and recrystn from MeOH. *o,p'*-DDT may be synthesized as in J. Am. Chem. Soc. **67**, 1591(1945).

(g) *DDT std solns.*—(1) *Pure soln.*—0.2 mg total DDT (0.15 mg *p,p'* and 0.05 mg *o,p'*)/mL. Weigh 50 mg of the 2 pure isomers into 2 sep. 50 mL vol. flasks and dil. to vol. with benzene. Pipet 15 mL *p,p'* soln and 5 mL *o,p'* soln into 100 mL vol. flask and dil. to vol. with benzene. (2) *Technical soln.*—0.2 mg tech. DDT/mL benzene.

## 29.100

## Preparation of Standard Curves

(a) *For 0–1.0 mg range.*—Measure 0, 1.00, 2.00, 3.00, 4.00, and 5.00 mL of either std DDT soln into 50 mL erlenmeyers and evap. solv. on steam bath. Remove residual vapors with gentle air current, weight flasks (small Pb rings are convenient), and immerse in pan of ice-H<sub>2</sub>O. (Use pan shelved so that vessels do not rest directly on bottom; porcelain desiccator platform in pan of proper size makes convenient bath.) Thoroly chill flasks and to each slowly add 5 mL chilled nitrating mixt. Rotate flasks to wet all portions of residue; then place pan on hot plate or steam bath and heat so that solns reach ca 85° in 20–30 min. Remove flasks from pan, place directly upon active steam bath, and nitrate 30 min. Remove flasks and cool under tap or leave overnight.

Slowly pour chilled acid mixt. from each flask into separator contg ca 25 mL ice-cold H<sub>2</sub>O, rinse flask with several portions of ice-H<sub>2</sub>O, and pour rinsings into separator. Rinse again with 25 mL ether-pet ether (1+4), and finally with second 15 mL portion ether-pet ether (1+4), pouring last rinse into second separator. Ext by shaking first separator vigorously 1 min; then drain aq. layer into second separator and repeat extn. Discard aq. layer and drain second separator into first, rinsing with small portions of ether mixt. Bleed off any residual aq. layer as completely as possible, add 10 mL 10% KOH soln, and shake vigorously 30 sec. Drain off closely and wash with two 15 mL portions satd NaCl soln. Drain well and filter ext thru 1.2 cm layer of washed and dried glass wool previously wetted with ether mixt., held in filter tube, into 125 mL erlenmeyer contg glass bead. Rinse separator and filter with few small portions of ether mixt., evap. off ether on steam bath (gentle air current speeds evapn and controls bumping), and heat 1 hr at 100°.

Cool flask, making sure interior is thoroly dry, and take up residue with exactly 25 mL redistd benzene. Stopper flask and swirl 1 min to ensure complete soln of residue. (Procedure may be interrupted overnight at this stage.)

Transfer 5.00 mL aliquot to small flask and develop characteristic DDT color by adding exactly 10.0 mL NaOMe soln. Mix well, let stand 15 min, and then det. *A* at 600 nm in cell of appropriate length against benzene-NaOMe soln (1+2). (Readings in blue at 450 nm and in green at 510 nm should also be made to check presence of extraneous yellow and red colors

when actual samples are read later.) If instrument used records in terms of  $T$ , convert to  $A$  ( $-\log T$ ).

Measure all colors of series in same (or similar) cells and plot  $A$  against  $\mu\text{g}$  DDT on linear coordinate paper to obtain std curve. Stopper cells with glass covers or stoppers. If test tubes are used, close with clean cork stoppers. Either cells with optically fused ends or cells constructed with alkali-resistant cement may be used, but if cemented cells are used, do not leave alk. solns in cells longer than necessary to make measurements, and clean cells immediately after use.

(b) *For 0–50  $\mu\text{g}$  range.*—Add 0, 10, 20, 30, 40, and 50  $\mu\text{g}$  DDT, in benzene soln, to series of 50 mL erlenmeyers, each contg 10 mg oleic acid in benzene soln, and evap. to dryness. (Small Pb rings are convenient for weighting flasks. Oleic acid serves as inert “keeper” material to prevent loss of micro amts of DDT.) Nitrate as in (a) and ext with redistd pet ether. Wash ext 3 times with 10% KOH soln, shaking vigorously 2 min each time. Heat final washed residues 1 hr at  $100^\circ$ , take up in 3.00 mL redistd benzene, and develop color with 6.00 mL of the NaOMe soln. Plot  $A$  against  $\mu\text{g}$  DDT as in (a).

## 29.101

### Removal of Coloring Matter

(Caution: See 51.011, 51.030, 51.031, 51.039, 51.040, 51.045, 51.049, and 51.054.)

(a) *Applicable to extracts of fruits, vegetables, and most other low-fat products.*—Evap. 200 mL aliquot prepd soln, 29.098(a), or suitable aliquot of 29.098(c), just to dryness in 400 mL beaker on steam bath with aid of small air current. Dissolve residue in 10 mL  $\text{CCl}_4$  and transfer to column prepd as follows:

Grind 10 g Celite 545 thoroly with 3 mL 15–20% fuming  $\text{H}_2\text{SO}_4$  in mortar, add 3 mL  $\text{H}_2\text{SO}_4$ , and grind well. Transfer at once to fritted glass funnel or tube (funnel: 40 mm id, 60 mL capacity, coarse porosity; tube: 30 mm disk, 130 mL capacity, coarse porosity (sulfur absorption tube, Arthur H. Thomas Co. No. 8815-K10 is satisfactory)). Pack adsorbent to firm level surface with flat-end glass rod. Add  $\text{CCl}_4$  to column to wet adsorbent and let solv. drain until ca 2 mm layer remains on top of column.

Transfer 10 mL  $\text{CCl}_4$  sample soln to column. Rinse sample beaker with three 10 mL portions  $\text{CCl}_4$  and add rinsings to column. Collect eluate in 125 mL g-s flask. Let solv. drain until level just reaches surface of adsorbent and rinse walls of tube with 10 mL  $\text{CCl}_4$ . Repeat with second 10 mL portion  $\text{CCl}_4$ . After solv. drains to surface level, add 25 mL  $\text{CCl}_4$  and let drain completely. At no time permit solv. to sink entirely into column (go dry) until this point is reached. Tamp surface of column with flat-end glass rod to remove all free liq.

(b) *Applicable to extracts of hay.*—Proceed as in (a), except use 20 g Celite 545 with 6 mL 15–20% fuming  $\text{H}_2\text{SO}_4$  and 6 mL  $\text{H}_2\text{SO}_4$  for column, and 170 mL  $\text{CCl}_4$  for elution.

(c) *Applicable to extracts of fatty materials containing maximum of 3 g fat.*—Proceed as in (a), except use 30 g Celite 545 with 9 mL 15–20% fuming  $\text{H}_2\text{SO}_4$  and 9 mL  $\text{H}_2\text{SO}_4$ , and 250 mL  $\text{CCl}_4$  for elution.

## 29.102

### Determination

(Caution: See 51.011, 51.039, 51.040, and 51.054.)

(a) *Applicable to extracts of fruits, vegetables, and other low-fat products.*—Evap. solv. to dryness on steam bath with aid of small air current. Carefully nitrate residue as in 29.100(a). To ensure thoro removal of interfering oxidn byproducts, wash ether mixt. with six 10 mL portions 10% KOH soln.

If amt of DDT is unknown, develop exploratory color with 5 mL aliquot and 10 mL NaOMe soln. If  $A$  is  $<0.20$ , check by taking 10–15 mL aliquot, evapg to dryness, redissolving in 5 mL benzene, and developing color; if  $A$  is  $>0.80$ , check by taking

smaller aliquot, dilg to 5 mL with benzene, and developing color. In all cases, even if exploratory  $A$  reading falls in range 0.20–0.80, develop color on another aliquot of nitrated sample as check.

Det.  $A$  of final soln at 600 nm and also take readings at 510 and 450 nm to det. if gross amts of interfering red or yellow are present. Obtain total DDT in aliquot from std curve and calc. total DDT in sample in ppm.

(b) *Applicable to extracts of fatty materials containing maximum of 3 g fat.*—Proceed as in (a), except use all of nitrated sample to develop color, and use 0–50  $\mu\text{g}$  std curve method, 29.100(b).

## Dichlone (2,3-Dichloro-1,4-naphthoquinone) (Phygon®) (22)—Official Final Action

(Applicable to fresh fruits and vegetables)

## 29.103

### Reagents

(a) *Dichlone std soln.*—0.2 mg/mL. Dissolve and dil. 40 mg dichlone (Eastman Kodak Co. No. 3836, or equiv.) to 200 mL with benzene.

(b) *Dimethylamine.*—25% aq. soln (Eastman Kodak Co. P601 or equiv.).

(c) *Florisil.*—60/100 mesh, PR Grade, activated at  $1250^\circ\text{F}$  (Floridin Co.). Heat  $\geq 4$  hr at  $130^\circ$  and store in stoppered flasks in desiccator prior to use.

## 29.104

### Preparation of Standard Curve

Place 0, 1.00, 2.00, 3.00, 4.00, and 5.00 mL dichlone std soln in 25 mL g-s graduates and dil. each to 10 mL with benzene. To each graduate add isopropanol to 20 mL mark and mix. Add 1 mL 25%  $\text{Me}_2\text{NH}$  soln, dil. to 25 mL with isopropanol, and mix.

Read  $A$  of stds against blank in covered 1 cm cells at 495 nm, and plot  $A$  against mg dichlone (0–1.0 mg range). Color is stable  $>1$  hr.

## 29.105

### Preparation of Column

Fill  $15 \times 300$  mm chromatgc tube, fitted with fritted glass disk or glass wool plug, with Florisil to ca  $\frac{1}{3}$  its length. (No stopcock is required.) Prewet Florisil with 30 mL benzene.

## 29.106

### Determination

(Caution: See 51.011, 51.039, 51.040, and 51.045.)

Strip weighed sample (ca 1 kg) with 500 mL benzene by gently turning or tumbling 10 min in suitable container (ca 4 L; 1 gal.). (Avoid breaking plant tissue.) Drain benzene into 1 L flask thru folded paper (ca 32 cm) contg ca 50 g anhyd.  $\text{Na}_2\text{SO}_4$ .

Add 200 mL dried benzene strip soln to prepd chromatgc column. Discard benzene eluate. Elute dichlone from column with 100 mL acetone-benzene eluting mixt. (1+99). Collect eluate in beaker and evap. to ca 15 mL. (Do not let sample overheat or go to dryness.) Rinse sample into graduate and dil. to 20 mL with benzene. Develop color in 10 mL of this soln as in 29.104.

mg Dichlone from std curve  $\times 5$  = ppm dichlone (for 1 kg sample).

If visible color is present in benzene eluate, simultaneously develop color in remaining 10 mL aliquot, omitting  $\text{Me}_2\text{NH}$  and adding 1 mL  $\text{H}_2\text{O}$ . Subtract this blank  $A$  from that of developed sample to correct for sample blank.

★ *O,O*-Dimethyl *S*-(4-Oxo-1,2,3-benzotriazin-3-(4H)-yl Methyl) Phosphorodithioate (Guthion®) (23)—Official First Action

(Applicable to cole-type crops and to apples, plums, peaches, grapes, apricots, and cherries.)

**29.107**

Guthion is extd from crop with acetone and reextd with  $\text{CHCl}_3$  from acetone after diln with  $\text{H}_2\text{O}$ . Solv. is removed by evapn; residue is dissolved in isopropanol and cleaned up on chromatgc column. Guthion is hydrolyzed in alk. soln to anthranilic acid, which is diazotized and coupled with *N*-(1-naphthyl) ethylenediamine.2HCl to form colored compd. Omission of alk. hydrolysis reveals presence of interfering materials except Et homolog of Guthion. See 29.102–29.107, 12th ed.

**Dodine (Cyprex®) (Dodecylguanidine Acetate) (DDGA) (24)—Official Final Action**

(Applicable to apples, peaches, pears, pecans, and strawberries)

**29.108**

**Reagents**

(a) *Bromocresol purple soln.*—Recrystallize indicator-grade bromocresol purple from boiling toluene (ca 2 g/100 mL). Dissolve 0.4 g recrystd material in 75 mL 0.01*N* NaOH; if necessary, add addnl 0.01*N* NaOH to bring pH to 6.0–6.1. Filter, if necessary, and dil. to 500 mL with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ . Store in brown bottle.

(b) *Buffer soln.*—pH 5.5. Dissolve 15.2 g  $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$  and 74.0 g  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$  in  $\text{CO}_2$ -free  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) *Dodecylguanidine acetate (DDGA) std solns.*—(1) *Stock soln.*—130  $\mu\text{g}/\text{mL}$ . Dissolve 32.5 mg Ref. Std (available from American Cyanamid Co.) in MeOH and dil. to 250 mL with MeOH. (2) *Working soln.*—13  $\mu\text{g}/\text{mL}$ . Dil. 25 mL aliquot stock soln to 250 mL with MeOH.

**29.109**

**Preparation of Sample**

Grind sample in high-speed blender with MeOH- $\text{CHCl}_3$  (2+1) in ratio of 400 mL solv./100 g sample. Filter with suction thru 2 Whatman No. 1, or equiv., papers in buchner, and wash pulp with MeOH- $\text{CHCl}_3$  (2+1), using 100 mL/100 g sample. Det. vol. of ext and transfer portion equiv. to 50 g sample to 400 mL beaker.

**29.110**

**Determination**

Add several glass beads and 1 mL HCl to beaker, and evap. to 50 mL on steam bath. Add 30 mL 30% NaCl soln and 100 mL MeOH. Cool, transfer to 500 mL separator, and ext gently with 50 mL  $\text{CCl}_4$  by inverting separator 6–8 times. Let phases sep. and discard  $\text{CCl}_4$  layer. Repeat with 50 mL  $\text{CCl}_4$ , inverting separator ca twice as many times. Discard  $\text{CCl}_4$ ; then ext with 50 mL  $\text{CCl}_4$ , shaking gently 30 sec. Finally, ext with 50 mL  $\text{CCl}_4$ , shaking vigorously 1 min, and again discard  $\text{CCl}_4$ .

Adjust pH of soln to ca 5.5 with 4*N* NaOH (pH meter), and add 20 mL pH 5.5 buffer and 20 mL bromocresol purple soln. Re-adjust pH to 5.5 and ext complex with two 50 mL portions  $\text{CHCl}_3$ , shaking 2 min each time. Shake combined ext 30 sec with 25 mL pH 5.5 buffer, and transfer  $\text{CHCl}_3$  layer to another separator. Shake 1 min with 25 mL pH 5.5 buffer, let stand 10 min, and transfer  $\text{CHCl}_3$  to another separator. Shake with 20 mL 0.05*N* NaOH to remove all combined indicator and any org. acids which may persist. Recomplex dodecylguanidine (in  $\text{CHCl}_3$  as free base) by shaking 3 min with 5 mL bromocresol purple soln and 20 mL pH 5.5 buffer. Wash  $\text{CHCl}_3$  with three 15 mL portions

pH 5.5 buffer, shaking 1 min each time. Transfer  $\text{CHCl}_3$  to dry 250 mL separator and shake 2 min with 20 mL 0.05*N* NaOH, measured by pipet. Read *A* of indicator in aq. soln at 590 nm, using Beckman spectrophtr, or equiv. Obtain  $\mu\text{g}$  DDGA from std curve.

**29.111**

**Preparation of Standard Curve**

Add 0.5, 1.0, 2.0, 3.0, 4.0, and 5.0 mL std soln to series of separators contg 100 mL MeOH, 50 mL  $\text{H}_2\text{O}$ , 30 mL 30% NaCl soln, 20 mL bromocresol purple soln, and 20 mL pH 5.5 buffer. Adjust pH of each soln to 5.5 and continue as in 29.110, par. 2, beginning "... and ext complex with two 50 mL portions  $\text{CHCl}_3$ , shaking 2 min each time." Read *A* of each aq. soln at 590 nm and plot against  $\mu\text{g}$  DDGA. No blank correction is necessary for stds.

ppm DDGA =  $\mu\text{g}$  DDGA in aliquot/g sample in aliquot.

**Ethylenethiourea (ETU)**

**Gas Chromatographic Method (25)**

**Official First Action**

(Applicable to potatoes, spinach, applesauce, and milk. *Caution:* See 51.056 and 51.066.)

**29.112**

**Apparatus**

(a) *Chromatographic tube.*—Glass, 300 × 22 (id) mm, with coarse fritted disk and Teflon stopcock.

(b) *Filter paper.*—Sharkskin (Arthur H. Thomas Co., or equiv.).

(c) *Gas chromatograph.*—With flame photometric detector (Melo Laboratory, Inc., 6715 Electronic Dr, Springfield VA 22151, or equiv.) contg S filter and 1.8 m × 4 (id) mm coiled glass column packed with 5% Carbowax 20M plus 2.5% KOH (prepd in MeOH) on 80–100 mesh Chromosorb W(HP). Condition new column 2 days at 210°. Typical operating conditions—temps (°): column 180, injection port 185, detector 185; flow rates (mL/min): N carrier gas 60, O 15, air 125, H 200; electrometer sensitivity  $1 \times 10^{-9}$  amp full scale deflection with 1 mv recorder. Approx. retention time of S-butylated ETU under these conditions is 4 min; 12 ng gives ca 50% full scale deflection. Change glass wool plug in injection port daily before use, and clean out inside of column at injection port weekly.

(d) *High-speed blender.*—Waring Blendor, or equiv. (*Caution:* See 51.004.)

(e) *Pipets.*—Disposable glass capillary pipets, 145 × 6 (id) mm (Arthur H. Thomas Co., or equiv.).

(f) *Rotary evaporator.*—Use with 150 mm  $\Phi$  24/40 Vigreux column and place vac. release valve in line. (*Caution:* See 51.004.)

(g) *Silanized glass wool.*—Applied Science Laboratories, Inc., or equiv.

**29.113**

**Reagents**

(a) *Aluminum oxide.*—Fisher No. A-540, or equiv., 80–200 mesh, for chromatgc adsorption. (Available from Fisher Scientific Co. as "Alumina, Adsorption, Fisher.") Use as received.

(b) *1-Bromobutane.*—Fisher Scientific Co., or equiv. Redistill between 101 and 101.5°.

(c) *Diatomaceous earth.*—Celite 545. Do not acid-wash.

(d) *Eluant.*—4% alcohol in  $\text{CHCl}_3$ . Dil. 40 mL alcohol to 1 L with  $\text{CHCl}_3$ , and mix well.

(e) *Solvents.*— $\text{CHCl}_3$ , MeOH, and toluene, distd in glass (see statement regarding solvs, 29.001).

(f) *Ethylenethiourea std solns.*—(1) *Stock soln.*—10  $\mu\text{g}$  ETU/mL. Transfer 100 mg ETU ref. std (available from Pesticide Reference Standards Section, Registration Division, Environ-

★ Surplus method—see inside front cover.

mental Protection Agency, 401 M St, SW, Washington, DC 20460) to 100 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Pipet 1 mL this soln into another 100 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Prep. fresh monthly. (2) *Working soln.*—2 µg ETU/mL. Pipet 10 mL stock soln into 50 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Prep. fresh weekly.

**29.114****Extraction**

(Samples must be started and completed on same day.)

(a) *For crops, canned goods, and milk.*—Blend 100 g chopped crop (vegetables and fruits) or 100 g milk, 150 mL H<sub>2</sub>O, 15 g NaCl, 10 g diat. earth, (c), and 200 mL MeOH in high-speed blender 2 min. Filter with vac. thru 1.3 cm bed of diat. earth spread dry and evenly on 9 cm double sharkskin filter paper in 91 mm (id) buchner. Transfer 87 mL (20 g) aliquot to previously weighed 500 mL  $\frac{25}{24/40}$  r-b flask. Add 50–70 mL MeOH, insert Vigreux column into flask, and conc. on rotary vac. evaporator immersed in 60–65° H<sub>2</sub>O bath. If substantial initial frothing occurs, add 4–5 drops octanol. If much frothing occurs during last stages of concn, add addnl 4–5 drops octanol, 25 mL alcohol, or both. Conc. to ca 10 g. Disconnect flask, weigh, and add enough H<sub>2</sub>O to bring wt to 13 g. Proceed immediately as in 29.115.

(b) *Optional extraction for crops.*—(Applicable when presence of parent ethylenebisdithiocarbamate (EBDC) fungicide is suspected in sample. Provides measure of potential ETU residues which may be converted from EBDCs in home cooking.) Place 100 g chopped crop, 150 mL H<sub>2</sub>O, and 1 mL NH<sub>4</sub>OH in 1 L beaker, and record total wt. Cover with large watch glass, place on 600–720 watt hot plate turned to high, and heat 15 min, reducing heat to low after initial boiling. Cool, remove watch glass, and reweigh. Add H<sub>2</sub>O to beaker to restore to original wt. Transfer quant. to high-speed blender, using 200 mL MeOH. Add 10 g diat. earth, (c), and blend 20 sec. Proceed as in (a), beginning "Filter with vac. thru 1.3 cm bed . . .", except conc. sample to ca 8 g and add H<sub>2</sub>O to bring wt to 10 g. Proceed immediately as in 29.115.

(c) *Optional extraction for milk.*—(Applicable when presence of parent EBDC fungicide is suspected in sample.) Place 100 g milk, 25 mL H<sub>2</sub>O, 5 g NaCl, and 1 mL NH<sub>4</sub>OH in 1 L beaker, and record total wt. Proceed as in (b), beginning "Cover with large watch glass, . . ." except use 275 mL MeOH, stir thoroly 1 min, and, after filtering, transfer 80 mL (20 g) aliquot to r-b flask. Proceed immediately as in 29.115.

**29.115****Cleanup**

Add 10 g Gas-Chrom S to sample ext, stopper, and shake vigorously until lump-free (30–60 sec), tapping on cork ring, if necessary. Add 50 mL eluant, (d), stopper, and shake 1–2 min. Pour mixt., including as much of Gas-Chrom S as possible, into chromatgc tube, 29.112(a), contg 4–5 g Al<sub>2</sub>O<sub>3</sub>, (a), held in place with 1.3 cm glass wool plug. Rinse flask with 3 addnl 50 mL portions eluant, adding each rinse to tube. Collect eluate in 500 mL  $\frac{25}{24/40}$  r-b flask contg 10 mL H<sub>2</sub>O and 20 mL alcohol. Conc. eluate to ca 20 mL using rotary vac. evaporator with Vigreux column. Add 5 mL H<sub>2</sub>O and 20 mL alcohol, and conc. to 10 mL to eliminate CHCl<sub>3</sub>. Rinse column and flask with 5 mL H<sub>2</sub>O followed by 20 mL alcohol. Proceed immediately as in 29.116.

**29.116****Derivatization**

(a) *Sample.*—To sample flask add 1.5 g KOH, 2 mL I-bromobutane, (b), and 5–6 boiling chips. Reflux on pre-heated hot plate 10 min, using cold H<sub>2</sub>O condenser and clamp to support flask. Cool, and transfer quant. to 250 mL separator with 10 mL H<sub>2</sub>O followed by 50–60 mL CHCl<sub>3</sub>. Shake 1–2 min, and let layers

sep. completely (ca 5 min). Collect lower CHCl<sub>3</sub> layer in clean 250 mL  $\frac{25}{24/40}$  r-b flask. Add 2 drops HCl and evap. to near dryness on rotary vac. evaporator, using Vigreux column and 60–65° H<sub>2</sub>O bath. Rinse neck of flask with 2–3 mL MeOH, and evap. again on rotary evaporator. Remove flask and evap. to dryness, using air jet for 2–3 min. *All MeOH must be removed by this final evapn or it will interfere with GLC detn.* Remove flask from air jet, pipet in 1 mL toluene and add 1.0–1.5 mL 10% KOH, stopper, and shake 1–2 min. Remove 0.5–0.7 mL of toluene layer with disposable pipet, (e), without collecting any of lower aq. layer. Place toluene sample ext in clean, dry calibrated test tube, and record vol. At this point, 1 mL ext is equiv. to 20 g sample. However, if final ext is dild for GLC, vol. recorded with respect to original 1 mL toluene must be used for sample wt. calcsn:

Wt sample in final diln =

$$[(\text{vol. obtained from 1 mL}) / (1 \text{ mL toluene})] \times 20 \text{ g}$$

Do not conc. sample ext at this point due to volatility of butyl derivative of ETU.

(b) *Standard.*—Pipet 1 mL ETU working std soln into 500 mL  $\frac{25}{24/40}$  r-b flask. Add 15 mL H<sub>2</sub>O, 20 mL alcohol, 1.5 g KOH, 2 mL I-bromobutane, and 5–6 boiling chips, and proceed as in (a), beginning "Reflux on preheated hot plate . . ."

**29.117****Determination**

Initially, inject 4–6 µL std ext, 29.116(b), into gas chromatograph, and then inject 5 µL sample ext, 29.116(a). Adjust injection vol. of sample ext until peak hts of std and sample are approx. equal, and continue with alternate injections of sample and std. (S detector is non-linear; therefore, do not prep. std curve.)

$$\text{ETU, ppm} = (PH/PH') \times (W'/W),$$

where PH = peak ht of sample, PH' = peak ht of std, W' = ng ETU in std aliquot, and W = mg sample represented by sample aliquot.

**29.118****Regeneration of Gas-Chrom S**

Shake all used Gas-Chrom S from cleanup column, 29.115, into large beaker or flask. Discard Al<sub>2</sub>O<sub>3</sub> and glass wool plug. Wash thoroly with H<sub>2</sub>O, and decant after each wash. Wash thoroly with MeOH, decant, and vac. dry in large buchner. Air dry in hood and transfer to 80° oven overnight. Gas-Chrom S may now be re-used.

**2-Heptadecyl Glyoxalidine Acetate (Glyodin)****(26)—Official Final Action**

(Applicable to apples and pears. Not applicable to fruits with extensive softening or decomposition. All glassware must be free of soap or detergent.)

**29.119****Reagents**

(a) *Bromophenol blue soln.*—Prep. just before use. Transfer 50 mg bromophenol blue powder into 500 mL vol. flask with small amt of H<sub>2</sub>O. Add 2 mL HOAc and swirl until dye is completely dissolved. Dil. to vol. with H<sub>2</sub>O, and mix.

(b) *Glyodin std solns.*—Prep. from 2-heptadecyl glyoxalidine, purified grade (available from ICN-K&K Laboratories). (1) *Stock soln.*—1 mg/mL. Dissolve 100.0 mg 2-heptadecyl glyoxalidine in CHCl<sub>3</sub> in 100 mL vol. flask, dil. to vol. with CHCl<sub>3</sub>, and mix. (2) *Working soln.*—0.05 mg free base/mL. Transfer 5.0 mL stock soln to 100 mL vol. flask, dil. to vol. with CHCl<sub>3</sub>, and mix.

**29.120****Preparation of Standard Curve**

Add 0, 2, 4, 6, 8, and 10 mL working std soln to six 50 mL vol. flasks. Add exactly 1 mL HOAc to each flask and dil. to vol. with

$\text{CHCl}_3$ . Place 25 mL of each std, measured in graduate or fast-flow pipet, in 125 mL separator. Add 25 mL bromophenol blue soln, (a), from graduate or fast-flow pipet to each separator, and shake vigorously 1 min. Let sep.  $\geq 20$  min. Filter  $\text{CHCl}_3$  layer thru pledget of glass wool in stem of separator into small g-s erlenmeyer. Det. A at 415 nm in spectrophtr, using 1 cm cells and 0 std as ref. Plot A against mg 2-heptadecyl glyoxalidine.

### 29.121 *Preparation of Sample*

Fill tared wide-mouth gal. (3.8 L) glass jar with whole fruit so that little or no slack is present (to prevent battering of fruit). Weigh, and add 250 mL isopropanol. Screw cap on tightly with double thickness of cellophane placed over mouth of jar before cap is screwed on to help prevent leakage. Tumble or shake 10 min. Filter into 500 mL vol. flask thru small layer of glass wool in funnel. Drain off as much liq. as possible. Repeat stripping with second 250 mL portion of isopropanol, and filter into vol. flask. Wash glass wool and funnel with small portions of isopropanol and dil. to vol.

### 29.122 *Determination*

Transfer 25 mL aliquot of strip soln to 50 mL beaker and evap. to dryness on steam bath under air jet. To residue add exactly 1 mL HOAc, allowing acid to drip slowly down sides of beaker so that all residue is wetted. Cover beaker with watch glass and heat gently on steam bath with swirling, until residue at bottom loosens and disintegrates. Thoroly rinse down sides with few mL  $\text{CHCl}_3$  and transfer to 50 mL vol. flask. Rinse beaker with 4 addnl small portions  $\text{CHCl}_3$ , and transfer to vol. flask. Dil. to vol. with  $\text{CHCl}_3$  (disregard turbidity and slight color in soln).

Transfer 25 mL  $\text{CHCl}_3$  soln, measured in graduate or fast-flow pipet, to 125 mL separator. Proceed as in 29.120, beginning, "Add 25 mL bromophenol blue soln, (a), . . ."

Perform detns along with prepn of std curve, using 0 std as ref. when detg sample A. Det. amt of 2-heptadecyl glyoxalidine in aliquot from std curve.

Glyodin (2-heptadecyl glyoxalidine acetate) = 2-heptadecyl glyoxalidine  $\times$  1.195.

### Hexachlorobenzene (HCB) and Mirex in Fatty Products (27)—Official Final Action

### 29.123 *Reagents*

(a) *Solvents*.—Hexane, methylene chloride, acetonitrile, and pet ether. See 29.002.

(b) *Florisil*.—60–100 mesh PR grade. (1) *Unactivated*, for partition chromatography.—Use as received from manufacturer. (2) *Activated*.—See 29.002(i).

(c) *Eluant mixture*.—For Florisil column cleanup. Dil. 200 mL  $\text{CH}_2\text{Cl}_2$  with hexane. Let reach room temp. and adjust to 1 L with hexane.

### 29.124 *Apparatus*

(a) *Gas chromatograph*.—With electron capture detector. See 29.008(a) and (c).

(b) *Column*.—1.85 m  $\times$  4 (id) mm glass column with 80–100 mesh Chromosorb W (HP) support, N flow 120 mL/min, and injection temp. 220°. For HCB analysis, use 15% OV-210 substrate; for Mirex, 3% OV-101. For HCB, use column temp. 180°, detector, 200°; for Mirex, use column temp. 210°, detector 220°. Operate  $^3\text{H}$  electron capture detector at dc voltage which produces half scale deflection for 0.5 ng HCB or Mirex when electrometer sensitivity is  $1 \times 10^{-9}$  amp. Or, operate  $^{63}\text{Ni}$  detector to produce stable, reproducible, linear response and adjust amt

of injected sample, 29.018, to accomodate difference in instrument sensitivity.

(c) *Chromatographic tubes*.—(1) *Plain*.—250  $\times$  22 (id) mm. (2) *With stopcocks*.—See 29.005(b).

(d) *Kuderna-Danish concentrators*.—See 29.005(e).

(e) *Micro-Vigreux Column*.—See 29.005(h). Use for concn to vols  $< 5$  mL.

### 29.125 *Extraction of Fat*

Ext  $\geq 3$  g fat as in 29.012. For products reported on fat basis, use 3 g fat. For products reported on as-is basis, record wt, W, of fat extd. Corresponding wt sample analyzed = (wt fat taken for cleanup/W)  $\times$  wt original sample.

### 29.126 *Cleanup*

(Caution: See 51.043 and 51.073.)

Weigh 3 g fat into 250 mL beaker, add 20 g unactivated Florisil, and stir with spatula or glass rod until free-flowing powder is obtained. Place glass wool plug in bottom of plain chromatgc tube and add 3 g unactivated Florisil. Completely transfer fat-Florisil mixt. to tube. Settle column by repeatedly tapping tube. Place glass wool plug on top of Florisil. Place 1 L separator under column as receiver. Elute with 150 mL  $\text{CH}_3\text{CN}$  by gravity.

When elution is complete, add exactly 100 mL pet ether to separator, and shake vigorously 1–2 min. Add 10 mL satd NaCl soln and 500–600 mL  $\text{H}_2\text{O}$ , and shake vigorously 1 min. Let sep. and discard aq. (lower) layer. Wash pet ether with two 100 mL portions  $\text{H}_2\text{O}$ . Discard washings, transfer pet ether to 100 mL g-s graduate, and record vol., P. Calc.

Wt sample in eluate = (wt sample taken for cleanup  $\times$  P/100, where 100 = mL pet ether added).

Complete cleanup on column of activated Florisil, 29.015, using amt Florisil detd from lauric acid test, 29.002(i). Sample ext must be dry and free from polar solvs when placed on column. Elute at ca 5 mL/min with 200 mL eluant mixt., (c), and conc. Det HCB and Mirex as in 29.018, using column, 29.124(b).

### ★ Malathion ★

(S-[1,2-bis(Ethoxycarbonyl)ethyl]  
O,O-Dimethyl Phosphorodithioate)

### 29.127 *Multiple Residue Methods*

See 29.001–29.028, 29.044–29.049, and 29.050–29.054.

### 29.128 ★ *Colorimetric Method (28)—Official First Action* ★

(Applicable to residues on surface of fruits and vegetables)

Malathion is extd with either  $\text{CCl}_4$  or mixt. of  $\text{CCl}_4$  and isopropanol and decomposed by alkali in  $\text{CCl}_4$ -alcohol soln into Na O,O-dimethyl phosphorodithioate, Na fumarate, and alcohol. Na O,O-dimethyl phosphorodithioate is converted to cupric salt which is sol. in  $\text{CCl}_4$  with formation of intense yellow color. Color intensity is proportional to concn of O,O-dimethyl phosphorodithioic acid and is measured photometrically at 418 nm. See 29.116–29.120, 12th ed.

### Maleic Hydrazide (29)—Official Final Action

(Applicable to whole, dehydrated mashed, and frozen french fried potatoes, and potato chips; whole cranberries, onions, and peaches; and tobacco dust)

### 29.129 *Principle*

Sample is boiled in alk. soln to drive off volatile basic interferences. Distn with Zn with N sweep expels hydrazine

★ Surplus method—see inside front cover.

liberated from maleic hydrazide. Hydrazine is reacted in acid soln with *p*-dimethylaminobenzaldehyde to form yellow compd.

**29.130****Apparatus**

(a) *Distillation apparatus*.—See Fig. 29:08. Flask is 300 mL capacity, flat-bottom, double thickness, with thermometer well. Thermometer is 90–220° (Tinius Olsen No. 718636 "Yellow Bak," or equiv. in temp. range and length; available on special order from Accuracy Scientific Instrument Co., 335 E Chew Ave, Philadelphia, PA 19120). Use 5" wire gauze with 4" diam. asbestos center. Centrf. tube receiver (50 mL) is graduated in 1 mL divisions.

(b) *Spectrophotometer*.—Beckman Model DU, or equiv.

**29.131****Reagents**

(a) *p*-Dimethylaminobenzaldehyde soln.—Dissolve 2 g in 100 mL 1*N* H<sub>2</sub>SO<sub>4</sub>. Soln is stable.

(b) *Zn granules*.—"10 mesh."

(c) *Maleic hydrazide std soln*.—10 µg/mL. Dissolve 0.0100 g maleic hydrazide in 100 mL 0.1*N* NaOH and dil. to 1 L. Soln is stable.

**29.132****Preparation of Sample**

Grind sample to soup-like consistency in high-speed blender, adding measured wt of H<sub>2</sub>O if necessary. Prepd samples may be frozen for storage.

**29.133****Determination**

Transfer 2 g ground sample to 300 mL distn flask. Dry socket neck joint, and add 50 g NaOH pellets, 1 mL *refined vegetable oil*, as anti-foaming agent, and 40 mL H<sub>2</sub>O. Add 1 mL high bp oil to thermometer well and insert thermometer. Heat flask on high-temp. hot plate and swirl ca every 20 sec until pellets dissolve and gentle boiling begins. When temp. reads 160°, remove flask and let cool 5 min. Wipe socket joint clean and dry; add 0.5 g *ferrous chloride* and 5 mL (equiv. to ca 5 g) Zn.

Quickly grease socket joint with light film of high-vac. silicone grease and attach flask to app. (Fig. 29:08). Center flask firmly on asbestos pad. Place 4 mL *p*-dimethylaminobenzaldehyde soln in 50 mL centrf. tube (ice-cooled) and immerse condenser tip. Adjust N flow (*dry N*) to 3 bubbles/sec in receiver. With rapid flow of condenser H<sub>2</sub>O, heat flask with Bunsen burner, centering tip of outer cone of flame on asbestos pad. When boiling begins, adjust distance of burner so foaming contents fill ca 2/3 of flask. Distil until temp. reads 173°, *slowly* add H<sub>2</sub>O from reservoir until temp. drops to 168°, turn off H<sub>2</sub>O, and distil to 173°. Continue H<sub>2</sub>O addn and distn at these temps until receiver contains ca 40 mL. Remove receiver. (If during distn receiver soln becomes turbid or ppt appears, add 2 drops H<sub>2</sub>SO<sub>4</sub> and shake.)

Record vol. of distillate and det. *A* at 430, 460, and 490 nm, using 1 cm cells and 4 mL *p*-dimethylaminobenzaldehyde soln dild to 40 mL as ref.

After distn, remove hot distg flask from app. with heat-resistant gloves, remove thermometer, and seal well with small cork. Rinse N-H<sub>2</sub>O inlet tube free of caustic with HCl from plastic squeeze bottle followed by H<sub>2</sub>O. Then (with gloves and safety glasses) pour molten contents of distg flask into Fe can in sink to trap Zn granules. Rinse flask 3 times with H<sub>2</sub>O and 2 times with HCl to remove encrusted caustic and Zn granules. Fill flask with HCl (1+9) to remain until next use. Rinse 3 times with H<sub>2</sub>O before reuse. (Careful removal of *all* Zn granules with HCl is essential because residual Zn would cause premature destruction of maleic hydrazide in precook of next sample. Because of

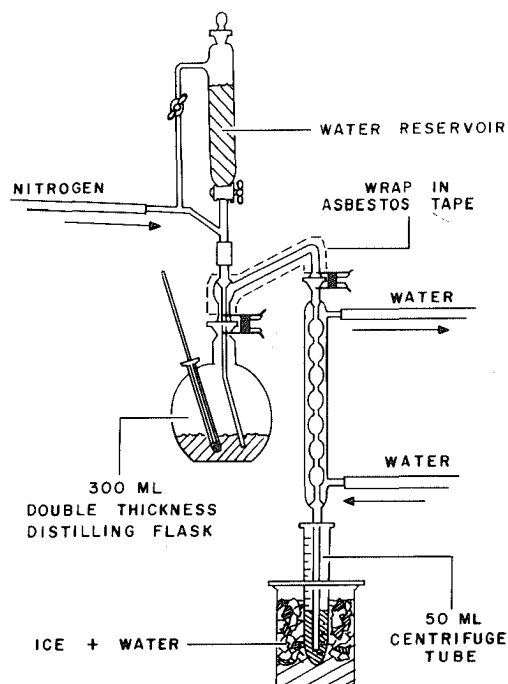

FIG. 29:08—Distillation apparatus for maleic hydrazide determination

corrosion by the caustic soln, flasks may last for only ca 30 detns.)

**29.134****Preparation of Standard Curve**

To clean 300 mL distn flasks, add 50 g NaOH pellets, 40 mL H<sub>2</sub>O, and std soln equiv. to 0, 5, 10, 20, 30, 50, 100, 150, and 200 µg maleic hydrazide. Precook, distil, and measure *A* as in 29.133. Det.  $\Delta A$  for each std as follows:

$$\Delta A = [A_{460} - ((A_{430} + A_{490})/2)] \times \text{mL color soln}/40.$$

Plot  $\Delta A$  of each std against µg maleic hydrazide to obtain std curve. If desired, derive simple factor from curve slope, *K*, converting  $\Delta A$  to µg maleic hydrazide; thus, µg maleic hydrazide =  $\Delta A \times K$ .

**29.135****Calculations**

Multiply  $\Delta A$  of sample by *K* to derive µg maleic hydrazide; ppm = µg/sample wt (g).

**Methoxychlor (2,2-Bis(*p*-Methoxyphenyl)-1,1,1-Trichloroethane)**

**29.136****Multiple Residue Methods**

See 29.001–29.028.

**29.137**

★ **Colorimetric Method (30)** ★  
**Official Final Action**

(Applicable to fruits and vegetables)

Pet ether soln of ext of sample is extd with CH<sub>3</sub>CN to sep. methoxychlor from fats and plant waxes. Methoxychlor in concd ext is dehalogenated and converted by alk. hydrolysis to dehydrochloride, which is sepd by pet ether extn and reacted with 85% H<sub>2</sub>SO<sub>4</sub> to produce red soln. See 24.149–24.152, 10th ed. (Caution: See 51.011, 51.039, and 51.073.)

★ Surplus method—see inside front cover.

**Mirex****29.138 Multiple Residue Methods**

See 29.001–29.018.

**29.139 HCB and Mirex**

See 29.123–29.126.

**Monofluoroacetic Acid**  
(Sodium Salt, "1080") (31)

**Qualitative Test—Official Final Action**

(Monochloroacetic acid also responds to this test. Confirm presence of org. F by 29.142–29.148.)

**29.140 Reagents**

(a) *Decolorizing carbon*.—See 16.027(b).

(b) *Thiosalicylic acid soln.*—Dissolve 300 mg thiosalicylic acid (Eastman P2805 is suitable) in mixt. of 2 mL 1*N* NaOH and 18 mL H<sub>2</sub>O.

(c) *Potassium ferricyanide soln.*—Dissolve 1 g K<sub>3</sub>Fe(CN)<sub>6</sub> in H<sub>2</sub>O and dil. to 50 mL with H<sub>2</sub>O.

**29.141 Test**

Prep. sample and ext as in 29.145–29.146. If convenient, ext large enough sample to obtain 2–10 mg 1080. With very low levels of 1080, e.g., 1–5 ppm, ext large enough sample to obtain ≥0.5 mg 1080.

Sep. ether ext from any aq. sludge which may have been carried over in extn, add ca 5 g anhyd. Na<sub>2</sub>SO<sub>4</sub> and 0.5 g decolorizing C/100 mL ether, and shake vigorously. Let stand ca 15 min at room temp. with occasional shaking, and decant thru fluted paper into separator. Add ca 25 mL H<sub>2</sub>O and enough NaOH soln (ca 1*N*) to make aq. layer alk. after vigorous shaking (outside test paper). Drain aq. layer into 125 mL erlenmeyer and aerate to remove dissolved ether. Using pH test paper and ca 1*N* solns of H<sub>2</sub>SO<sub>4</sub> and NaOH, adjust to pH 4–6. Add 0.5 g C and place on steam bath for 15 min.

Cool under tap and filter thru fluted paper into ca 25 × 150 mm test tube. Add 1 mL thiosalicylic acid soln and 2 drops NaOH (1+1), and mix. Conc. soln to small vol. by placing on steam bath under gentle air current. Completely dry residue in oven at 130° or, if time is not factor, in 100° oven. (When convenient, overnight drying is satisfactory, with or without prior concn of soln.)

Dissolve *thoroly* dry residue in 2–3 mL H<sub>2</sub>O, add 1 mL K<sub>3</sub>Fe(CN)<sub>6</sub> soln, and mix. Red ppt, which forms at once when ≥1 mg 1080 is present, or upon standing when only fraction of mg is present, is pos. test for 1080.

Employ chromatgc instead of C purification in following cases:

- (1) With pineapple juice when <2 mg 1080 can be extd.
- (2) With grape juice even when ≥2 mg of 1080 can be conveniently extd.
- (3) With any food or material when 1080 is strongly suspected and neg. test is obtained using C purification technic.

For chromatgc purification, follow 29.147 for sepg 1080 from other acids. Discard forerun, which may contain HOAc and other extraneous materials. Collect fraction large enough to contain all the 1080 as detd by preliminary detn. Ext fluoroacetic acid from eluate with 25 mL H<sub>2</sub>O and enough alkali to cause aq. layer to retain alky after vigorous shaking (outside test paper). Drain org. layer and discard. Drain aq. layer into 125 mL erlenmeyer and aerate to remove CHCl<sub>3</sub>. Pour soln into test tube and continue as above, beginning "Add 1 mL thiosalicylic acid soln ..."

**Quantitative Method—Official Final Action****29.142 Principle**

After suitable sample prepn, acid is extd with ether and sepd from inorg. fluorides (partially ether-sol.) by partition chromatgy on silicic acid, using 0.5*N* H<sub>2</sub>SO<sub>4</sub> as immobile solv. and CHCl<sub>3</sub> contg 10% *tert*-amyl alcohol or *n*-BuOH as mobile solv. Mono-fluoroacetic acid in eluate is converted to its Na salt, and quantity is detd by micro F detn, 25.053(a), 25.054, and 25.055.

**29.143 Apparatus**

(a) *Chromatographic tubes*.—18 mm od × 250 mm long, prepd from Pyrex tubing.

(b) *Pressure source*.—Compressed air or cylinder of N or CO<sub>2</sub>, and means of keeping pressure const, such as Hg column or diaphragm-type pressure regulator.

(c) *Mixer*.—High-speed blender.

**29.144 Reagents**

(a) *Silicic acid*.—Mallinckrodt analytical reagent grade pptd powder, or equiv.

(b) *Mobile solvent*.—Add 100 mL *tert*-amyl alcohol or *n*-BuOH to 900 mL CHCl<sub>3</sub>, and mix.

(c) *Phosphotungstic acid soln.*—Dissolve 20 g in H<sub>2</sub>O and dil. to 100 mL.

**29.145 Preparation of Sample**

This will vary with type of material. Dissolve sugars in H<sub>2</sub>O, acidify with H<sub>2</sub>SO<sub>4</sub>, and ext directly. Following methods for different type materials will be suggestive. Simple H<sub>2</sub>O wash may be adequate to prove contamination of certain foods.

(a) *Sugar*.—Dissolve 100 g sample in enough H<sub>2</sub>O to give ca 350 mL.

(b) *Flour*.—Place 100 g sample in mixer, add 400 mL H<sub>2</sub>O and 5 g *pancreatin*, and comminute ca 2 min. Adjust to pH 7–8, using *satd* Na<sub>3</sub>PO<sub>4</sub>·12H<sub>2</sub>O soln and suitable indicator paper. Transfer comminuted material to tared 1 L erlenmeyer, washing mixer with three 25 mL portions H<sub>2</sub>O. Incubate mixt. ≥3 hr at 35–40°. Add 5 mL H<sub>2</sub>SO<sub>4</sub> (1+1) and swirl. Add 20 mL phosphotungstic acid soln and swirl again. Dil. to 750 g with H<sub>2</sub>O, stopper, and shake vigorously ca 2 min. Filter thru fluted paper or with suction thru buchner (16 cm size is convenient). Or, more quickly, centrf. and decant supernate. Use ≥375 g aliquot of filtrate. (Since sp gr of filtrate is very close to 1, measuring out aliquot in graduate is satisfactory.)

(c) *Wheat*.—Finely grind sample in suitable mill, such as Wiley mill. Proceed as in (b).

(d) *Corn meal*.—Proceed as in (b), except omit pancreatic digestion.

(e) *Corn*.—Grind sample and proceed as in (d).

(f) *Peanuts*.—Grind sample finely (like peanut butter) and proceed as in (d), except use 100 mL phosphotungstic acid soln. If necessary, refilter thru folded paper to remove oil.

(g) *Cheese*.—Proceed as in (d), except use 40 mL phosphotungstic acid soln.

(h) *Other foods such as chili peppers, cacao beans, etc.*—Treat in manner similar to one of preceding foods.

(i) *Biological tissue*.—If material is tough or fibrous, grind it twice thru food chopper. (Soft tissues, e.g., brain and liver, need not be ground.) Place 100 g ground tissue in 800 mL beaker, add ca 300 mL H<sub>2</sub>O, cover with watch glass, and boil gently ca 30 min. Transfer material to mixer, rinsing beaker with two 25 mL portions H<sub>2</sub>O, and comminute *thoroly* (ca 2 min). Transfer comminuted material to tared 1 L erlenmeyer, rinsing mixer with two 25 mL portions H<sub>2</sub>O. Add 5 mL H<sub>2</sub>SO<sub>4</sub> (1+1) and mix.

Add enough phosphotungstic acid soln (50–75 mL) to ppt all proteins, then H<sub>2</sub>O to make 600 g. Shake vigorously ca 2 min, and filter thru fluted paper or with suction thru buchner. If material does not filter rapidly, return mixt. to flask, add ca 10 mL addnl phosphotungstic acid soln, shake vigorously, and refilter.

**Alternative method.**—Place 100 g ground tissue in mixer, add 300 mL H<sub>2</sub>O and 15 g pancreatin, and comminute thoroly (ca 2 min). Adjust to ca pH 8 with *satd* Na<sub>3</sub>PO<sub>4</sub>·12H<sub>2</sub>O soln, using suitable indicator paper. Transfer comminuted material from mixer to tared erlenmeyer, washing mixer with two 25 mL portions H<sub>2</sub>O and incubate ca 3 hr at 35–40°. Ppt proteins and make to wt as directed previously.

**29.146****Extraction**

Transfer soln (of sugar) or wt-aliquot of protein-free filtrate (of protein-contg materials) to 200 mL continuous extractor, Fig. 16:02. (Tube is 115–120 cm long and 33–34 mm od, side arm, attached ca 63 cm from bottom, is 15–16 mm od; and inner tube is 12–13 mm od flared at top to ca 25 mm diam.; 1.5 L extractors of this type have been used successfully. Extra coarse fritted filter tip on bottom end of inner tube aids in getting smaller droplets of extg solv.) For each 50 g soln, add 1 mL H<sub>2</sub>SO<sub>4</sub> (1+1). Ext with ether until all fluoroacetic acid has been extd (dtd by preliminary experiment; usually 3–4 hr with 400 mL extractor). Transfer ether ext to separator of appropriate size.

To extn flask add ca 20 mL H<sub>2</sub>O, 2 drops phthln, and enough 1.0*N* NaOH from buret to give strong alk. color of indicator after swirling. Pour rinse soln into separator and add addnl alkali until alk. color of indicator persists in aq. phase after vigorous shaking. Record vol. alkali required. Drain aq. layer into 100 mL beaker and wash ether with two 10 mL portions H<sub>2</sub>O, rinsing extn flask each time with the H<sub>2</sub>O before pouring it into separator. Add washings to beaker. Carefully adjust alky of ext just to alk. color of phthln with 0.1*N* H<sub>2</sub>SO<sub>4</sub> and NaOH solns. Evap. neutzd ext to dryness on steam bath (current of air hastens evapn). If during evapn alk. color of indicator should disappear, add just enough 0.1*N* NaOH to give alk. color again. Do not continue heating after residue is apparently dry. Slightly moist residue is permissible.

**29.147****Chromatography**

To 5 g silicic acid, (a), in mortar, add max. amt of 0.5*N* H<sub>2</sub>SO<sub>4</sub> that it will hold without becoming sticky (50–80% of its wt). Mix well with pestle; then add ca 35 mL of the mobile solv. and work up into smooth slurry. (If SiO<sub>2</sub> agglomerates in solv., too much H<sub>2</sub>SO<sub>4</sub> was used.) Place small cotton plug in bottom of chromatgc tube and pour in slurry, tilting tube slightly to avoid air bubbles. Let silicic acid pack down under 2–10 lb (14–69 kPa) pressure applied thru gas pressure regulator. When excess solv. has drained thru (column firm and viscous enough to resist pouring when tipped), column is ready for use. In prep column take care to avoid cracking or drying out of the gel caused by leaving pressure on after column packs down and all solv. sinks into gel.

To dry or slightly moist residue in 100 mL beaker add enough H<sub>2</sub>SO<sub>4</sub> (1+1) (ca 18*N*), usually 0.5–1.0 mL, to give excess of ca 0.25 mL over vol. necessary to convert all salts to free acid, as calcd from amt of 1*N* NaOH required to neutze acid extd by the ether. Wet salts *thoroly* with the acid, using small, narrow blade spatula (steel or Monel metal) to loosen salts from glass, and using flat-end glass rod to break up solid particles and mix resulting slurry. Add 5–10 g anhyd. granular Na<sub>2</sub>SO<sub>4</sub> to take up excess liq. Stir well with tamping rod, breaking up any lumps.

Add 10 mL mobile solv., (b), stir thoroly, and decant solv. carefully onto column.

Catch eluate in graduate. Apply pressure until all solv. sinks into gel; then release pressure. Add 5 mL mobile solv. to beaker and again stir thoroly. Carefully decant solv. onto column and, with aid of narrow-blade spatula, transfer bulk of material in beaker, mostly Na<sub>2</sub>SO<sub>4</sub>, to column. Renew pressure. When solv. passes ca halfway thru Na<sub>2</sub>SO<sub>4</sub>, release pressure. Rinse out beaker with addnl 5 mL solv. and transfer to column. After this washing sinks ca halfway into Na<sub>2</sub>SO<sub>4</sub>, fill tube with mobile solv. and complete collection, under pressure, of enough eluate to obtain all monofluoroacetic acid, as dtd by test run on silicic acid used (ca 50 mL). Collect dropwise; 3–4 mL/min is convenient rate.

Transfer eluate to 125 mL separator; add ca 20 mL H<sub>2</sub>O and enough 1.0*N* NaOH to give alk. color of phthln (phthln is present in eluate and no further addn is required) in aq. phase, after vigorous shaking. Drain aq. layer into 125 mL erlenmeyer and return solv. layer to separator. Wash solv. with two 10 mL portions H<sub>2</sub>O and add washings to erlenmeyer. Aerate soln with current of air to remove traces of CHCl<sub>3</sub>. (If excess CHCl<sub>3</sub> is not removed, excessive Cl may complicate F distn in next step.)

**29.148****Determination**

Transfer aq. ext to Pt dish with little H<sub>2</sub>O and mix with ca 20 mL lime suspension, 25.049(a), evap. to *dryness*, and ash 15–20 min at 600°. (Little C in ash will not interfere in detn.) Proceed as in 25.053(a), beginning "When clean ash is obtained, . . ." and 25.054–25.055 (100 mL Nessler tubes are preferable). Convert F results to fluoroacetic acid (× 4.11) or to Na monofluoroacetate (1080) (× 5.26) as desired, and correct for aliquot taken, if any, in extn. Ignore vol. occupied by insol. solids.

**Naphthaleneacetic Acid (NAA) (32)****Official Final Action**

(Applicable to apples and potatoes)

**29.149****Apparatus**

(a) *Spectrophotometer*.—Cary 15 (current Model Cary 219, Varian Instruments), or equiv., with 5 cm cells.

(b) *Chromatographic tube*.—Glass, 22 mm id × 200 mm.

(c) *Food chopper*.—Hobart No. 84141 (Hobart Manufacturing Co., 711 Pennsylvania Ave, Troy, OH 45373), or equiv.

(d) *Blender cups*.—Stainless steel, 1 L capacity, with air-tight screw cover (Scientific Products, Inc. No. S8390) for high-speed blender.

**29.150****Reagents**

(a) *Sodium phosphate soln*.—0.5*M*. 134 g Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O or 70.5 g anhyd. salt/L.

(b) *Permanganate soln*.—0.02*M*. 31.6 g KMnO<sub>4</sub>/L.

(c) *Florisil*.—60–100 mesh PR grade activated at 675° (1250°F) (Floridin Co.); use as received.

(d) *Naphthyleneacetic acid (NAA) soln*.—0.1 mg α-NAA/mL CHCl<sub>3</sub>.

**29.151****Extraction**

Chop sample in food chopper and transfer 200 g to blender cup. Add 20 mL 1*N* H<sub>2</sub>SO<sub>4</sub> and 400 mL CHCl<sub>3</sub>, screw top on blender, and blend 2 min at low speed. Pour mixt. into 500 mL centrf. bottle and centrf. 10 min at 1600 rpm. Take 200 mL aliquot from CHCl<sub>3</sub> layer.

## 29.152

## Cleanup

(a) *Apples*.—Place glass wool plug into chromatgc tube, add 10 cm Florisil, and top Florisil with glass wool plug. Transfer 200 mL  $\text{CHCl}_3$  ext to column with min. amt  $\text{CHCl}_3$ . Rinse inside of tube twice with ca 5 mL  $\text{CHCl}_3$ . Elute column, in order, with 100 mL portions of  $\text{CH}_3\text{CN}$ , ether,  $\text{NH}_3$ -satd  $\text{CHCl}_3$ , and  $\text{CHCl}_3$  and discard eluates. Using 500 mL separator as receiver, elute NAA with 100 mL 1% HOAc in  $\text{CHCl}_3$  followed by 100 mL  $\text{CHCl}_3$ . Discard column, add 50 mL 1*N*  $\text{H}_2\text{SO}_4$  to separator, and shake vigorously. Transfer  $\text{CHCl}_3$  layer to 250 mL separator contg 50 mL  $\text{H}_2\text{O}$  and shake vigorously. Transfer  $\text{CHCl}_3$  layer to 250 mL separator contg exactly 50 mL 0.5*M*  $\text{Na}_2\text{HPO}_4$ , shake vigorously, and discard  $\text{CHCl}_3$  layer.

(b) *Potatoes*.—Proceed as in (a). Add 2 mL 85%  $\text{H}_3\text{PO}_4$  and 2 mL 0.02*M*  $\text{KMnO}_4$  to separator contg  $\text{Na}_2\text{HPO}_4$  phase, mix, and let stand exactly 5 min. Ext NAA with two 25 mL portions  $\text{CHCl}_3$ , transfer  $\text{CHCl}_3$  exts to 125 mL separator contg exactly 50 mL 0.5*M*  $\text{Na}_2\text{HPO}_4$ , shake vigorously, and discard  $\text{CHCl}_3$  layer.

## 29.153

## Determination

(a) *Apples*.—Transfer 1 mL NAA std soln to 125 mL separator, add exactly 50 mL 0.5*M*  $\text{Na}_2\text{HPO}_4$  and 50 mL  $\text{CHCl}_3$ , and shake vigorously. Let layers sep. and discard  $\text{CHCl}_3$  layer. Obtain UV spectra (230–330 nm) of cleaned up apple ext and NAA std ext, using 5 cm cells, against 0.5*M*  $\text{Na}_2\text{HPO}_4$ . Use peak at 283 nm to compare apple ext and NAA std ext, correcting for baseline *A*, and calc. ppm NAA present.

(b) *Potatoes*.—Transfer 1 mL NAA std soln to 125 mL separator, add 50 mL 0.5*M*  $\text{Na}_2\text{HPO}_4$  and 50 mL  $\text{CHCl}_3$ , and shake vigorously. Let layers sep. and discard  $\text{CHCl}_3$  layer. Add 2 mL 85%  $\text{H}_3\text{PO}_4$  and 2 mL 0.02*M*  $\text{KMnO}_4$  to separator, mix, and let stand exactly 5 min. Ext NAA with two 25 mL portions  $\text{CHCl}_3$ , transfer  $\text{CHCl}_3$  exts to 125 mL separator contg exactly 50 mL 0.5*M*  $\text{Na}_2\text{HPO}_4$ , shake vigorously, let layers sep., and discard  $\text{CHCl}_3$  layer. Obtain UV spectrum and calc. ppm NAA as in (a). (If there is excessive interference in sample spectra, repeat 5 min oxidn for both sample and std, beginning with "Add 2 mL 85%  $\text{H}_3\text{PO}_4$  . . .")

## Nicotine (33)—Official Final Action

(Applicable to apples, cabbage, and spinach)

## 29.154

## Reagents

(a) *Dilute hydrochloric acid*.—Approx. 0.05*N*. Dil. 4.1 mL HCl to 1 L.

(b) *Nicotine std solns*.—(1) *Stock soln*.—1 mg/mL. Dil. 100 mg nicotine (Eastman Kodak Co. No. 1242, or equiv.) to 100 mL in vol. flask with ca 0.05*N* HCl. (*Caution*: nicotine is very toxic.) (2) *Working soln*.—0.01 mg/mL. Pipet 1 mL stock soln into 100 mL vol. flask and dil. to vol. with ca 0.05*N* HCl.

(c) *Stripping soln*.—Dil. 20 mL  $\text{NH}_4\text{OH}$  to 2 L in vol. flask. Prep. at time of use.

## Leafy Crops

## 29.155

## Preparation of Sample

(*Caution*: See 51.040, 51.045, and 51.056.)

Weigh 500 g chopped sample (spinach, cabbage) into clean, dry jar (3–5 gal.; 11–20 L). Add 800 mL benzene, 200 mL  $\text{CHCl}_3$ , and 10 mL  $\text{NH}_4\text{OH}$ . Close, tumble or roll ca 10 min, and drain soln as completely as possible into 1 L beaker. Filter thru folded 38.5 cm paper into flask and proceed immediately with detn.

## 29.156

## Determination

Place 400 mL filtered soln in 500 mL separator. Add 25 mL ca 0.05*N* HCl and 2 mL HCl, and shake vigorously. Let phases sep. (ca 5 min) and drain lower layer into 250 mL separator. Swirl large separator, let stand ca 2 min, and drain any addnl ext into 250 mL separator. Repeat several times. Then ext soln with 25, 25, 15, and 10 mL portions ca 0.05*N* HCl, repeating swirling as above. Drain all acid exts into 250 mL separator. Make exts just alk. to litmus with 10% NaOH soln. Ext with two 50 mL and four 25 mL portions  $\text{CHCl}_3$ , combining exts in 250 mL separator.

Add 2 mL HCl to exts and make sure soln is acid to litmus. Ext with 25, 25, 20, 10, and 5 mL portions ca 0.05*N* HCl, combining all exts in short-stem 125 mL separator. Wash exts with 15 mL pet ether. Drain aq. layer into second 125 mL separator and wash pet ether with 5 mL ca 0.05*N* HCl, adding wash to combined acid soln. Ext soln with another 15 mL pet ether, drain aq. layer into 100 mL vol. flask, and wash pet ether with 5 mL ca 0.05*N* HCl. Drain acid into vol. flask and dil. to vol. with ca 0.05*N* HCl. Mix, pour portion into 50 mL beaker, and let stand 10–15 min. Det *A* at 236, 259, and 282 nm with ca 0.05*N* HCl as ref. Confirm presence of nicotine by reading at 2 nm intervals and plot absorption curve, or use recording spectrophtr. Det. *A* of std nicotine soln against ca 0.05*N* HCl as ref.

## Waxy Crops

## 29.157

## Preparation of Sample

Weigh 2–2.5 kg apples into clean, dry, jar (3–5 gal.; 11–20 L). Add 1 L stripping soln, tumble or roll ca 10 min, and drain carefully into 1 L beaker. Filter thru folded 38.5 cm paper into flask and proceed immediately with detn.

## 29.158

## Determination

Place 400 mL filtered soln in 500 mL separator. Add 50 mL  $\text{CHCl}_3$ , invert separator back and forth gently ca 2 min, and let phases sep. Drain clear portion of ext into 250 mL separator. (With fruits, emulsions may form which are very hard to break. Break emulsions by drawing  $\text{CHCl}_3$  layer into dry 125 mL separator and shaking vigorously. Separator must be dry.) Let phases sep. and drain clear portion into the 250 mL separator. Add 35 mL  $\text{CHCl}_3$  to the 125 mL separator, shake gently, and drain into the 500 mL separator. Ext as above and combine clear ext in the 250 mL separator. Ext with 35, 35, and 10 mL  $\text{CHCl}_3$ , combining exts in the 250 mL separator. Add  $\geq 1$  mL HCl to exts until definitely acid to litmus. Then ext with three 15 mL portions ca 0.05*N* HCl, combining acid exts in a 125 mL separator. Wash the 250 mL separator with 10 mL ca 0.05*N* HCl after each extn and add to 125 mL separator used to break emulsions. Shake, but do not attempt to break any emulsions in this separator. Combine all acid exts in 125 mL separator and shake with 15 mL pet ether. Let stand ca 5 min and drain aq. layer into another 125 mL separator. Wash pet ether with 5 mL ca 0.05*N* HCl (do not shake vigorously) and add washings to separator. Repeat washing with 15 mL pet ether and drain aq. ext into 100 mL vol. flask. Wash pet ether as before, add washings to flask, and let stand 10–15 min. Dil. to vol. with ca 0.05*N* HCl and det. *A* at 236, 259, and 282 nm, against ca 0.05*N* HCl as ref. Confirm presence of nicotine as in 29.156.

Take *A* of std soln as:

$$A_{\text{std}} = A'_{259} - 0.5(A'_{236} + A'_{282})$$

and *A* of sample soln as:

$$A_{\text{samp.}} = A_{259} - 0.5(A_{236} + A_{282})$$

Then:

$$\text{mg Nicotine} = (A_{\text{samp.}}/A_{\text{std}}) \times 2.5.$$

## Parathion

29.159 *Multiple Residue Methods*

See 29.001–29.024, 29.039–29.043, 29.044–29.049, and 29.050–29.054.

29.160 ★ *Colorimetric Method (34)* ★  
*Official Final Action*

Parathion is extd with benzene or isopropanol-benzene and the strip soln is clarified. Parathion is brought into aq. soln and simultaneously reduced to its amine with Zn-HCl. The amine is diazotized and coupled with N-(1-naphthyl)ethylenediamine to form colored compd. See 29.139–29.144, 11th ed.

*Piperonyl Butoxide (35)*  
*Official Final Action*

(Applicable to Alaska peas, barley, hulled rice, oats, pinto beans, and wheat)

29.161 *Principle*

Strong  $\text{H}_2\text{SO}_4$  liberates  $\text{HCHO}$ , which is detd colorimetrically with chromotropic acid.

29.162 *Reagents*

(a) *Chromotropic acid reagent*.—Dissolve 100 mg Na 1,8-dihydroxynaphthalene-3,6-disulfonate/mL of  $\text{H}_2\text{O}$ , filter, and keep in dark. Prep. daily. (1 mL required for each detn.)

(b) *Dilute sulfuric acid*.—Carefully mix 5 vols  $\text{H}_2\text{SO}_4$  with 3 vols  $\text{H}_2\text{O}$ . Cool to room temp. and store in tight g-s container.

(c) *Methanolic potassium hydroxide*.—Dissolve 1.4 g KOH in 5 mL  $\text{H}_2\text{O}$  and add 95 mL MeOH (HCHO-free).

(d) *Methanol*.—If necessary, purify as follows: Reflux 1 L MeOH 1 hr with ca 10 g powd Al and ca 10 g NaOH and distil ca 800–900 mL.

(e) *Hexane*.—Redistd.

(f) *Chloroform*.—Reagent or redistd (for wheat extrn).

(g) *Piperonyl butoxide std solns*.—(1) *Stock soln*.—1 mg/mL. Dissolve 0.1000 g in 100 mL benzene. (2) *Intermediate soln*.—100  $\mu\text{g/mL}$ . Dil. 10 mL stock soln to 100 mL with benzene. (3) *Working soln*.—20  $\mu\text{g/mL}$ . Dil. 20 mL intermediate soln to 100 mL with benzene.

29.163 *Preparation of Standard Curve*

Add 0, 20, 40, 60, 80, and 100  $\mu\text{g}$  piperonyl butoxide, resp., to each of 6 g-s test tubes (15 × 150 mm) (25–50 mL g-s centrf. tubes are also satisfactory) and evap. on steam bath with small air jet. Evap. last 1–2 mL benzene without heat.

Into each tube pipet both 1 mL chromotropic acid reagent and 5 mL dil.  $\text{H}_2\text{SO}_4$ . (b). Stopper loosely and place tubes in beaker of boiling  $\text{H}_2\text{O}$  45 min, remove, and cool in beaker of cold  $\text{H}_2\text{O}$ . When cool, pipet 5 mL  $\text{H}_2\text{O}$  into each test tube, mix well, and read  $A$  in spectrophtr at 575 nm against reagent blank prepd similarly. Plot  $\mu\text{g}$  piperonyl butoxide against  $A$ .

29.164 *Determination*

Ext sample as in 29.098(c), using  $\text{CHCl}_3$ . With current of air, evap. 25 mL (or suitable size aliquot) ext in small beaker just to dryness. Add 5 mL methanolic KOH. Warm gently just enough to melt wax (do not boil). Let stand 30 min, swirling vigorously at ca 10 min intervals. Transfer to small separator, rinse beaker with two 5 mL portions  $\text{H}_2\text{O}$ , and add to separator. Add 15 mL hexane to separator, shake vigorously 1 min, and let sep. Drain aq. layer and discard. Quant. transfer hexane layer to g-s test

tube or centrf. tube and evap. to dryness with air jet. Small amt of heat may be used, but evap. last 1–2 mL with air alone. (Warmth of hand at this point is enough.)

Into dried residue pipet both 1 mL chromotropic acid reagent and 5 mL of the dil.  $\text{H}_2\text{SO}_4$ . Swirl vigorously to ensure that reagent contacts all of sample and place test tube in boiling  $\text{H}_2\text{O}$  bath. Stopper tube, lightly at first and then tighten. After 45 min in  $\text{H}_2\text{O}$  bath, remove, and cool to room temp. in beaker of cold  $\text{H}_2\text{O}$ . Pipet in 5 mL  $\text{H}_2\text{O}$ , mix well, and measure  $A$  in spectrophtr at 575 nm against reagent blank prepd similarly. From std curve, calc. piperonyl butoxide in aliquot.

*Thiram (Tetramethylthiuram Disulfide) (36)*  
*Official Final Action*

(Applicable to corn, apples, tomatoes, strawberries, celery, and similar fruits and vegetables)

29.165 *Principle*

Thiram is extd from sample with  $\text{CHCl}_3$ . Treatment with solid CuI results in formation of brown,  $\text{CHCl}_3$ -sol. Cu dimethyldithiocarbamate, and its  $A$  is measured at 440 nm. Other commonly used pesticides do not interfere, with exception of metal dithiocarbamates sol. in  $\text{CHCl}_3$ , such as ferbam or ziram. Moderate amts of color, waxes, and other extd plant matter do not interfere.

29.166 *Reagents*

(a) *Chloroform*.—Either reagent or tech. grade may be used.

(b) *Thiram std solns*.—(1) *Stock soln*.—500  $\mu\text{g/mL}$ . Dissolve 50.0 mg thiram (available from E. I. du Pont de Nemours & Co., Biochemicals Dept., 1007 Market St, Wilmington, DE 19898) in  $\text{CHCl}_3$  and dil. to 100 mL with  $\text{CHCl}_3$ . (2) *Working soln*.—25  $\mu\text{g/mL}$ . Dil. 5 mL stock soln to 100 mL with  $\text{CHCl}_3$ .

(c) *Cuprous iodide*.—If not available, prep. as follows: To soln of 10 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in ca 100 mL  $\text{H}_2\text{O}$ , slowly add excess of KI soln. Remove liberated  $\text{I}_2$  by adding  $\text{Na}_2\text{S}_2\text{O}_3$  soln in slight excess. Filter, and wash ppt thoroly with  $\text{H}_2\text{O}$  and with alcohol. Dry at room temp. and crush to fine powder.

(d) *Attapulgis clay*.—Available from MC/B Manufacturing Chemists, No. AX1799.

29.167 *Apparatus*

(a) *Spectrophotometer*.—Suitable for measuring  $A$  in UV and at 440 nm.

(b) *Glassware*.—Avoid contamination by rinsing with  $\text{CHCl}_3$  and drying before use. Rinse app. that may have contained CuI from previous detns with dil. acid,  $\text{H}_2\text{O}$ , alcohol, and  $\text{CHCl}_3$ .

29.168 *Preparation of Standard Curve*

(To minimize errors due to evapn of solv., keep flasks closed as much as possible, and cover funnels with watch glasses during filtrations.)

Using buret, add 2.0, 5.0, 10.0, and 15.0 mL working std soln to 25 mL vol. flasks. Dil. to vol. with  $\text{CHCl}_3$ , and mix. Solns contain 2, 5, 10, and 15  $\mu\text{g}$  thiram/mL, resp.

Transfer ca 10 mL portions of std solns to 125 mL g-s erlenmeyers, add 10 mg CuI to each, stopper, and let stand 1 hr with occasional mixing. Filter, using 9 cm quant. paper, and read  $A$  at 440 nm against  $\text{CHCl}_3$  as ref. Plot  $A$  against thiram concn in  $\mu\text{g/mL}$ .

29.169 *Isolation*

(Avoid contact of solv. with rubber.)

(a) *Corn*.—Ext 200 g by shaking with 100 mL  $\text{CHCl}_3$  5 min in 500 mL g-s erlenmeyer. Decant ext thru small funnel (to retain corn kernels) into flask.

★ Surplus method—see inside front cover.

(b) *Apples, pears, and similar firm fruits.*—Weigh 2–3 kg into clean, dry jar (ca 3 gal.; 11 L). Add 500 mL  $\text{CHCl}_3$  and stopper with tight-fitting cork, wooden bung, or plastic screw cap faced with gasket of sheet cork or other suitable solv.-resisting material. Ext 5 min by tumbling or other agitation. Decant ext into flask.

(c) *Tomatoes, berries, and similar soft fruits and vegetables.*—Weigh 1–3 kg into suitable container. Add 500 mL  $\text{CHCl}_3$  and stopper with solv.-resisting closure. Ext 5 min by gentle shaking and decant into g-s erlenmeyer thru loose plug of glass wool.

(d) *Celery.*—Cut 2–3 kg into 3–8 cm pieces. Mix thoroly and ext 500 g sample with 500 mL  $\text{CHCl}_3$  as above.

Add anhyd.  $\text{Na}_2\text{SO}_4$ , ca 5 g/100 mL, to decanted ext. Stopper flask, shake 5 min, and filter thru folded Whatman No. 12, or equiv., paper.

## 29.170

### Determination

(Thiram in  $\text{CHCl}_3$  soln, particularly in presence of plant extrac-tives, may decompose. Make detns as soon as possible.)

Transfer ca 10 mL filtered ext to g-s erlenmeyer and develop color as in 29.168, beginning "... add 10 mg  $\text{CuI}$  ..." As ref., use another portion of filtered ext., untreated with  $\text{CuI}$ . From std curve, obtain thiram concn in  $\mu\text{g/mL}$ . If developed color is too intense, dil. with  $\text{CHCl}_3$ , making similar diln of ref. ext, and multiply thiram value found by appropriate diln factor.

$\text{ppm Thiram} = (\mu\text{g thiram/mL}) \times \text{mL } \text{CHCl}_3 \text{ used for extn/g sample.}$

## 29.171

### Qualitative Test

Adjust concn of ext, 29.169, if necessary, to 10–15  $\mu\text{g}$  thiram/mL by evapn on steam bath or by diln with  $\text{CHCl}_3$ . Add 0.25–1.0 g Attapulugus clay, depending on color of ext, to 50 mL of adjusted ext in beaker. Mix well and filter thru Whatman No. 12 folded paper, or equiv. Transfer 25 mL filtrate to g-s erlenmeyer, add 0.2 mL ca 0.1N  $\text{AgNO}_3$  to ppt thiram and other  $\text{CHCl}_3$ -sol. dithiocarbamates, stopper, and shake vigorously 30 sec. Add ca 1 g anhyd.  $\text{Na}_2\text{SO}_4$  and shake 30 sec. Let settle, decant carefully into 1 cm quartz cell, and use as ref. soln, adjusting to 0.4 at 350 nm. Det. UV absorption curve over range 250–350 nm on clarified and filtered ext untreated with  $\text{AgNO}_3$ . Thiram gives curve with plateau at 270–283 nm, dropping sharply after peaking at ca 283. Ferbam and ziram give characteristic curves distinguishable from thiram.

## 30. Spices and Other Condiments

### SPICES

#### 30.001 Preparation of Sample—Procedure

Grind sample to pass sieve with circular openings 1 mm diam. and mix thoroly. Since most spices lack uniformity and tend to stratify, use extreme care in weighing out portion for analysis. Stir material thoroly and weigh out the 2 g samples, using spoon with ca 2 g capacity. Dip spoonful from center of material, being careful to take ca required wt so as to avoid adding to or taking from portion on scale pan. In detn of starch in spices by diastase method, further reduce subsample as nearly as possible to impalpable powder.

#### Extractable Color (7)—Official First Action

(Applicable to capsicums and oleoresin paprika)

#### 30.002

##### Apparatus and Reagents

(a) *Spectrophotometer*.—Capable of accurately measuring  $A$  at 460 nm; with 1 cm stoppered cells.

(b) *Std color soln.*—Dry  $\text{CoSO}_4(\text{NH}_4)_2 \cdot 6\text{H}_2\text{O}$  1 week in desiccator over Drierite. Dissolve 0.3005 g  $\text{K}_2\text{Cr}_2\text{O}_7$  and 34.960 g dried  $\text{CoSO}_4(\text{NH}_4)_2 \cdot \text{SO}_4$  in 1.8M  $\text{H}_2\text{SO}_4$  and dil. to 1 L with 1.8M  $\text{H}_2\text{SO}_4$ .  $A$  in 1 cm cell at 460 nm = 0.600.

(c) *Glass reference std.*—NBS SRM 2030, glass filter with  $A$  specified by NBS in range 0.4–0.6 at 465 nm.

#### 30.003

##### Determination

(a) *Capsicums*.—Grind capsicums to pass No. 40 (No. 18 if NBS std is used) sieve. Place accurately weighed sample contg 70–100 mg ground capsicums in 100 ml vol. flask, dil. to vol. with acetone, and stopper tightly. Shake flask and let stand 4 hr (16 hr if NBS std is used) at room temp. in dark. Shake flask again and let particles settle 2 min. Transfer portion of ext to spectrophtr cell with 10 mL pipet.

Det.  $A$  of sample at 460 nm, using acetone as blank. Det.  $A$  of std color soln at 460 nm, using 1.8M  $\text{H}_2\text{SO}_4$  as blank, or of NBS std at 465 nm.

(b) *Oleoresin, using std color soln.*—Weigh, to nearest 0.1 mg, 50–80 mg sample on 5 cm sq glassine paper. Place paper with sample in 100 mL vol. flask and dil. to vol. with acetone. Ext  $\geq 15$  min with occasional shaking. Using 10 mL pipet, transfer 10 mL ext into another 100 mL vol. flask and dil. to vol. with acetone. Filter dild ext thru Whatman No. 40 paper, or equiv.; discard first 10–15 mL filtrate. Decant portion of filtrate into cell and measure  $A$  at 460 nm against acetone.

(c) *Oleoresin, using NBS std.*—Weigh, to nearest 0.1 mg, 70–100 mg sample and transfer to 100 mL vol. flask. Dil. to vol. with acetone, shake, and let stand 2 min. Pipet 10 mL ext into another 100 mL vol. flask, dil. to vol. with acetone, and shake. Transfer portion to cell and measure  $A$  at 460 nm against acetone.

#### 30.004

##### Calculations

To correct for instrument and cell variations, calc. correction factor,  $I_t = 0.600/A$  of std color soln at 460 nm, or  $I_t =$  declared  $A$  of NBS std at 465 nm/actual  $A$  of NBS std at 465 nm. Redet.  $I_t$  each time spectrophtr is turned on.

Range of  $A$  should be 0.30 to 0.70. Dil. exts with  $A > 0.70$  with acetone to  $\frac{1}{2}$  original concn. Discard exts with  $A < 0.30$  and ext larger sample.

ASTA color value for capsicum

$$= [(A_{\text{ext}} \text{ at } 460 \text{ nm}) \times (16.4 I_t)]/\text{g sample}$$

ASTA color value for oleoresin

$$= [(A_{\text{ext}} \text{ at } 460 \text{ nm}) \times (164 I_t)]/\text{g sample}$$

where 16.4 and 164 are conversion factors to American Spice Trade Association (ASTA) color values.

EOA (Essential Oils Association) color value for oleoresin =  $[(A_{\text{ext}} \text{ at } 460 \text{ nm}) \times 61,000 I_t]/\text{g sample}$ ;

100 EOA color units = 2.69 ASTA color units.

#### 30.005 Moisture (2)—Official Final Action

Clean distg tube receiver and condenser, 7.004, with chromic acid soln, rinse thoroly with  $\text{H}_2\text{O}$  and then with ca 0.5N alc. KOH, and drain 10 min. Before cleaning, remove connecting stopper from condenser, to keep it dry. Place 40 g spice in distg flask and proceed as in 7.005.

#### 30.006 Ash (2)—Official Final Action

(a) *Most spices*.—Accurately weigh ca 2 g sample in flat-bottom dish, preferably Pt. Place dish in entrance of open furnace so that sample fumes off without catching fire. Then ash in furnace 30 min at 550°, break up ash with several drops  $\text{H}_2\text{O}$ , evap. carefully to dryness, and heat in furnace 30 min. If previous wetting showed ash to be C-free, remove dish to desiccator contg fresh, efficient desiccant ( $\text{H}_2\text{SO}_4$  or anhyd.  $\text{Mg}(\text{ClO}_4)_2$  is satisfactory), let cool to room temp., and weigh soon. If first wetting showed C, repeat wetting and heating until no specks of C are visible; then heat 30 min after disappearance of C. If C persists, leach ash with hot  $\text{H}_2\text{O}$ , filter thru quant. paper, wash paper thoroly, transfer paper and contents to ashing dish, dry, and ignite at 550° until ash is white. Cool dish, add filtrate, evap. to dryness on steam bath, and heat in furnace 30 min. Cool, and weigh as previously.

(b) *Nutmeg, mace, ginger, and cloves*.—Proceed as in (a), but heat at 600°.

(c) *Ground mustard or mustard flour*.—Ignite as in (a) and heat 30 min at 550°. Leach ash with hot  $\text{H}_2\text{O}$ , filter, and wash thoroly. Transfer paper and contents to ashing dish, dry, and heat in furnace 30 min. Remove dish, let cool, add 5–10 drops  $\text{HNO}_3$ , evap. to dryness, and heat in furnace 30 min. Repeat  $\text{HNO}_3$  and heating treatment until residue is white. Add filtrate, evap. to dryness, and heat in furnace 30 min. Cool, and weigh as in (a).

#### 30.007 Soluble and Insoluble Ash—Official Final Action

Proceed as in 31.015, using ash obtained in 30.006.

#### 30.008 Ash Insoluble in Acid—Official Final Action

Boil  $\text{H}_2\text{O}$ -insol. residue, 30.007, or total ash, 30.006, with 25 mL HCl (2+5) 5 min, covering dish with watch glass to prevent spattering; collect insol. matter on gooch or ashless filter, wash with hot  $\text{H}_2\text{O}$  until washings are acid-free, ignite until C-free, cool, and weigh.

#### 30.009 Calcium in Ash—Official Final Action

Ignite 2–4 g sample as in 30.006, digest with hot HCl (2 + 5), evap. to dryness, moisten dry residue with dil. HCl, and again evap. to dryness to make  $\text{SiO}_2$  insol. Treat residue with 5–10 mL HCl, add ca 50 mL  $\text{H}_2\text{O}$ , let stand on  $\text{H}_2\text{O}$  bath few min, filter, and

wash insol. residue with hot H<sub>2</sub>O. Det. CaO in combined filtrate and washings as in 3.015.

### 30.010 Nitrogen—Official Final Action

Proceed as in 2.057. Use 1 g sample for black or white pepper.

### 30.011 Nitrogen in Nonvolatile Ether Extract Official Final Action

(For black and white peppers)

(Caution: See 51.009, 51.011, 51.039, and 51.054.)

Ext 10 g pepper 20 hr in continuous extn app. with absolute ether, collecting ext in weighed 250 mL flask. Evap. ether, and dry first at 100° and finally to min. wt at 110°. Det. N in weighed ext as in 2.057, digesting in same flask used for extn.

Crude piperine = N × 20.36.

### 30.012 Volatile and Nonvolatile Ether Extract (3) Official Final Action

(Not suitable for detn of volatile ether ext in spices high in volatile oils, such as cloves)

(Caution: See 51.009, 51.011, 51.039, and 51.054.)

Ext 2 g ground material 20 hr in continuous extn app. with anhyd. ether. Transfer ext to weighed capsule and let evap. at room temp. Store 18 hr over H<sub>2</sub>SO<sub>4</sub> and weigh total ether ext. Heat ext gradually and then to min. wt at 110°. Loss is volatile ether ext; residue is nonvolatile ether ext.

### 30.013 Alcohol Extract (4)—Official Final Action

Place 2 g sample in 100 mL vol. flask and dil. to vol. with alcohol. Stopper, shake at 30 min intervals during 8 hr, and let stand 16 hr longer without shaking. Filter ext thru dry paper, evap. 50 mL aliquot filtrate to dryness in flat-bottom dish on steam bath, and heat to min. wt at 110°.

### 30.014 Copper-Reducing Substances by Direct Acid Hydrolysis—Official Final Action

Ext 4 g sample with five 10 mL portions ether on filter that will completely retain smallest starch granules. Let ether evap. from residue and wash with 150 mL alcohol, 10% by vol.

To avoid clogging of filter by glutinous mass that may result from washing with H<sub>2</sub>O or dil. alcohol, omit all preliminary washings with cassia buds and cinnamon.

Carefully wash residue from paper into 500 mL flask with 200 mL H<sub>2</sub>O, using small wash bottle and gently rubbing paper with tip of finger. Hydrolyze and det. Cu-reducing material as in 8.019. Express results in terms of starch.

### Starch—Official Final Action

#### 30.015 Method I

Ext 4 g finely pulverized sample with ether and 500 mL 10% alcohol as in 30.014, and det. starch by diastase method, 31.101.

#### 30.016 Method II

(Applicable to dry mustard)

Treat 2–3 g dry mustard flour as in 30.041.

### 30.017 Crude Fiber—Official Final Action

Proceed as in 7.065, and, before drying the crude fiber, remove all ether extractives by successive washings with ether.

### Tannin (5)—Official Final Action

(For cloves and allspice)

#### 30.018

#### Reagents

(a) *Oxalic acid soln.*—0.1N. 1 mL = 0.006235 g quercitannic acid or 0.0008 g O absorbed.

(b) *Potassium permanganate std soln.*—Dissolve 1.333 g KMnO<sub>4</sub> in 1 L H<sub>2</sub>O and stdze against (a).

(c) *Indigo soln.*—Dissolve 6 g Na indigotin disulfonate in 500 mL H<sub>2</sub>O by heating; cool, add 50 mL H<sub>2</sub>SO<sub>4</sub>, dil. to 1 L, and filter.

#### 30.019

#### Determination

(Caution: See 51.009, 51.011, 51.039, and 51.054.)

Ext 2 g sample 20 hr with anhyd. ether. Boil residue 2 hr with 300 mL H<sub>2</sub>O, cool, dil. to 500 mL, and filter. Measure 25 mL of this infusion into 2 L porcelain dish; add 20 mL indigo soln and 750 mL H<sub>2</sub>O. Add std KMnO<sub>4</sub> soln, 1 mL at time, until blue soln changes to green; then add few drops at time until soln becomes golden yellow. Similarly titr. mixt. of 20 mL indigo soln and 750 mL H<sub>2</sub>O. Multiply difference between 2 titrns by desired factor, 30.018(a), to obtain quercitannic acid or O absorbed.

### Volatile Oil (6)—Official Final Action

#### 30.020

#### Apparatus

(a) *Volatile oil traps.*—Clevenger-type with 3 joints: (1) For oils with densities near or less than that of H<sub>2</sub>O; and (2) for oils with densities greater than that of H<sub>2</sub>O. (See Fig. 30:01.)

(b) *Flask with magnetic stirrer.*—1 L r-b, shortneck with 29/42 joint; heavy duty mag. stirrer with egg-shaped stirring bar.

#### 30.021

#### Determination

Prep. sample as in 30.001, except use No. 20 sieve. Take precautions to prevent loss of volatile oil from heating during grinding.

Transfer enough weighed sample to 1 L flask to yield 2–4 mL volatile oil. Add H<sub>2</sub>O to fill flask ca half full. Insert stirring bar and place flask in heating mantle set over mag. stirrer. Add antifoam agent, such as Dow Corning Antifoam Emulsion, ca size of pea. Clean trap and condenser with chromic acid soln just before use and fill trap with H<sub>2</sub>O. Set app. so that condensate will not drop directly on surface of liq. in trap but will run down

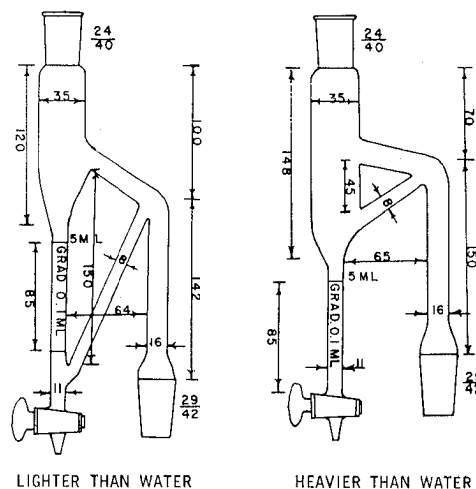

FIG. 30:01—Apparatus for volatile oil in spices (dimensions in mm)

side. Start stirrer and heat mantle thru variable transformer set at 90 volts ( $\leq 3$  amp).

If oil seps in graduated portion of trap or clings to walls, add several drops satd aq. detergent soln thru top of condenser. Repeat, if necessary (usually once is enough). Distil 10 min after adding detergent to wash it out of trap. When density of oil is nearly 1, as in cassia, or if oil seps into 2 fractions in trap, as in nutmeg and allspice, add 1 mL xylene, accurately measured, to lighter-than- $H_2O$  trap.

Distil until 2 consecutive readings taken at 1 hr intervals show no change in oil content ( $\geq 6$  hr). Cool, and read vol. collected oil. If xylene was added, subtract its vol., and report oil as mL/100 g spice.

If required for further examination, drain oil into g-s tube or graduate, sepg from aq. layer. Let oil stand until clear, or dry with min. amt of anhyd.  $Na_2SO_4$ , and let settle before detg chem. and physical characteristics. Store in refrigerator.

### 30.022 Specific Gravity of Volatile Oil Official Final Action

Det. sp gr at 25/25° as in 28.003 and 28.004, using 1 mL Sprengel tube.

### 30.023 Refractive Index of Volatile Oil Official Final Action

See 28.007 and 28.008.

### 30.024 Eugenol in Volatile Oil—Official Final Action

Measure 2 mL volatile oil (transfer pipet) into Babcock milk bottle, 16.060(a). Add 20 mL 3% KOH soln, shake mixt. 5 min, heat 10 min in boiling  $H_2O$  bath, remove, and cool to room temp. When liqs sep. completely, add enough KOH soln to bring residual oil within graduated portion of neck and note vol. Calc. % by vol. from difference between vol. sample used and residual oil.

### 30.025 Volatile Oil and Resin in Ginger (7) Official Final Action

(Caution: See 51.011, 51.039, and 51.054.)

Place 50 g ground ginger in Soxhlet extractor and ext completely with ether (ca 4 hr). Transfer ext to 300 mL flask and evap. ether on steam bath until solv. is no longer detected. Add 50 mL  $H_2O$  to residue and det. yield of volatile oil (using trap for oils lighter than  $H_2O$ ), sp gr, and refractive index, as in 30.021–30.023.

Transfer residue in flask to separator and ext resin with ether. Transfer to tared beaker, evap. ether on steam bath, and dry to const wt in vac. desiccator.

### Volatile Oil in Mustard Seed (8)—Official Final Action

#### 30.026 Apparatus and Reagents

(a) *Gas chromatograph*.—With flame ionization detector. Approx. operating conditions: Temps (°)—column 145, detector 200, injector 160; N flow rate 100 mL/min. Optimum conditions are obtained when  $\geq 10$  cm peak is obtained for 8  $\mu$ L std soln injection.

(b) *Column and packing*.—3.7 m (12')  $\times$  4 mm id, 5% Carbowax 4000 on Fluoropak 80, 20–40 mesh.

(c) *Allyl isothiocyanate std soln*.—30.5 mg/100 mL. Measure 30  $\mu$ L allyl isothiocyanate in 50  $\mu$ L syringe with 0.5% accuracy. Add to 50 mL 10% alcohol in 100 mL vol. flask and shake intermittently until dissolved. Dil. to vol. with  $H_2O$ .

#### 30.027

#### Determination

Grind  $\geq 15$  g seed to pass thru No. 20 sieve. Immediately weigh 6.0 g into 300 mL erlenmeyer, add 150 mL 5% alcohol, stopper tightly, and stir mag.  $90 \pm 5$  min in 37°  $H_2O$  bath.

(a) *Gas chromatographic method*.—Distil ca 70 mL into 100 mL vol. flask contg 20 mL 5% alcohol, taking care that end of condenser dips below surface of soln. Dil. to vol. with  $H_2O$ . Inject 4–10  $\mu$ L into gas chromatograph. Compare peak ht of sample with that from same vol. std soln.

(b) *Titration method*.—Distil ca 60 mL into 100 mL vol. flask contg 10 mL  $NH_4OH$  (1+2), taking care that end of condenser dips below surface of soln. Add 20 mL 0.1N  $AgNO_3$  to distillate and let stand overnight (Caution: See 51.044); heat to bp on  $H_2O$  bath (boil behind safety barrier) to agglomerate  $Ag_2S$ , cool, dil. to 100 mL with  $H_2O$ , and filter. Acidify 50 mL filtrate with ca 5 mL  $HNO_3$  and titr. with 0.1N  $NH_4SCN$ , using 5 mL 10%  $FeNH_4(SO_4)_2 \cdot 12H_2O$  soln as indicator. 1 mL 0.1N  $AgNO_3$  = 0.004958 g allyl isothiocyanate.

Note: Before discarding  $Ag_2S$  and filter paper, treat with 25 mL 1N  $Na_2S_2O_5$  in 1N NaOH.

#### Microscopic Examination—Procedure

#### 30.028

#### General (9)

Adulterants of vegetable origin in spices are best detected microscopically. General knowledge of vegetable histology and microscopic appearance of spices and spice adulterants is essential. Some std works on these subjects (9) are listed in Selected References.

#### 30.029

#### Reagents

(a) *Acidified chloral hydrate-glycerol soln*.—Dissolve 45 g chloral hydrate crystals in 25 mL HCl (1+8) and 10 mL glycerol.

(b) *Chloral hydrate soln*.—Dissolve 8 parts by wt chloral hydrate crystals in 5 parts  $H_2O$ .

(c) *Ferric acetate or chloride soln*.—Freshly prepd 1% aq. soln.

(d) *Iodine-potassium iodide soln (iodine soln)*.—Dissolve 0.5 g I and 1.5 g KI in very small amt of  $H_2O$  and dil. to 25 mL.

(e) *Iodine-potassium iodide in zinc chloride soln*.—Dissolve 100 g  $ZnCl_2$  in 60 mL  $H_2O$  in g-s bottle and add 20 g KI and 0.5 g I. Leave few I crystals in bottle to ensure satn and let soln stand few hr before use. Soln keeps for months. If color developed in tissue is too deep blue, dil. reagent slightly.

(f) *Millon reagent*.—See 7.125(g).

(g) *Potassium chlorate macerating soln*.—Mix 0.5 g  $KClO_3$  with 50 mL  $HNO_3$  (1+1) as needed.

(h) *Potassium hydroxide soln*.—Dissolve 5 g KOH in  $H_2O$  and dil. to 100 mL.

(i) *Sudan IV, saturated alcoholic soln*.—Approx. 0.09%.

#### 30.030

#### Apparatus

(a) *Wide-field stereoscopic microscope*.—Instrument with ca 10 to 60 $\times$  magnification is useful for preliminary sepn.

(b) *Compound microscope*.—Instrument with ca 100 to 400 $\times$  magnification. Eyepiece micrometer, mech. stage, and polarizing microscope are desirable for special types of work.

(c) *Sieves*.—Series of std mesh sieves from No. 10 to 100, and sieve with circular openings 1 mm diam.

(d) *Slides, cover glasses, needles, forceps, etc.*

#### 30.031

#### Preparation of Sample

Reduce 1 portion to fine powder in mortar. Sep. another portion into several grades of fineness by sieves of different

mesh or by jarring on sheet of paper. In coarser grades, fragments of suspicious nature may often be seen with naked eye or under simple microscope; these should be picked out for subsequent examination under compd microscope.

**30.032****Examination**

Mount small amt ground sample in H<sub>2</sub>O and examine under compd microscope with both ordinary and polarized light. This gives general information as to nature of material and serves for detection and identification of starch granules and various tissues. Place small drop of I-KI soln at edge of cover glass, draw it into prepn with piece of filter paper placed at opposite edge of cover glass, and examine again. Starch granules are colored blue or blue-black; cellulose, yellow; and proteins, either brown or yellow.

Similarly, draw little KOH soln under cover glass and again examine. This treatment gelatinizes starch granules, dissolves proteins, saponifies fats, and in other ways clears prepn. It also imparts reddish color to tannins. If this treatment does not clear tissues satisfactorily, treat fresh portion for short time with acidified chloral hydrate-glycerol soln, heating gently, if necessary, or for some hours with the chloral hydrate soln.

Also examine crude fiber obtained in chem. analysis, as stone cells and other tissues are shown distinctly in this material.

To isolate stone cells, bast fibers, and other thick-wall cells, macerate portion of sample in KClO<sub>3</sub> macerating soln, varying proportions of KClO<sub>3</sub> and HNO<sub>3</sub> and heating long enough to secure desired results.

To distinguish cellulose from infiltrated substances (lignin, suberin, etc.), add freshly prepd I-KI in ZnCl<sub>2</sub> soln to H<sub>2</sub>O mount. Cellulose is colored blue, and infiltrated substances are yellow.

To distinguish fats, oils, essential oils, resins, latex, and wax from other cell contents, place small amt of tissue on slide, add 2 drops Sudan IV soln and 2 drops glycerol or acidified chloral hydrate-glycerol soln, and heat gently; these substances are stained red. Treat sep. portion of tissue with ether, pet ether, or alcohol. Ether and pet ether dissolve fats, oils, essential oils, resins, latex, and wax. Alcohol dissolves essential oils and resins but usually affects fats, oils, latex, and wax slowly or not at all.

Test for proteins by warming cautiously on slide with drop of Millon reagent. Proteins are partially decomposed, gradually acquiring brick red color. To study form of aleurone (protein) granules, which in some plants are quite as characteristic as starch granules, prep. mount in pure glycerol or oil.

Test for tannins and tissues impregnated with them by adding Fe(OAc)<sub>3</sub> or FeCl<sub>3</sub> soln. Both reagents give green or blue color with tannins, but Fe(OAc)<sub>3</sub> acts more slowly and is preferred.

Crystals of Ca oxalate (J. Amer. Pharm. Assoc. 12, 301(1923)) are recognized by their characteristic forms and by behavior to polarized light. To distinguish Ca oxalate from CaCO<sub>3</sub>, treat with HOAc, which does not affect oxalate but dissolves carbonate with effervescence. Both are sol. in HCl.

Powd charcoal and charred shells resist bleaching action of KOH, chloral hydrate, and KClO<sub>3</sub> macerating soln.

**PREPARED MUSTARD****30.033 Preparation of Sample—Procedure**

Transfer entire contents of container to dish large enough to permit thoro stirring and make whole mass homogeneous. Preserve in g-s bottle. Stir well each time before removing portion for analysis.

**30.034 Solids—Official Final Action**

Weigh 5 g sample into flat-bottom Pt dish; distribute evenly

over bottom of dish with little H<sub>2</sub>O, place on steam bath until mixt. appears dry, and heat in oven at 100° to min. wt.

**30.035 Total Chlorides (70)—Official Final Action**

Weigh 3–4 g sample from weighing bottle, place in 300 mL erlenmeyer, and add excess std 0.1*N* AgNO<sub>3</sub> (usually 30 mL is enough). Mix thoroly, add 15 mL HNO<sub>3</sub>, and bring to boil on hot plate. To boiling mixt. add 15 mL 5% KMnO<sub>4</sub> soln, 5 mL at time, rotating flask after each addn to mix contents. Add ca 50 mL H<sub>2</sub>O and filter into 200 mL vol. flask. Wash filter free of AgNO<sub>3</sub> and dil. to vol. with H<sub>2</sub>O. Mix thoroly and titr. 100 mL aliquot with 0.1*N* KSCN, using 2 mL satd Fe alum soln as indicator. Calc. chlorides as NaCl.

**30.036 Ether Extract—Official Final Action**

(*Caution: See 51.009, 51.011, 51.039, and 51.054.*)

Weigh 10 g sample into SiO<sub>2</sub>, Al, or porcelain drying dish and mix with ca 30 g sand. Heat on H<sub>2</sub>O bath until mixt. appears dry; then finish drying in oven at 100°. Grind until all lumps are broken up, and det. ether ext by extg 16 hr with anhyd. ether in Soxhlet extractor with Whatman single thickness or other close-texture thimble. Dry ext 30 min at 100°, cool, and weigh.

**30.037 Total Nitrogen—Official Final Action**

Det. N as in 2.057, using 5 g sample.

**30.038 Acidity—Official Final Action**

Weigh 10 g sample into 200 mL vol. flask, dil. to vol. with H<sub>2</sub>O, shake, filter thru dry paper, and det. acidity in 100 mL by titrn with 0.1*N* alkali, using phthln. Express result as HOAc. 1 mL 0.1*N* alkali = 0.0060 g HOAc.

**30.039 ★ Sucrose—Official First Action ★**

See 28.036–28.037, 10th ed.

**Starch—Official Final Action****30.040****Reagents**

(a) *Calcium chloride soln.*—30 g/100 mL soln adjusted to 0.01*N* alky.

(b) *Alcoholic sodium hydroxide soln.*—Mix 70 mL alcohol with 30 mL 0.1*N* NaOH.

(c) *Iodine-potassium iodide soln.*—Dissolve 2 g I and 6 g KI in 100 mL H<sub>2</sub>O.

**30.041****Determination**

Place 5 g prepd mustard in 500 mL erlenmeyer and pipet in 100 mL CaCl<sub>2</sub> soln, swirling flask gently until all lumps are broken. Add calcd vol. 1*N* NaOH to neutze acid in wt prepd mustard taken for analysis. Add glass beads. Connect to reflux condenser, first wetting inside of condenser and stopper with H<sub>2</sub>O and draining 1 min. Heat gently (on asbestos board with center hole) to avoid initial foaming, and boil 15 min.

Leaving condenser connected, cool flask to room temp. in pan of cold H<sub>2</sub>O. Remove flask, stopper, and shake vigorously. Pour contents into centr. bottle and centr. 5 min at 1500 rpm. Withdraw as much as possible of partially clarified middle layer (ca 75 mL) and filter thru 11 cm circle of absorbent cotton ca 5 cm thick placed in 60° funnel. Pipet 50 mL filtrate into second centr. bottle contg 150 mL alcohol, stopper, and shake vigorously several min. Centr. at 1500 rpm until clear (ca 5 min).

★ Surplus method—see inside front cover.

Decant liq. thru asbestos pad in Caldwell crucible, using suction, without transferring starch to crucible. Transfer pad to same centr. bottle, and rinse all particles adhering to crucible into bottle with H<sub>2</sub>O. Add several glass beads and H<sub>2</sub>O to ca 100 mL. Stopper and shake vigorously until ppt is as finely dispersed as possible. Add slight excess I-KI soln (2–3 mL) and 30 mL satd (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln. Stopper and shake bottle. Rinse particles adhering to stopper into bottle, and centr. until clear.

Decant supernate, with suction, thru asbestos pad in Caldwell crucible. Add 50 mL alc. NaOH soln to ppt in centr. bottle. Stopper and shake vigorously. Wash stopper with 70% alcohol. Centr. and decant supernate thru same pad as before. Repeat treatment with the NaOH soln until practically all blue disappears (usually 2–3 treatments). Without centrfg, transfer contents of bottle to Caldwell crucible, using 70% alcohol. Aspirate until pad is dry; then transfer pad to 500 mL Kjeldahl flask. Rinse bottle and crucible with 10 mL HCl (sp gr 1.1029) followed by five 10 mL portions H<sub>2</sub>O, carefully removing all adhering particles. Attach Kjeldahl flask to reflux condenser, first adding glass beads to lessen bumping. Place on asbestos board with center hole and boil 1 hr. Cool, neutze with NaOH (1+1) (Me orange), and filter into 200 mL vol. flask; rinse flask and filter thoroly, and dil. to vol. with H<sub>2</sub>O. Mix well, and det. glucose in 50 mL aliquot by **31.038**. (Blank on Fehling soln should be ≤0.3 mg.)

% Starch =  $[g \text{ glucose} \times 0.9(100 + V + W) \times 8]/\text{wt sample}$ , where  $V$  = mL 1*N* NaOH used to neutze acidity, **30.038**, and  $W$  = g H<sub>2</sub>O in sample taken (calcd from solids, **30.034**).

### 30.042 Crude Fiber (17)—Official Final Action

Weigh 10 g sample and transfer to 8 oz nursing bottle with 50 mL alcohol, stopper, and shake vigorously. Add 40 mL ether, shake, and let stand ca 5 min, shaking occasionally. Centr. and decant alcohol-ether mixt. Treat twice more with 40 mL portions ether, shaking, centrfg, and decanting as before. Rest bottle on its side for short time, without heat, to let most of ether evap. Transfer material to 500 mL erlenmeyer, using 200 mL boiling H<sub>2</sub>SO<sub>4</sub>, **7.062(a)**, and proceed as in **7.065**, but in addn wash fiber with successive portions of ether before drying and weighing.

If preferred, treat sample with alcohol and ether in small beaker, transfer to hardened 11 cm filter paper, wash several times with ether, and transfer to 500 mL erlenmeyer with 200 mL boiling H<sub>2</sub>SO<sub>4</sub>.

### 30.043 Preservatives

See Chap. 20.

## DRESSINGS FOR FOODS (12)

### 30.044 Preparation of Sample—Procedure

(a) *Semisolid and emulsified dressings*.—Before removing any portion of sample for analysis, transfer to suitable container, such as glass fruit jar, of larger capacity than vol. of sample, and mix with spatula until homogeneous (2–3 min should be enough). Repeat mixing before each subsequent portion is removed for analysis if sample has stood for any appreciable time. For various detns, take approx. quantity directed and weigh. (Light 100 mL flask fitted with straight glass tube and oversized rubber bulb makes suitable weighing bottle.)

(b) *Separable dressings, small containers*.—Weigh bottle contg sample. Shake bottle 1 min, empty contents into high-speed blender, and let bottle drain 1 min. Weigh empty bottle to det. wt sample. Add 0.20 g egg albumen powder/100 g sample, cover blender, and blend 5 min; then transfer to suitable container of capacity larger than sample vol. Shake sample ca

20 times and stir with spatula or spoon ca 20 times before each portion is removed for analysis. Make all weighings immediately after sample prepn. Correct results for added emulsifier.

(c) *Separable dressings, large containers*.—Stir contents thoroly, adding 0.20 g egg albumen powder/100 g sample. Mech. stirrer of double-beater type is satisfactory. Continue stirring until powder is well dispersed thruout sample. Add sample in portions to high-speed blender and blend each portion ca 5 min. Transfer emulsified portions to jar of ca same size as original container and stir entire contents of sample to ensure uniform mixt. Transfer portion of prepd sample to suitable jar (ca 500 mL; 1 pt). Proceed as in (b), beginning "Shake sample ca 20 times . . ."

### 30.045 Total Solids—Official Final Action

Use 2 g sample and proceed as in **17.007(a)**.

### 30.046 Reducing Sugars Before Inversion Official Final Action

Weigh 20 g sample into wide-mouth 4 oz (120 mL) bottle and ext oil by adding ca 80 mL pet ether, shaking, and centrfg. Draw off as much as possible of pet ether soln (conveniently done by using suction and short-stem pipet), and repeat treatment with pet ether until all oil is removed (indicated by absence of color in solv.; usually 4 extns are required). Reserve ether soln for identification of oil. Remove pet ether from residue with air current and transfer residue with H<sub>2</sub>O to 100 mL vol. flask. Add 5–10 mL *fresh soln of HPO<sub>3</sub>* (remove any white coating on HPO<sub>3</sub> by rinsing with H<sub>2</sub>O, dissolve 5 g transparent lumps or sticks in cold H<sub>2</sub>O, and dil. to 100 mL), mix thoroly, dil. to vol., and filter. Transfer 80 mL filtrate, or as large aliquot as possible, to 100 mL vol. flask; neutze with NaOH soln (1+1), using phthln; cool, dil. to vol., and det. reducing sugars on aliquot as in **31.038**. Calc. to invert sugar.

With dressings, particularly those contg starch, that cannot be clarified by above method, remove oil as in **16.059**, using 1 mL NH<sub>4</sub>OH and 5 mL alcohol/g sample; transfer residue to 250 mL vol. flask with 50% alcohol, and proceed as in **7.079** and **31.038**.

### 30.047 Reducing Sugars After Inversion Official Final Action

Invert aliquot of soln, **30.046**, as in **31.026(b)** or (c), nearly neutze with NaOH soln (1+1), and det. reducing sugars in inverted soln as in **31.038**. Calc. to invert sugar from **52.019**.

### 30.048 Sucrose—Official Final Action

Subtract % invert sugar obtained before inversion, **30.046**, from that obtained after inversion, **30.047**, and multiply difference by 0.95.

### 30.049 Total Acidity—Official Final Action

Weigh ca 15 g sample into 500 mL erlenmeyer, dil. to ca 200 mL, and shake until all lumps are thoroly broken up. Tit. with 0.1*N* NaOH, using phthln, and calc. as HOAc. To recognize end point, have duplicate sample at hand so that, by comparison, first change of color may be noted.

### 30.050 Total Nitrogen—Official Final Action

Accurately weigh ca 15 g sample into 500 mL Kjeldahl flask and place on steam bath until egg is thoroly cooked and oil seps readily. Cool, and add ca 50 mL pet ether; mix, and decant pet ether thru small filter. Repeat pet ether treatment twice, rinsing out as much oil as possible. Wash filter with pet ether

and add filter paper to sample in flask. Det. N, using 50 mL  $\text{H}_2\text{SO}_4$  (more, if necessary) for digestion, as in 2.057.

### 30.051 Total Phosphorus—Official Final Action

Use 10 g sample and proceed as in 17.023(a) and 17.024, except use Pt dish in place of beaker and burn off oil before ashing in furnace.

### 30.052 Total Fat—Official Final Action

(Caution: See 51.011, 51.039, 51.054, and 51.073.)

Thoroughly mix sample, and accurately weigh ca 1 g, by difference, into Mojonnier tube. Add 10 mL HCl, shake, set tube in  $\text{H}_2\text{O}$  bath heated to  $70^\circ$ , and bring to bp. Boil 30 min, shaking tube thoroughly every 5 min. Remove from  $\text{H}_2\text{O}$  bath, add  $\text{H}_2\text{O}$  to fill lower bulb of tube (but not neck), and cool to room temp.

To mixt. in Mojonnier tube add 25 mL ether and shake vigorously  $\geq 1$  min. Add 25 mL pet ether and again shake vigorously  $\geq 1$  min. To break emulsion centr. 5–10 min at ca 300 rpm. Decant ether-fat soln into flask, contg porcelain chips or glass beads, that has been dried at  $100^\circ$ , allowed to cool in air to constant wt, and weighed against similar flask similarly treated as counterpoise. Rinse off mouth of tube with small vol. ether after each decantation, letting ether run into flask. Repeat ether extns twice, using only 15 mL of each ether for second and third extns. Again shake vigorously after addn of each ether and centr. If necessary in order to decant all ether-fat soln after first extn, add more  $\text{H}_2\text{O}$  prior to second decantation.

Slowly evap. combined ether solns in flask, dry ca 90 min at  $100^\circ$  (placing counterpoise in oven at same time), cool in air to const wt, and weigh.

### 30.053 Identification of Oil—Official Final Action

Proceed as in Chapter 28, using oil obtained by evapg pet ether exts from detn of reducing sugars, 30.046. (Caution: See 51.011 and 51.073.)

### 30.054 Gums in Mayonnaise and French Dressing (13) Official Final Action

(Not applicable in presence of starch)

(Caution: See 51.082.)

Transfer 100 g sample to 250 mL beaker, add 35–40 mL hot  $\text{H}_2\text{O}$ , and mix thoroughly. Heat to  $65\text{--}70^\circ$  in  $\text{H}_2\text{O}$  bath, add 10 mL 50% trichloroacetic acid soln, and maintain at  $65\text{--}70^\circ$  until emulsion shows signs of breaking (never  $>10$  min). Transfer mixt. to 250 mL (8 oz) nursing bottle and insert pipet guard (JAOAC 20, 529(1937)) (wide-bore glass tube long enough to reach almost to bottom of centr. bottle, with lower end loosely stoppered; tube is held in place by slotted rubber stopper). Centr. 15–20 min at ca 1200 rpm. (This should sep. mixt. into lower aq. layer and upper oily layer, with layer of curd between. If sepn does not occur, add 30–40 mL toluene, mix, and repeat centrfg.) Using pipet inserted thru pipet guard, remove as much aq. layer as possible, and filter it into 600 mL beaker. Add 5 vols alcohol to filtrate and let stand overnight to ppt gums.

Decant or pipet off enough alcohol to leave  $\leq 225$  mL, transfer contents of beaker to 250 mL (8 oz) nursing bottle, centr. until gum settles to bottom, and decant supernate alcohol as completely as possible. Dissolve residue in  $\leq 50$  mL hot  $\text{H}_2\text{O}$ , add 1 or 2 mL HOAc, and ppt by adding alcohol to 250 mL mark on nursing bottle. Let stand overnight, or until ppt flocculates, centr. at 1200 rpm, and decant alcohol. (Heavy flocculent ppt at this point indicates presence of significant amt of gum. Slight ppt should not be considered positive test for gums, as spices

present in most mayonnaises and french dressings usually give such ppt.) Confirm presence of gums as follows:

Add 35 mL hot  $\text{H}_2\text{O}$  to ppt in bottle, transfer to small beaker, add 5 mL HCl, and boil gently 2 min to hydrolyze gums to sugars. This soln may now be used for various qual. tests for monosaccharide sugars, as follows:

(a) *Copper reduction test.*—Transfer 1 mL hydrolyzed gum soln to test tube, neutze to litmus paper with ca 2N NaOH, and remove paper. Add 5 mL Benedict qual. soln, 16.269(a), and boil vigorously 1–2 min. Let cool spontaneously. Voluminous ppt, which may be green, yellow, or red, indicates reducing sugars.

(b) *Molisch test.*—Transfer 5 mL hydrolyzed gum soln to test tube, and add 2 drops 15% alc.  $\alpha$ -naphthol soln. Incline tube and slowly pour 3–5 mL  $\text{H}_2\text{SO}_4$  down inner side so that 2 layers do not mix. Reddish-violet zone at point of contact indicates carbohydrates. (5% alc. thymol soln may be substituted for  $\alpha$ -naphthol.)

### Gums in Salad Dressing (14)—Official Final Action

(Applicable in presence of starch)

#### 30.055

#### Reagents

(a) *Calcium chloride soln.*—Sp gr 1.2 at  $20^\circ$ . If cloudy, let soln stand so insol. matter may ppt, and then filter.

(b) *Iodine soln.*—See 30.040(c).

#### 30.056

#### Separation of Gums from Starch

Defat 50 g salad dressing by heating on steam bath in 250 mL beaker until fat seps, cool, and ext with pet ether until last ether ext is colorless. Make alk. with  $\text{MgCO}_3$  (2–2.5 g), testing with pH test paper. Heat mixt. in  $\text{H}_2\text{O}$  bath at  $80^\circ$  until residual ether and  $\text{CO}_2$  are expelled. Add 100 mL  $\text{CaCl}_2$  soln and heat in boiling  $\text{H}_2\text{O}$  bath 30 min, stirring occasionally. Pour into 250 mL Pyrex centr. bottle, centr., and decant as much of supernate as possible into 250 mL separator. Add 10 mL  $\text{CaCl}_2$  soln to residue in bottle and shake well. Centr. and decant supernate as before into separator. Swirl funnel gently and let oil sep. Drain all material below oil into another 250 mL Pyrex centr. bottle. Centr. and filter supernate thru 11 cm buchner fitted with Whatman No. 1, or equiv., paper precoated with layer of Celite filter-aid, or equiv. Collect filtrate in beaker within bell jar or in large test tube in suction flask. Add 10 mL  $\text{CaCl}_2$  soln to residue in centr. bottle, shake well, centr., and decant supernate onto filter in buchner. Wash filter with enough  $\text{CaCl}_2$  soln to make total vol. filtrate ca 110 mL.

Add slowly, with stirring, 20 mL I soln to clear ext to ppt starch-iodide. I should be present in considerable excess over amt required to react quant. with the starch. Considerable amts of reducing substances are present, which must be satisfied before starch can be quant. sepd. Add small amt of Celite filter-aid and let starch-iodide, which seps in finely divided condition, stand ca 1 hr. Filter by suction thru 11 cm Whatman No. 1, or equiv., paper, precoated with adequate layer of Celite. Use wire screen under paper to aid filtration. Do not wash pad. Test for excess I in filtrate with starch-iodide paper or starch soln. This test must be pos. to ensure removal of all starch. Add 4 vols alcohol to brown filtrate, and let stand overnight.

Centr. off pptd crude gum. Wash twice with 70% alcohol. If possible, gum should be transferred to centr. bottle, but in some cases gum adheres so firmly to wall of beaker that it can only be rinsed until washings are clear.

Heat on steam bath or in oven at  $100^\circ$  until alcohol is removed. Dissolve residue in 20 mL  $\text{H}_2\text{O}$  by heating in  $\text{H}_2\text{O}$  bath until no more material dissolves. Use rubber policeman to assist soln. (Be sure gum is dissolved or it will be lost here.) Centr. to

remove any insol. material. Decant supernate into another 250 mL centr. bottle; add 1 drop HOAc and 1 drop  $\text{CaCl}_2$  soln; and reppt with 4 vols alcohol. Let stand  $\geq 1$  hr or overnight. Centrf. and wash ppt twice with 70% alcohol by shaking well and centrfg.

Again evap. alcohol with aid of gentle air stream by heating in hot  $\text{H}_2\text{O}$  bath and dissolve ppt in 10 mL hot  $\text{H}_2\text{O}$ , using rubber policeman. (Heed warning in preceding par.) Centrf. to remove any insol. material and decant into 50 mL heavy duty Pyrex centr. tube. (Short cone type is less likely to break.) Adjust vol. to 10 mL, add 1 drop HOAc and 1 drop  $\text{CaCl}_2$  soln, and reppt with 40 mL alcohol. Let stand 1 hr, centrfg., and wash with 70% alcohol as before. Heavy flocculent ppt at this point indicates presence of gums. Disregard very small amt of ppt adhering to walls of centr. tube or appearing as mere turbidity, as spice gums present in most salad dressing usually give such ppt.

**30.057****Detection of Gum**

To confirm presence of gums, remove residual alcohol by gentle heating in hot  $\text{H}_2\text{O}$  bath, dissolve residue in 10 mL hot  $\text{H}_2\text{O}$ , and centrfg. to remove any insol. material. Decant supernate into 10 mL graduate, dil. to 10 mL with  $\text{H}_2\text{O}$ , and mix. To 1 mL of this soln add 1 or 2 drops basic  $\text{Pb}(\text{OAc})_2$  reagent, **31.021(a)**, 1 drop at time. Immediate flocculent, curdy, or gelatinous ppt is confirmation of presence of gums. Ppt may form on standing but this is to be disregarded.

**Alginates (15)—Official First Action**

(Applicable to mayonnaise, salad dressing, and french dressing)

**30.058****Preparation of Sample**

Weigh, directly into 250 mL centr. bottle, 2 g or enough sample to give 10–20 mg alginate (ca 2 g at 0.5% level). Disperse in 50 mL  $\text{H}_2\text{O}$  and fill bottle with acetone-alcohol (1+2). Shake vigorously and let stand until ppt begins to settle; then centrfg. ca 10 min at 1600–1700 rpm. Decant, discard liq., disperse ppt in 50 mL  $\text{H}_2\text{O}$ , and reppt 2 more times. To ppt add 50 mL *dioxane*, shake well, and filter thru asbestos-matted gooch with suction. Transfer ppt to gooch, rinse bottle and ppt with several portions *dioxane*, and suck dry. Return ppt and asbestos mat to centr. bottle, add 50 mL  $\text{H}_2\text{O}$ , disperse ppt, and adjust to pH 8–9 with 3% NaOH. (With french dressing add 0.25 g Celite 545, shake, and let stand 10 min, shaking several times. Centrf. 10 min at 1600–1700 rpm. Decant supernate, filtering if necessary to remove suspended particles.) To 10 mL aliquot in 50 mL centr. tube, add 40 mL acetone-alcohol (1+2), stir vigorously, and let stand until ppt forms. If necessary, add 1 drop satd NaCl soln to start pptn. Centrf., discard liq., and dry ppt on steam bath.

**30.059****Detection**

(Start detection at beginning of day so color changes can be observed.)

Moisten ppt with 3 drops 0.1N NaOH, rubbing thoroly with glass rod. Add 2 mL  $\text{Fe-H}_2\text{SO}_4$  reagent, **13.058**, and let stand. Formation of purple-red color indicates presence of alginate. If brown color forms, repeat detection, using smaller aliquot for final pptn. Alginates are absent if no color develops on standing overnight.

**Starch—Official Final Action****30.060****Reagents**

See **30.040**.

**30.061****Determination**

Det. total acidity of prepd sample as in **30.049**. Place 4–5 g prepd sample in 500 mL erlenmeyer and add calcd vol. 0.1N NaOH, *V*, to neutze acid in wt sample taken. Pipet in 100 mL  $\text{CaCl}_2$  soln, stopper flask, and swirl gently until all large lumps of dressing are broken up. Continue as in **30.041**, par. 1, beginning "Add glass beads." Calc. % starch from formula:

% Starch =  $[\text{g glucose} \times 0.925(100 + V + W) \times 8] / \text{wt sample}$ , where *W* = g  $\text{H}_2\text{O}$  in sample taken (calcd from solids, **30.045**.)

**VINEGARS (16)**

(Unless otherwise directed, express results as g/100 mL.)

**30.062 Organoleptic Examination—Procedure**

Note appearance, color, odor, and taste. Neutze portion of sample with NaOH soln and note odor and taste. Ext neutzd vinegar with ether, evap. ether ext, and note odor and taste of residue. (Spices and pungent materials are indicated by characteristic odors and tastes.) Evap. portion of sample on  $\text{H}_2\text{O}$  bath. Odor of material as last of volatile matter evaps and appearance and taste of residue give information as to source and character of vinegar.

**30.063 Preparation of Sample—Procedure**

Mix thoroly and filter thru rapid paper.

**30.064 Solids—Official Final Action**

Measure 10 mL sample into weighed 50 mm diam., flat-bottom Pt dish, evap. on boiling  $\text{H}_2\text{O}$  bath 30 min, and dry exactly 2.5 hr in oven at temp. of boiling  $\text{H}_2\text{O}$ . Cool in desiccator and weigh. (To obtain concordant results it is necessary to use dish of size and shape stated and to dry exactly time specified.)

**30.065 Ash—Official Final Action**

Measure 25 mL sample into weighed Pt dish, evap. to dryness on  $\text{H}_2\text{O}$  or steam bath, and heat in furnace 30 min at 500–550°. Break up charred mass in Pt dish, add hot  $\text{H}_2\text{O}$ , filter thru ashless paper, and wash *thoroly* with  $\text{H}_2\text{O}$ . Return paper and contents to dish, dry, and heat 30 min at ca 525°, or until all C is burned off. Add filtrate, evap. to dryness, and heat 15 min at ca 525°. Cool in desiccator and weigh (wt *x*). Reheat 5 min at ca 525°, and cool  $\leq 1$  hr in desiccator contg efficient desiccant. Put 1 or 2 dishes (preferably only 1) in desiccator at a time. Place wt *x* on balance pan before removing dish from desiccator, and weigh rapidly to nearest mg. Calc. total ash from last wt.

**30.066 Soluble and Insoluble Ash—Official Final Action**

Treat ash, **30.065**, as in **31.015**.

**30.067 Alkalinity of Soluble Ash—Official Final Action**

Proceed as in **31.016**, using sol. ash obtained in **30.066**. Express result as number mL 1N acid required to neutze sol. ash from 100 mL vinegar. If relationship of ash to alky of sol. ash is abnormal, study composition of ash, especially content of chlorides, sulfates, phosphates, and alkalies (J. Amer. Chem. Soc. **22**, 218(1900)).

**30.068 Soluble Phosphorus (17)—Official Final Action**

Proceed as in **7.119**, or **8.033**, or **22.041**★, using soln obtained in **30.067**. If either volumetric or colorimetric method is used, stdze with sample of known phosphate content. Express results as mg  $\text{P}_2\text{O}_5$ /100 mL vinegar.

**30.069 Insoluble Phosphorus (17)—Official Final Action**

Dissolve  $\text{H}_2\text{O}$ -insol. ash, **30.066**, in ca 50 mL boiling  $\text{HNO}_3$  (1+8) (use 25 mL  $\text{H}_2\text{SO}_4$  (1+9) for colorimetric method) and proceed as in **7.119**, or **8.033**, or **22.041**★. If either volumetric or colorimetric method is used, stdze with sample of known phosphate content. Express result as mg  $\text{P}_2\text{O}_5$ /100 mL vinegar.

**30.070 Total Phosphorus (17)—Official Final Action**

Dissolve ash, **30.065**, or both sol. and insol. ash, **30.066**, in ca 50 mL boiling  $\text{HNO}_3$  (1+8) (use 25 mL  $\text{H}_2\text{SO}_4$  (1+9) for colorimetric method) and proceed as in **7.119**, or **8.033**, or **22.041**★. If either volumetric or colorimetric method is used, stdze with sample of known phosphate content. Express result as mg  $\text{P}_2\text{O}_5$ /100 mL vinegar. If desired, digest vinegar as in **22.041**★, instead of using ash from **30.065**.

**30.071 Total Acids—Official Final Action**

Dil. 10 mL sample with recently boiled and cooled  $\text{H}_2\text{O}$  until it appears only slightly colored and titr. with 0.5*N* alkali, using phthln. 1 mL 0.5*N* alkali = 0.0300 g HOAc.

**30.072 Nonvolatile Acids—Official Final Action**

Measure 10 mL vinegar into 200 mL porcelain casserole, evap. just to dryness, add 5–10 mL  $\text{H}_2\text{O}$ , and again evap.; repeat until  $\geq 5$  evapns have been made. Add ca 200 mL recently boiled and cooled  $\text{H}_2\text{O}$ , and titr. with 0.1*N* alkali, using phthln. 1 mL 0.1*N* alkali = 0.00600 g HOAc.

**30.073 Volatile Acids—Official Final Action**

Subtract nonvolatile acids, **30.072**, from total acids, **30.071**.

**30.074 Total Reducing Substances Before Inversion  
Official Final Action**

Measure 25 mL sample into 50 mL vol. flask and add enough NaOH soln (1+1) to nearly neutze acid. Cool, dil. to vol. with  $\text{H}_2\text{O}$ , and det. reducing substances in 20 mL soln as in **31.038**. If amt of reducing substances is very small, use 40 mL. Calc. result as invert sugar (for malt vinegar as glucose).

**30.075 Total Reducing Substances After Inversion  
Official Final Action**

Invert 25 mL sample in 50 mL vol. flask with 5 mL HCl, as in **31.026(b)** or (c). Nearly neutze with NaOH soln (1+1) and det. reducing substances as in **31.038**.

**30.076 Nonvolatile Reducing Substances (Sugar)  
Official Final Action**

(Useful in calcd nonsugar solids)

Evap. 50 mL sample on steam or  $\text{H}_2\text{O}$  bath to sirupy consistency, add 10 mL  $\text{H}_2\text{O}$ , and evap. again. Repeat with 10 mL  $\text{H}_2\text{O}$ . Transfer residue to 100 mL vol. flask with ca 50 mL warm  $\text{H}_2\text{O}$ . Cool, invert with 10 mL HCl as in **31.026(b)** or (c), and nearly neutze with NaOH soln (1+1). Cool, dil. to vol. with  $\text{H}_2\text{O}$ , and det. reducing substances in 20 mL or 40 mL, depending on amt present, as in **31.038**. Calc. result as invert sugar (for malt vinegar as glucose). If results for total reducing substances before and after inversion show absence of sucrose, inversion may be omitted here.

**30.077 Volatile Reducing Substances (18)—Procedure**

When sucrose is absent, subtract amt of nonvolatile reducing substances, **30.076**, from mean of total reducing substances

before inversion, **30.074**, and after inversion, **30.075**. When sucrose is present, subtract amt of nonvolatile reducing substances, **30.076**, from amt of total reducing substances after inversion, **30.075**.

**30.078 Alcohol—Official Final Action**

Measure 100 mL sample into r-b distn flask. Make faintly alk. with NaOH soln (1+1), distil almost 50 mL, dil. to 50 mL at temp. of sample, and det. sp gr at 20/20° with pycnometer, **9.011**. Obtain % by vol. from **52.003**. Undue foaming may be avoided by adding small piece of paraffin, free from volatile constituents.

**30.079 ★ Glycerol (19)—Official Final Action ★**

All oxidizable org. material except glycerol is removed by evapn, pptn with  $\text{Ca}(\text{OH})_2$  and alcohol, absolute alcohol and ether,  $\text{Ag}_2\text{CO}_3$ , and basic  $\text{Pb}(\text{OAc})_2$ . Residual glycerol is oxidized with dichromate in acid soln, and the excess is titrd with  $\text{Fe}^{+2}$ . See **30.079–30.080**, 12th ed.

**30.080 Color—Official Final Action**

Det. depth of color in Lovibond tintometer by good reflected daylight, using  $\frac{1}{2}$  or 1" cell and brewer's scale. Report result in terms of  $\frac{1}{2}$ " cell and so state.

**30.081 Polarization (20)—Official Final Action**

Whenever possible, polarize in 200 mm tube without decolorizing. Report result on basis of 200 mm tube in °S, **31.020(a)**. When necessary, decolorize as follows:

(a) To 50 mL sample add measured vol. of satd neut.  $\text{Pb}(\text{OAc})_2$  soln, avoiding excess of Pb; filter, remove Pb with powd anhyd. K oxalate, and filter. Polarize and correct for diln with  $\text{Pb}(\text{OAc})_2$  soln.

(b) To 50 mL sample add decolorizing C, avoiding excess or too long treatment. Filter thru double paper and polarize.

**30.082 Sulfates—Official Final Action**

To 100 mL sample add 2 mL ca 1*N* HCl, heat to bp, and add 10 mL hot  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  soln (1 g/100 mL), dropwise. Continue boiling 5 min, keeping vol. ca const by adding hot  $\text{H}_2\text{O}$  as required. Let mixt. stand until supernate is clear (overnight is convenient, but this time should not be exceeded). Filter on ashless paper or weighed Munroe crucible (Z. Anal. Chem. **2**, 241(1888); J. Amer. Chem. Soc. **31**, 456, 928(1909)). Wash Cl-free with hot  $\text{H}_2\text{O}$ , dry, ignite at red heat (700–800°), cool, and weigh. Express result as mg  $\text{SO}_3$ /100 mL vinegar.

**30.083 Dextrin (Qualitative Test)—Procedure**

Evap. 100 mL sample to ca 15 mL. Slowly add 200 mL alcohol, with const stirring, and let stand overnight. Sep. ppt, preferably by centrfg, and wash with 80% alcohol. Dissolve in min. vol.  $\text{H}_2\text{O}$  and det. optical rotation. Distinct optical rotation indicates dextrin. Treat soln with several drops l soln of ca same color intensity. Formation of reddish brown color indicates dextrin.

**30.084 Preservatives**

See Chap. 20.

**Permanganate Oxidation Number (21)  
Official Final Action**

(For differentiating between vinegar and com. HOAc)

★ Surplus method—see inside front cover.

## 30.085

**Reagents**

(a) *Potassium permanganate soln.*—31 g/L. Prep. according to 50.025; stdzn is unnecessary.

(b) *Sodium thiosulfate soln.*—0.5*N*. Accurately stdze against  $K_2Cr_2O_7$  as in 50.038, except use ca 0.5 g  $K_2Cr_2O_7$ , 10 g KI, 10 mL HCl, and 90 mL  $H_2O$ .

(c) *Potassium iodide soln.*—Dissolve 50 g KI in 100 mL  $H_2O$  and filter. Do not use unless colorless.

## 30.086

**Determination**

Adjust sample to 4 g/100 mL acidity as HOAc. Steam distil 50 mL adjusted sample and collect 50 mL distillate. Regulate distn so that ca 45 mL remains in distg flask when 50 mL distillate has been collected. All-glass app. is preferable; if not available, cover cork or rubber stoppers with Sn or Al foil. App. illustrated in Fig. 18.02, 18.050(a), is convenient. Keep distillate and reagents at 25°.

Transfer 50 mL distillate to 500 mL g-s erlenmeyer. Add 10 mL  $H_2SO_4$  (1+1) and 25 mL  $KMnO_4$  soln. Accurately measure  $KMnO_4$  soln, draining pipet definite time. Hold at 25°, preferably in  $H_2O$  bath, exactly 1 hr. Then immediately add 20 mL KI soln and mix well. Tit. liberated I with 0.5*N*  $Na_2S_2O_3$ .

Conduct blank detn at same time, using 50 mL  $H_2O$ , 10 mL  $H_2SO_4$  (1+1), and 25 mL  $KMnO_4$  soln.

(mL 0.5*N*  $Na_2S_2O_3$  required by blank – mL used in detn)/2 = permanganate oxidn number of vinegar. Report on basis of adjusted vinegar (4% acid).

If permanganate oxidn number is >15, repeat detn, using 25 mL adjusted vinegar + 25 mL  $H_2O$ . Repeat this reduction by ½ until mL  $KMnO_4$  soln used is <15. Calc. permanganate oxidn number to basis of 50 mL adjusted vinegar.

# 31. Sugars and Sugar Products

## SUGARS AND SIRUPS

### 31.001 Preparation of Sample—Official Final Action

(a) *Solids (sugars, etc.)*.—Grind, if necessary, and mix to uniformity. Thoroughly mix raw sugars with spatula in min. time. Break up any lumps either on glass plate with glass or iron rolling pin, or in large, clean, dry mortar, with pestle.

(b) *Semisolids (massecuites, etc.)*.—Weigh 50 g sample, dissolve crystals of sugar in min. vol. of H<sub>2</sub>O, wash into 250 mL vol. flask, dil. to vol., and mix thoroughly; or weigh 50 g sample and dil. with H<sub>2</sub>O to 100 g. If insol. material remains, mix uniformly by shaking before taking aliquots or weighed portions for detns.

(c) *Liquids (molasses, sirups, etc.)*.—Mix materials thoroughly. If crystals of sugar are present, dissolve them by heating gently (avoiding loss of H<sub>2</sub>O by evapn), or by weighing whole mass, then adding H<sub>2</sub>O, heating until completely dissolved, and after cooling, reweighing. Calc. all results to wt original substance.

### Color of Raw Cane Sugars (7)—Official First Action

#### 31.002

#### Reagent

*Filter-aid.*—Celite, or equiv., analytical filter-aid.

#### 31.003

#### Apparatus

*Fractionator.*—Construct fractionator of 35 mm id, heavy-wall Pyrex tubing, 145 mm long from top to bottom shoulder where it is sealed to  $\frac{3}{8}$  stopcock with 3 mm bore and 9 mm od tubing. Leave 55 mm stem below stopcock. Seal tube, 9 mm od, 45 mm long, to body of fractionator 45 mm below top. Connect to buchner and source of vac. thru "T" tube as shown in Fig. 31.01. (Dimensions are not critical.)

#### 31.004

#### Determination

Place 60 g sample in flask, add 40 g boiling H<sub>2</sub>O, and rotate flask until all sugar dissolves. Add 3 g Celite and shake mixt. vigorously 1 min. Assemble special filtration app., and connect to const vac. of 610 mm (81.3 kPa; 24"). With stopcock open, place paper, S&S 589 blue ribbon, 7 cm diam., in buchner, wet with H<sub>2</sub>O, and suck excess H<sub>2</sub>O thru filtering tube into flask. Close stopcock and pour well-shaken mixt. of sugar soln and Celite evenly over paper. Collect ca 10 mL of first filtrate, which is somewhat turbid, in filtering tube and run into flask by opening stopcock. Close stopcock, collect another 10 mL filtrate in filtering tube, and run into flask as before to wash inner walls of tube free from any small particles of turbidity. Keep bed of Celite well covered with sugar soln during entire filtration. *Do not let it run dry.* Collect final clear filtrate in filtering tube, transfer to small bottle or to small, g-s erlenmeyer, and mix thoroughly. Det. refractometer Brix on portion of soln and calc. concn,  $c$  (g dry substance/mL soln), by multiplying Brix by corresponding true density and dividing by 100.

Det. %  $T$  at 560 nm on spectrophtr with wavelength and  $T$  scales that have been checked, preferably with std glass filter supplied by NBS. Use distd H<sub>2</sub>O as the 100%  $T$  std. Cell thickness,  $b$  (in cm), used should be such that readings are within range 25–75%  $T$ .

Calc. attenuation index,  $a_c^* = -(\log T)/bc$ .

## Moisture

### 31.005 Vacuum Drying—Official Final Action

(Applicable to cane and beet, raw and refined sugars)

Dry 2–5 g prepd sample, 31.001(a), in flat dish (Ni, Pt, or Al with tight-fit cover), 2 hr at  $\leq 70^\circ$  (preferably  $60^\circ$ ), under pressure  $\leq 50$  mm Hg (6.7 kPa). Bleed oven with current of air (dried by passing thru anhyd. CaSO<sub>4</sub>, P<sub>2</sub>O<sub>5</sub>, or other efficient desiccant) during drying to remove H<sub>2</sub>O vapor. Remove dish from oven, cover, cool in desiccator, and weigh. Redry 1 hr and repeat process until change in wt between successive dryings at 1 hr intervals is  $\leq 2$  mg.

### 31.006 Drying at Atmospheric Pressure—Procedure

(Applicable to cane and beet, raw and refined sugars)

Dry ca 5 g prepd sample, 31.001(a), in flat dish (Ni, Pt, or Al with tight-fit cover), 3 hr at  $100^\circ$ . Remove dish, cover, cool in desiccator, and weigh. Redry 1 hr and repeat process until change in wt between successive dryings at 1 hr intervals is  $\leq 2$

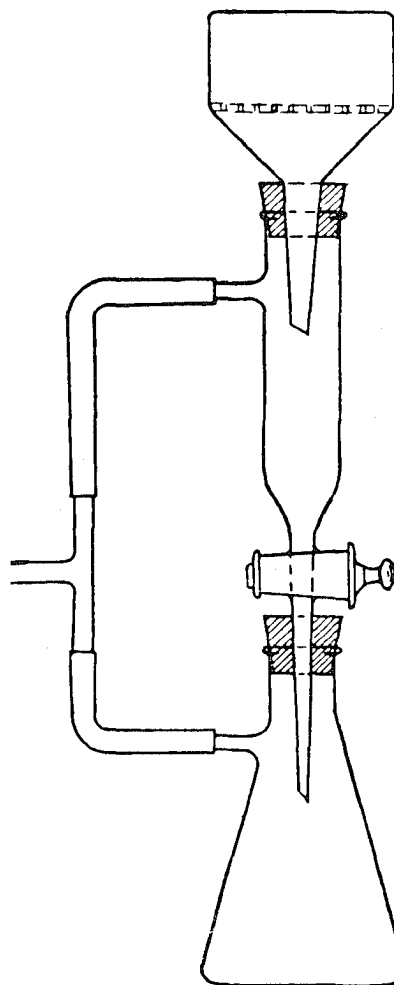

FIG. 31.01—Fractionator

mg. For large-grain sugars, increase temp. to 105–110° in final heating periods to expel last traces of occluded H<sub>2</sub>O. Report loss in wt as H<sub>2</sub>O.

### 31.007 *Drying upon Pumice Stone—Official Final Action*

(Applicable to massecuites, molasses, and other liq. and semiliq. products)

Prep. pumice stone of 2 grades of fineness, one to pass thru 1 mm sieve, other thru 6 mm but not 1 mm sieve. Digest each 8 hr with H<sub>2</sub>SO<sub>4</sub> (1+4) on steam bath. Wash acid-free and heat to 525°. Make detn in flat metal dish 60 mm diam. Place 3 mm layer of the fine pumice stone on bottom of dish, then 6–10 mm layer of coarse pumice stone; dry and weigh. Dil. sample with weighed portion of H<sub>2</sub>O so that dild material contains 20–30% solid matter. Weigh, into prepd dish, amt of dild sample to yield ca 1 g dry matter. If this weighing cannot be made rapidly, use weighing bottle provided with cork thru which pipet passes. Dry at 70° under pressure ≤50 mm Hg (6.7 kPa), bleeding with dry air as in 31.005. Make trial weighings at 2 hr intervals toward end of drying period until change in wt is ≤2 mg. Report loss in wt as H<sub>2</sub>O. Substances contg little or no fructose or other readily decomposable substance may be dried in oven at 100°.

### 31.008 *Drying upon Quartz Sand (2)—Official Final Action*

(Applicable to massecuites, molasses, and other liq. and semiliq. products)

Digest pure quartz sand that passes No. 40 but not No. 60 sieve with HCl, wash acid-free, dry, and ignite. Preserve in stoppered bottle. Place 25–30 g prepd sand and short stirring rod in dish ca 55 mm diam. and 40 mm deep, fitted with cover. Dry thoroly, cover dish, cool in desiccator, and weigh immediately. Add enough dild sample of known wt to yield ca 1 g dry matter and mix thoroly with sand. Heat on steam bath 15–20 min, stirring at 2–3 min intervals, or until mass becomes too stiff to manipulate readily. Dry at <70° (preferably 60°) under pressure ≤50 mm Hg (6.7 kPa), bleeding with dry air as in 31.005. Make trial weighings at 2 hr intervals toward end of drying period (ca 18 hr) until change in wt is ≤2 mg.

For materials contg no fructose or other readily decomposable substance, dry 8–10 hr at atm. pressure in oven at 100°, cool in desiccator, and weigh, repeating heating and weighing until loss in 1 hr heating is ≤2 mg. Report loss in wt as H<sub>2</sub>O.

As dry sand, as well as dried sample, absorbs appreciable moisture on standing over most desiccating agents, make all weighings as quickly as possible after cooling in desiccator.

## Solids

### 31.009 *By Means of Spindle—Official Final Action*

(Accurate only when applied to pure sucrose solns, but extensively used for approx. results with liq. sugar products contg invert sugar and other nonsucrose solids)

(a) *Direct*.—Density of juices, sirups, etc., is conveniently detd with Brix or Baumé hydrometer, preferably former as scale graduations agree closely with % total solids. Table for comparison of degrees Brix (% by wt of pure sucrose in pure solns), degrees Baumé (modulus 145), sp gr at 20/4°, and sp gr at 20/20° is given in 52.008.

Use Brix spindle graduated in tenths and of appropriate range, and cylinder of sufficient diam. (≥12 mm larger than spindle bulb) to permit spindle to come to rest without touching sides. Soln should be at room temp. If this varies >1° from temp. at which spindle was graduated (20°), apply correction according to 52.010. Before taking reading, let soln stand in cylinder until all air bubbles escape and all fatty or waxy materials come to

top and are skimmed off. (Air bubbles may be conveniently removed by applying vac. to cylinder by means of tube passing thru stopper inserted in top of cylinder.) Lower spindle slowly into sirup; do not let sirup on spindle reach above sirup level.

(b) *Double dilution*.—If sample is too dense to det. density directly, dil. weighed portion with weighed amt of H<sub>2</sub>O, or dissolve weighed portion and dil. to known vol. with H<sub>2</sub>O. In first instance, % total solids is calcd by following formula:

$$\% \text{ Solids in undild material} = WS/w,$$

where  $S$  = % solids in dild material;  $W$  = wt dild material; and  $w$  = wt sample taken for diln.

When diln is made to definite vol., use following formula:

$$\% \text{ Solids in undild material} = VDS/w,$$

where  $V$  = vol. dild soln at given temp.;  $D$  = sp gr of dild soln at same temp.;  $S$  = % solids in dild soln at same temp.; and  $w$  = wt sample taken for diln.

Calcn is simplified by mixing equal wts sugar product and H<sub>2</sub>O, and multiplying Brix of soln by 2.

### 31.010 *By Means of Pycnometer (3)—Official Final Action*

(a) *Specific gravity (in vacuo or in air)*.—Det. sp gr of soln at 20/4°, 20/20° *in vacuo*, or 20/20° in air as in 9.011, using either pycnometers described in 9.009(b) or other suitable type. Det. % by wt of solids as sucrose from appropriate table, 52.008 or 52.020. When density of substance is too high for direct detn, dil. and then calc. sucrose content of original material as in 31.009(b).

(b) *Specific gravity of molasses*.—Use special calibrated 100 mL vol. flask with neck ca 8 mm id. Weigh empty flask and then fill with molasses, using long-stem funnel reaching below graduation mark, until level of molasses is up to lower end of neck of flask. (Flow of molasses may be stopped by inserting glass rod of suitable size into funnel so as to close stem opening.) Carefully remove funnel to prevent molasses from coming in contact with neck, and weigh flask and molasses. Add H<sub>2</sub>O almost to graduation mark, running it down side of neck to prevent mixing with molasses. Let stand several hr or overnight for bubbles to escape. Place flask in const temp. H<sub>2</sub>O bath, preferably at 20°, and leave until it reaches bath temp. Dil. to vol. at that temp. with H<sub>2</sub>O. Weigh. Reduce wt molasses to *in vacuo* and calc. density. Obtain corresponding Brix or Baumé reading from 52.008.

*Example:*

	grams
X, wt H <sub>2</sub> O content of flask at 20° <i>in vacuo</i>	= 99.823
Y, wt molasses at 20° <i>in vacuo</i>	= 132.834
Z, wt molasses and H <sub>2</sub> O at 20° <i>in vacuo</i>	= 137.968
X – (Z – Y) = wt H <sub>2</sub> O occupying space of molasses <i>in vacuo</i>	= 94.689

$$\frac{132.834}{94.689} = 1.403 \text{ sp gr } \left( \frac{20^\circ}{20^\circ} \right) \text{ molasses.}$$

### 31.011 *By Means of Refractometer (4) Official Final Action*

(Applicable only to liq. samples contg no undissolved solids)

Sol. solids by refractometric method is that concn by wt of sucrose in soln that has same  $n$  as soln analyzed. Use instrument with scale graduated at least in 0.001 units or 0.5% sucrose, permitting estn to 0.0002 $n$  or 0.25%, resp. Adjust instrument to read  $n$  of 1.3330 or 0% sucrose with H<sub>2</sub>O at 20°.

Det. refractometer reading of soln at 20° and obtain corresponding % dry substance from either direct reading, if sugar refractometer is used, or from 52.012, if instrument gives

readings in terms of refractive index. Circulate  $H_2O$  at const temp., preferably  $20^\circ$ , thru jackets of refractometer or thru trough of immersion instrument, long enough to let temp. of prisms and of sample reach equilibrium, continuing circulation during observations and taking care that temp. is held const.

If detn is made at temp. other than  $20^\circ$ , or if humidity causes condensation of moisture on exposed faces of prisms, make measurements at room temp. and correct readings to std temp. of  $20^\circ$  from **52.016**. If soln is too dark to be read in instrument, dil. with concd sugar soln; never use  $H_2O$  for this purpose. Mix weighed amts of soln under examination and soln of pure sugar of about same strength, and calc. % dry substance in former =  $[(W + B)C - BD]/W$ , where  $W$  = wt (g) sample mixed with  $B$ ;  $B$  = wt (g) sugar soln used in diln;  $C$  = % dry substance in mixt.  $W + B$  obtained from refractive index; and  $D$  = % dry substance in pure sugar soln obtained from its refractive index.

For liq. products contg invert sugar, correct % solids obtained from **52.012** by adding 0.022 for each % invert sugar in sample.

#### Ash—Official Final Action

##### 31.012 Method I

Heat sample of appropriate wt for product being examined (usually 5–10 g) in 50–100 mL Pt dish at  $100^\circ$  until  $H_2O$  is expelled; add few drops pure olive oil and heat slowly over flame or under IR lamp until swelling stops. Place dish in furnace at ca  $525^\circ$  and leave until white ash is obtained. Moisten ash with  $H_2O$ , dry on steam bath and then on hot plate, and re-ash at  $525^\circ$  to const wt.

##### 31.013 Method II

Carbonize sample of appropriate wt for product being examined (usually 5–10 g) in 50–100 mL Pt dish at ca  $525^\circ$  and treat charred mass with hot  $H_2O$  to dissolve sol. salts. (In case of low-purity products, addn of few drops pure olive oil, as in **31.012**, may be desirable.) Filter thru ashless paper, ignite paper and residue to white ash, add filtrate of sol. salts, evap. to dryness, and ignite at ca  $525^\circ$  to const wt.

##### 31.014 Sulfated Ash—Official Final Action

Weigh 5 g sample into 50–100 mL Pt dish, add 5 mL 10% (by wt)  $H_2SO_4$ , heat on hot plate until sample is well carbonized, and then ash in furnace at ca  $550^\circ$ . Cool, add 2–3 mL 10%  $H_2SO_4$ , evap. on steam bath, dry on hot plate, and again ignite at  $550^\circ$  to const wt. Express result as % sulfated ash.

##### 31.015 Soluble and Insoluble Ash—Official Final Action

Ash sample as in **31.012** or **31.013**. Add 10 mL  $H_2O$  to ash in the Pt dish, heat nearly to boiling, filter thru ashless paper, and wash with hot  $H_2O$  until combined filtrate and washings measure ca 60 mL. Return paper and contents to Pt dish, ignite carefully, cool, and weigh. Calc. %  $H_2O$ -sol. and  $H_2O$ -insol. ash.

##### 31.016 Alkalinity of Soluble Ash—Official Final Action

Cool filtrate from **31.015** and titr. with 0.1N HCl, **50.011–50.012**, using Me orange, **6.005(g)**. Express alky in terms of mL 1N acid/100 g sample.

##### 31.017 Alkalinity of Insoluble Ash—Official Final Action

Add excess 0.1N HCl (usually 10–15 mL) to ignited insol. ash in Pt dish, **31.015**, heat to incipient boiling on hot plate, and cool. Transfer quant. to erlenmeyer and titr. excess HCl with 0.1N NaOH, using Me orange. Express alky in terms of mL 1N acid/100 g sample.

##### 31.018 Mineral Adulterants in Ash (5) Official First Action

In large porcelain evapg dish, mix 100 g sample with ca 35 g  $H_2SO_4$  and evap. to sirupy consistency. Pass elec. current thru it while stirring by placing one Pt electrode in bottom of dish near one side and attaching other to lower end of glass rod with which contents are stirred. Begin with current of ca 1 amp and gradually increase to 4. In 10–15 min mass is reduced to fine, dry char that may be readily burned to white ash in original dish over free flame or in furnace.

*Note:* This method is preferred to ordinary method of heating with  $H_2SO_4$ , especially in case of molasses, because, if properly manipulated, material comes quickly into form of very finely divided char or powder that is especially adapted for subsequent quick ignition.

If elec. current is not available, treat 100 g sample in large porcelain dish, evap. to sirupy consistency with enough  $H_2SO_4$  to carbonize mass thoroly, and ignite in usual manner.

Following adulterants may be present: salts of Sn, used in molasses to bleach; mineral pigments, such as  $PbCrO_4$  in yellow confectionery; oxides of Fe, sometimes used to simulate color of chocolate; and Cu. These elements may be detected by usual qual. tests.

##### 31.019 Nitrogen—Official Final Action

Det. N in 5 g sample as in **2.057**, using larger vol. of the  $H_2SO_4$ , if necessary for complete digestion.

#### Sucrose—Polarimetric Methods

##### 31.020 General Procedure—Official Final Action

(Rules of International Commission for Uniform Methods of Sugar Analysis (ICUMSA) (6))

(a) *Standardization of Saccharimeter Scale.*—Saccharimeter scale must be graduated in conformity with International Sugar Scale adopted by ICUMSA. Rotations on this scale are designated as degrees sugar ( $^\circ S$ ).

Basis of calibration of  $100^\circ$  point on International Sugar Scale is polarization of normal soln of pure sucrose (26.000 g/100 mL) at  $20^\circ$  in 200 mm tube, using white light and dichromate filter defined by Commission, (b). This soln, polarized at  $20^\circ$ , must give saccharimeter reading of exactly  $100^\circ S$ . Temp. of sugar soln during polarization must be kept constant at  $20^\circ$ .

Following rotations hold for normal quartz plate of International Sugar Scale: Normal Quartz Plate =  $100^\circ S = 40.690^\circ \pm 0.002^\circ$  ( $\lambda = 5461 \text{ \AA}$ ) at  $20^\circ$

$$1^\circ (\lambda = 5461 \text{ \AA}) = 2.4576^\circ S$$

Normal Quartz Plate =  $100^\circ S = 34.620^\circ \pm 0.002^\circ$  ( $\lambda = 5892.5 \text{ \AA}$ ) at  $20^\circ$

$$1^\circ (\lambda = 5892.5 \text{ \AA}) = 2.8885^\circ S$$

For existing saccharimeters graduated on Herzfeld-Schönrock scale, either change saccharimeter scale or use wt w of 26.026 g in 100 mL.

(b) *Directions for Raw Sugars.*—In general, make all polarizations at  $20^\circ$ . For countries where mean temp. is  $>20^\circ$ , saccharimeters may be adjusted at  $30^\circ$  or any other suitable temp., under conditions specified above, provided sugar soln is dild to final vol. and polarized at this same temp.

In detg polarization of substances contg sugar, use only half-shade instruments, either single- or double-wedge, and either 200 or 400 mm instruments. During observation, keep app. in fixed position and so far removed from source of light that polarizing nicol is not warmed. As sources of light, use lamps that give strong white illumination or Na lamp. Whenever there

is any irregularity in source of light, place thin ground-glass plate between source of light and polariscope so as to render illumination uniform.

Before and after each set of observations, det. correct adjustment of saccharimeter, using stdzd quartz plates; use calibrated wts, polarization flasks, and observation tubes and cover glasses. (Scratched or strained cover glasses must not be used.) Make several readings and take mean thereof but do not reject any reading.

Quartz plates are stdzd to second decimal place. Instrument and plate must be at same temp. (preferably 20°). Different points of scale, preferably 20°, 50°, 80°, and 100°S, should be tested against the plates.

In detg polarization, use whole normal wt ( $26 \pm 0.002$  g) for 100 mL or multiple for any corresponding vol. Bring soln exactly to mark at proper temp. and after wiping out neck of flask with filter paper, add min. amt of dry basic Pb(OAc)<sub>2</sub>, 31.021(c), shake to dissolve, and pour all clarified sugar soln on rapid, air-dry filter. Cover funnel at start of filtration. Reject first 25 mL filtrate and use remainder (must be perfectly clear) for polarization. In no case return whole soln or any part to filter. If filtrate is cloudy after 25 mL has been rejected, begin new detn. Polarize in 200 mm tube. If, after all means have been used to effect proper decolorization, soln is too dark to read, use 100 mm tube and multiply reading by 2.

Other permissible clarifying and decolorizing agents are alumina cream, 31.021(b), or concd alum soln. Do not use boneblack or decolorizing powders.

Whenever white light is used, it must be filtered thru soln of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> of such concn that % K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> × length of column of soln in cm = 9. Double this concn in polarizing carbohydrate materials of high rotation dispersion, such as com. glucose, etc.

(c) *Normal Weights and Conversion Factors of Different Saccharimeter Scales.*—(1) *Herzfeld-Schönrock Scale.*—Normal wt = 26.026 g/100 mL soln. 1° = 0.34657° Angular Rotation D.\*

(2) *International Sugar Scale.*—Normal wt = 26.000 g/100 mL soln. 1° = 0.34620° Angular Rotation D.\*

(3) *French Sugar Scale.*—Normal wt = 16.269 g/100 mL soln. 1° = 0.21667° Angular Rotation D.\*

### 31.021 Preparation and Use of Clarifying Reagents (7) Official Final Action

(Caution: See 51.084.)

(a) *Basic lead acetate soln.*—Activate litharge by heating 2.5–3 hr at 650–670° in furnace (cooled product should be lemon color). Boil 430 g neut. Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O, 130 g freshly activated litharge, and 1 L H<sub>2</sub>O 30 min. Let mixt. cool and settle; then dil. supernate to sp gr of 1.25 with recently boiled H<sub>2</sub>O. (Solid basic Pb(OAc)<sub>2</sub> may be substituted for the normal salt and litharge in prepn of soln. Because of error caused by vol. of ppt, this reagent is not recommended for clarifying products of low purity.)

(b) *Alumina cream.*—Prep. cold satd soln of alum in H<sub>2</sub>O. Add NH<sub>4</sub>OH with constant stirring until soln is alk. to litmus, let ppt settle, and wash by decantation with H<sub>2</sub>O until wash H<sub>2</sub>O gives only slight test for sulfates with BaCl<sub>2</sub> soln. Pour off excess H<sub>2</sub>O and store residual cream in g-s bottle. (Alumina cream is suitable for clarifying light-colored sugar products or as adjunct to other agents when sugars are detd by polariscopic or reducing sugar methods.)

(c) *Dry basic lead acetate ACS.*—3Pb(OAc)<sub>2</sub>·2PbO. Of this salt, ca 0.3 g = 1 mL basic Pb(OAc)<sub>2</sub> soln, (a). In making clarification,

add small amt of dry salt to sugar soln after dilg to vol., and shake; then add more salt and shake again, repeating addn until pptn is complete, but avoiding any excess. When molasses or any other substance producing heavy ppt is being clarified, add some dry, coarse sand to break up pellets of basic Pb(OAc)<sub>2</sub> and ppt. (Unless in excess, dry basic Pb(OAc)<sub>2</sub> does not cause vol. error.)

(d) *Neutral lead acetate soln.*—Prep. satd soln of neut. Pb(OAc)<sub>2</sub> and add to sugar soln before dilg to vol. (This reagent may be used for clarifying light-colored sugar products when sugars are detd by polariscopic methods, and its use is imperative when reducing sugars are detd in soln used for polarization.)

To remove excess Pb used in clarification, add anhyd. K or Na oxalate to clarified filtrate in small amts until test for Pb in filtrate is neg.; then refilter.

### 31.022 Temperature Corrections for Polarization of Sugars (8)—Official First Action

(a) *Refined sugars.*—Polarizations of sugars testing ≥99, when made at temp. other than 20°, may be calcd to polarizations at 20° by following formula:

$$P_{20} = p_t [1 + 0.0003 (t - 20)],$$

where  $p_t$  = polarization at temp. read,  $t$ . (May be applied to beet sugar and raw cane sugars polarizing ≥96°S without appreciable error.)

(b) *Raw sugars.*—Polarization of raw cane sugars <96°S when made at temps other than 20°, may be calcd to polarizations at 20° by following formula:

$$P_{20} = p_t + 0.0015 (p_t - 80) (t - 20),$$

where  $p_t$  and  $t$  are same as in (a).

When % fructose in the sugar is known (in case of honeys and sugar cane products = ca ½ reducing sugars), use following formula:

$$P_{20} = p_t + 0.0003S (t - 20) - 0.00812F (t - 20),$$

where  $p_t$  and  $t$  are same as in (a);  $S$  = % sucrose; and  $F$  = % fructose.

These formulas give results agreeing closely with polarizations obtained at 20° if sugar is of av. normal composition.

### 31.023 Mutarotation—Procedure

Products, such as honey and com. glucose, that contain glucose or other reducing sugars in cryst. form or in soln at high density may show mutarotation under conditions prevailing during analysis. Only const rotation should be used in polarimetric methods. To obtain this, let soln prepd for polarization stand overnight before making reading. If it is desired to make reading immediately, heat neut. soln (pH ca 7.0) to bp or add few drops NH<sub>4</sub>OH, before dilg to vol.; or, if soln has been made to vol., add dry Na<sub>2</sub>CO<sub>3</sub> until just distinctly alk. to litmus paper. (Do not let slightly alk. solns stand at such high temps or for such lengths of time as to cause destruction of fructose.) Det. completion of mutarotation by making readings at 15–30 min intervals until const.

#### Sucrose in Absence of Raffinose

#### By Polarization Before and After Inversion with Invertase (9)—Official Final Action

### 31.024

#### ★ Reagent

*Invertase soln.*—Com. invertase prepnns are available (Invertase Scales (without melibiase), Wallerstein Co.). If it is desired to prep. soln in laboratory, method described in (1) may be

\* Designation D refers to Na light of 589.2 nm.

used. In either case, prepn may be further purified and concd by ultrafiltration method described in (3). Com. prepn may also be purified by dialysis and then reconcd by evapg *in vacuo* at temp.  $\leq 40^\circ$ .

(1) *Crude invertase soln.*—Mix yeast with  $H_2O$  in proportion of 10 lb compressed bakers yeast to 5 L  $H_2O$ . Add 2 L toluene and stir thoroly at frequent intervals during first 24 hr. Let stand 7 days with occasional stirring, and filter by gravity thru large fluted papers. Mix residue with 2 L  $H_2O$ , filter, and combine filtrates. Purify (J. Ind. Chem. **16**, 562(1924)) by adding 15 g neut.  $Pb(OAc)_2 \cdot 3H_2O$  to each L of ext and filtering on paper after all  $Pb(OAc)_2$  dissolves. Complete purification immediately by dialysis or by washing on ultrafilter as in (3).

(2) *Collodion ultrafilter (10).*—Dissolve 6 g sol. (in alcohol and ether mixt.) pyroxylin or nitrocellulose in mixt. of 50 mL absolute alcohol and 50 mL absolute ether by adding the alcohol to the cotton, letting mixt. stand in stoppered flask 10 min, adding the ether, and shaking. Let soln stand overnight. Pour ca 100 mL into 2 L graduate, and coat entire inside surface of graduate with the collodion. Drain, and dry 10 min. Fill graduate with  $H_2O$ , let stand 10–15 min, pour out  $H_2O$ , and remove collodion sack. Test for leaks by filling with  $H_2O$ . Slit open longitudinally and cut out circular piece 17–20 cm (7–8") diam. Cut bottom from 2 L bottle or erlenmeyer and grind edge smooth. Place it upon still moist collodion disk, fold edge of disk up around bottle, and cement it thereto with collodion that contains increased proportion of ether. Place 3 or 4 thicknesses of wet filter paper in 20 cm buchner. Place bottle with collodion membrane upon filter paper. Pour melted white petrolatum to depth of 2 cm between bottle and inside of funnel. Provide bottle with small mech. stirrer.

(3) *Washing and concentrating of invertase soln by ultrafiltration.*—Filter 4 L partially purified soln thru the ultrafilter, stirring continuously, until ca 1 L remains. Wash with distd  $H_2O$  added from const level device until filtrate is colorless (3 or 4 L of wash  $H_2O$  is required). Discard filtrate and transfer invertase soln to stoppered bottle. During entire process and in storage, preserve invertase soln with toluene.

(4) *Activity of invertase soln.*—Following test for activity of invertase soln is usually adequate: Dil. 1 mL invertase prepn to 200 mL. Transfer 10 g sucrose (granulated sugar) to sugar flask graduated at 100 and 110 mL, dissolve in ca 76 mL  $H_2O$ , add 2 drops HOAc, and dil. to 100 mL mark. To the 100 mL sugar soln add 10 mL dil. invertase soln and mix thoroly and rapidly, noting exact time at which solns are mixed. After exactly 60 min, make portions of soln just distinctly alk. to litmus paper with anhyd.  $Na_2CO_3$  and polarize in 200 mm tube at  $20^\circ$ . If invertase soln is sufficiently active, alk. soln will polarize ca  $31^\circ S$  without correcting for diln to 110 mL and optical activity of invertase soln.

If more exact information concerning activity of invertase prepn is desired, det. its velocity const as follows: Dil. 1 mL invertase soln to 200 mL at  $20^\circ$ ; place in const temp. bath at  $20^\circ$ ; and when soln reaches this temp., pipet 20 mL into flask contg 200 mL sucrose soln (10 g/100 mL concn) previously made distinctly acid to Me red (corresponding to pH ca 4.6) by addn of HOAc and also brought to temp. of  $20^\circ$  in same bath. Mix thoroly and promptly, and note time at which invertase soln was added. Keep sucrose-invertase mixt. in const temp. bath; remove portions after 15, 30, and 45 min; immediately after removing, make each portion just distinctly alk. to litmus paper with anhyd.  $Na_2CO_3$ , and polarize at  $20^\circ$ . Correct all polarizations for polarization of invertase soln. Calc. velocity const,  $k$ , for each of polarizations (at time  $t$ ) subsequent to initial polarization by following formula:

$$k = [\log_{10} 1.32 R_0 - \log_{10} (R_t + 0.32 R_0)]/t,$$

where  $k$  = unimolecular reaction velocity constant;  $t$  = number of min elapsing from time invertase and sucrose solns were mixed until inversion was stopped by addn of  $Na_2CO_3$ ;  $R_0$  = initial polarization (calcd by multiplying polarization of sucrose soln by 10/11 and correcting for polarization of invertase soln); and  $R_t$  = polarization at time  $t$ .

Invertase soln of sufficient activity (JAOAC **11**, 168 (1928); **16**, 79(1933); **17**, 74(1934)) should yield av. value for  $k$  (for various time periods) of  $\geq 0.1$ , after multiplying  $k$  value directly obtained by 200 in order to correct for initial diln of invertase soln. Diln of invertase soln mentioned above is made solely for purpose of detg its activity; original, undild invertase soln is used as inverting reagent in detn of sucrose, **31.025**, unless activity of original invertase soln greatly exceeds  $k$  value of 0.1, and it is desirable to conserve invertase. In this case, dil. to  $k$  value of 0.1, which is done in same manner as dilg other solns to std strength. Activity of invertase prepn required for rapid inversion, **31.025(c)**, is same as that needed for overnight inversion, **31.025(b)**, but proportion of invertase prepn used in former case is twice that used in latter.

### 31.025

#### Determination

(a) *Direct reading.*—Dissolve double normal wt of sample (52 g), or fraction thereof, in  $H_2O$  in 200 mL vol. flask; add necessary clarifying agent, **31.021(a)**, **(b)**, or **(d)**, avoiding excess; shake, dil. to vol. with  $H_2O$ , mix well, and filter, keeping funnel covered with watch glass. Reject first 25 mL filtrate.

If Pb clarifying agent was used, remove excess Pb from soln when enough filtrate collects by adding anhyd.  $Na_2CO_3$ , little at time, avoiding excess; mix well and refilter, rejecting first 25 mL filtrate. (Instead of weighing 52 g into 200 mL flask, two 26 g portions may be dild to 100 mL each, and treated exactly as described. Depending on color of product, multiples or fractions of normal wt may be used, and results calcd to basis of 26 g/100 mL.)

Pipet one 50 mL portion Pb-free filtrate into 100 mL vol. flask, dil. to vol. with  $H_2O$ , mix well, and polarize in 200 mm tube. Result, multiplied by 2, is direct reading ( $P$  of formula given below) or polarization before inversion. (If 400 mm tube is used, reading equals  $P$ .) If there is possibility of mutarotation, proceed as in **31.023**.

(b) *Invert reading.*—First det. vol. of HOAc necessary to make 50 mL of the Pb-free filtrate distinctly acid to Me red; then to another 50 mL Pb-free soln in 100 mL vol. flask add requisite vol. of acid and 5 mL invertase soln, fill flask with  $H_2O$  nearly to 100 mL, and let stand overnight (preferably at  $\geq 20^\circ$ ).

Cool, and dil. to 100 mL at  $20^\circ$ . Mix well and polarize at  $20^\circ$  in 200 mm tube. If in doubt as to completion of hydrolysis, let portion of soln remain several hr and again polarize. If there is no change from previous reading, inversion is complete. Carefully note reading and temp. of soln. If it is necessary to work at temp. other than  $20^\circ$ , which is permissible within narrow limits, complete vols and make both direct and invert readings at same temp. Correct polarization for optical activity of invertase soln and multiply by 2. Calc. % sucrose,  $S$ , by following formula:

$$S = \frac{100(P - I)}{132.1 - 0.0833(13 - m) - 0.53(t - 20)},$$

where  $P$  = direct reading, normal soln;  $I$  = invert reading, normal soln;  $t$  = temp. at which readings are made; and  $m$  = g total solids from original sample in 100 mL inverted soln. To obtain  $m$  for liqs, det. total solids in original sample as % by wt, as in **31.011**, and multiply this figure by wt original sample in 100 mL invert soln.

(c) *Rapid inversion at 55–60° (11).*—If more rapid inversion is desired, proceed as follows: Prep. sample as in (a) and to 50 mL Pb-free filtrate in 100 mL vol. flask add enough HOAc to render soln distinctly acid to Me red, 31.024(4). Det. vol. of HOAc required before pipetting 50 mL portion as in (b). Add 10 mL invertase soln, mix thoroly, place flask in H<sub>2</sub>O bath at 55–60°, and let stand at that temp. 15 min, shaking occasionally.

Cool, add Na<sub>2</sub>CO<sub>3</sub> until distinctly alk. to litmus paper, dil. to 100 mL at 20°, mix well, and det. polarization at 20° in 200 mm tube. Let soln remain in tube 10 min and again det. polarization. If there is no change from previous reading, mutarotation is complete. Carefully note reading and temp. of soln. Correct polarization for optical activity of invertase soln and multiply by 2. Calc. % sucrose by formula given in (b).

If soln has been made so alk. as to cause destruction of sugar, polarization, if neg., will in general decrease, since decomposition of fructose ordinarily is more rapid than that of other sugars present. If soln has not been made alk. enough to complete mutarotation quickly, polarization, if neg., will in general increase. As analyst gains experience he may omit polarization after 10 min if he has satisfied himself that he is adding enough Na<sub>2</sub>CO<sub>3</sub> to complete mutarotation at once without causing any destruction of sugar during period intervening before polarization.

### 31.026 *By Polarization Before and After Inversion with Hydrochloric Acid (12)—Official Final Action*

(a) *Direct reading.*—Prep soln as in 31.025(a). Pipet 50 mL Pb-free filtrate into 100 mL vol. flask; add 2.315 g NaCl and 25 mL H<sub>2</sub>O. Dil. to vol. with H<sub>2</sub>O at 20° and polarize in 200 mm tube at 20°. Multiply reading by 2 to obtain direct reading.

(b) *Invert reading.*—Pipet 50 mL portion Pb-free filtrate into 100 mL vol. flask and add 20 mL H<sub>2</sub>O. Add, little by little, while rotating flask, 10 mL HCl (sp gr 1.1029 at 20/4° or 24.85° Brix at 20°). Heat H<sub>2</sub>O bath and adjust heater to keep bath at 60°. Place flask in H<sub>2</sub>O bath, agitate continuously ca 3 min, and leave flask in bath exactly 7 min longer. Place flask at once in H<sub>2</sub>O at 20°.

When contents cool to ca 35°, dil. almost to mark. Leave flask in bath at 20° at least 30 min longer and finally dil. to mark. Mix well and polarize soln in 200 mm tube provided with lateral branch and H<sub>2</sub>O jacket, keeping temp. at 20°. This reading must be multiplied by 2 to obtain invert reading. If it is necessary to work at temp. other than 20°, which is permissible within narrow limits, vols must be completed and both direct and invert polarizations must be made at exactly same temp.

Calc. % sucrose, *S*, by following formula:

$$S = \frac{100(P - I)}{132.56 - 0.0794(13 - m) - 0.53(t - 20)},$$

where *P* = direct reading, normal soln; *I* = invert reading, normal soln; *t* = temp. at which readings are made; and *m* = g total solids from original sample in 100 mL inverted soln. To obtain *m* for liqs, det. total solids in original sample as % by wt as in 31.011, and multiply this figure by wt original sample in 100 mL invert soln.

(c) *Inversion at room temperature.*—Inversion may also be accomplished as follows: (1) Pipet 50 mL Pb-free filtrate into 100 mL vol. flask, add 20 mL H<sub>2</sub>O and 10 mL HCl (sp gr 1.1029 at 20/4° or 24.85° Brix at 20°), and set aside 24 hr at ≥22°; or (2) set aside 10 hr if >28°. Dil. to 100 mL at 20° and polarize as in (b). Under these conditions formula must be changed to following:

$$S = \frac{100(P - I)}{132.66 - 0.0794(13 - m) - 0.53(t - 20)},$$

## Sucrose and Raffinose (13)

### *By Polarization Before and After Treatment with Two Enzyme Preparations—Official Final Action*

#### 31.027

#### Reagents

(a) *Invertase soln (top yeast extract).*—See 31.024. This soln should be free from enzyme melibiase. Its invertase activity should be at least as great as that used for detn of sucrose in absence of raffinose, 31.024(4). Com. available.

(b) *Invertase-melibiase soln (bottom yeast extract).*—Prep. as in 31.024, using bottom fermenting brewers yeast instead of bakers yeast. Invertase activity should be at least as great as in (a). Obtainable only from brewers as a liq. Compress by filtering on buchner.

Test melibiase activity of soln as follows: Add 2 mL soln to be tested to 20 mL weakly acid melibiose soln polarizing +20.0°S and let stand 30 min at ca 20°. Add enough Na<sub>2</sub>CO<sub>3</sub> to make soln slightly alk. to litmus paper. Prepn suitable for overnight hydrolysis of solns contg ≤0.2 g raffinose in 100 mL should have hydrolyzed 35% of melibiose present under conditions mentioned; prepn suitable for overnight hydrolysis of solns contg ≤0.65 g raffinose in 100 mL should have produced 50% hydrolysis of melibiose; and prepn suitable for overnight hydrolysis of solns contg 0.65–1.3 g raffinose in 100 mL should have hydrolyzed at least 70% of melibiose present under above conditions. Preps of melibiose soln that polarize +20°S before hydrolysis will polarize +16.4°, +14.9°, and +12.9°S after 35, 50, and 70% hydrolysis, resp.

#### 31.028

#### Determination

With sugar beet products, weigh material specified in Table 31:01, transfer to 300 mL vol. flask, add vol. basic Pb(OAc)<sub>2</sub> soln, 31.021(a), indicated in table, and dil. to vol. at 20°. Mix thoroly and filter thru fluted paper in closely covered funnel, rejecting first 25 mL filtrate. When enough filtrate collects, remove Pb from soln by adding NH<sub>4</sub>H<sub>2</sub>PO<sub>4</sub> in as small excess as possible, Table 31:01. This condition is readily detd after little practice by appearance of Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> ppt, which usually flocculates and settles rapidly in presence of slight excess of the salt. Mix well and filter, again rejecting at least first 25 mL filtrate.

Make direct polarization in 200 mm tube at 20° unless soln contains appreciable amt of invert sugar, in which case pipet 50 mL portion Pb-free filtrate into 100 mL flask, dil. with H<sub>2</sub>O to vol., mix well, and polarize at 20°, preferably in 400 mm tube. This reading, calcd to normal wt of 26 g in 100 mL and 200 mm tube length, is direct reading (*P*) of formula given below for polarization before inversion.

Transfer two 50 mL portions of the Pb-free filtrate to 100 mL vol. flasks. To one add 5 mL invertase soln (top yeast ext) and to other 5 mL invertase-melibiase soln (bottom yeast ext); let stand overnight at room temp. (preferably ≥20°), dil. to vol., mix well, and polarize at 20°, preferably in 400 mm jacketed tube.

If rapid hydrolysis is desired, add 10 mL of each of the enzyme solns to 50 mL portions Pb-free filtrate in 100 mL vol. flasks and place in H<sub>2</sub>O bath 40 min at 50–55°. Then add Na<sub>2</sub>CO<sub>3</sub> until soln is slightly alk. to litmus paper, dil. to vol. at 20°, mix well, and polarize at 20°, preferably in 400 mm tube. Correct invert readings for optical activity of enzyme soln and calc. polarization to that of normal wt soln of 26 g/100 mL; also calc. reading to 200 mm tube length, if necessary.

Calc. % of anhyd. raffinose, *R*, and sucrose, *S*, from following formulas:

$$R = 1.354(X - Y);$$

$$S = \frac{(P - 2.202X + 1.202Y)100}{132.12 - 0.00718[132.12 - (P - 2.202X + 1.202Y)]}$$

where *P* = direct polarization, normal soln; *X* = corrected polarization after top yeast hydrolysis, normal soln; and *Y* = corrected polarization after bottom yeast hydrolysis, normal soln.

Quantities *X* and *Y* are treated algebraically.

### 31.029 By Polarization Before and After Inversion with Hydrochloric Acid—Official Final Action

(Of value chiefly in analysis of beet products)

If direct reading is  $>1^\circ$  higher than % sucrose as calcd by formula given in 31.026(b), raffinose is probably present. Calc. sucrose and raffinose by following formulas (J. Ind. Eng. Chem. 13, 793(1921)).

When polarizations are made at  $20^\circ$ :

$$S = (0.514P - I)/0.844, \text{ and } R = (0.33P + I)/1.563,$$

where *P* = direct reading, normal soln; *I* = invert reading, normal soln; *S* = % sucrose; and *R* = % anhyd. raffinose.

For all temps other than  $20^\circ$ :

$$S = \frac{P(0.478 + 0.0018t_2) - I(1.006 - 0.0003t_1)}{(0.908 - 0.0032t_2)(1.006 - 0.0003t_1)},$$

and

$$R = \frac{P(0.43 - 0.005t_2) + I(1.006 - 0.0003t_1)}{(1.681 - 0.0059t_2)(1.006 - 0.0003t_1)},$$

where  $t_1$  = temp. of direct polarization; and  $t_2$  = temp. of invert polarization.

### 31.030 Sucrose by Double Dilution Method (14) Official Final Action

(Applicable to substances in which vol. of combined insol. matter and ppt from clarifying agents is  $>1$  mL from 26 g)

Weigh 13 g sample and dil. to 100 mL, using appropriate clarifier (basic  $\text{Pb}(\text{OAc})_2$  for dark-colored confectionery or molasses, and alumina cream for light-colored confectionery). Also weigh 26 g sample and dil. this second soln with clarifier to 100

mL. Filter both solns, and obtain direct polariscopic readings. Invert each soln as in 31.025(b) or (c) or 31.026(b) or (c) and obtain resp. invert readings.

True direct polarization of sample = 4 times direct polarization of dild soln minus direct polarization of undild soln. True invert polarization = 4 times invert polarization of dild soln minus invert polarization of undild soln. Calc. sucrose from true polarizations thus obtained, using formula in 31.025(b) or 31.026(b) or (c) corresponding to method of inversion used.

### Sucrose—Chemical Methods

#### 31.031 From Reducing Sugars Before and After Inversion—Official Final Action

Det. reducing sugars as in 31.038 (clarification having been effected with neutral  $\text{Pb}(\text{OAc})_2$  as in 31.021(d)) and calc. to invert sugar from 52.019. Invert soln as in 31.025(b) or (c), or 31.026(b) or (c); exactly neutze acid; and again det. reducing sugars, but calc. them to invert sugar from table, 52.019, using invert sugar alone column. Deduct % invert sugar obtained before inversion from that obtained after inversion and multiply difference by 0.95 to obtain % sucrose. Dil. solns in both detns so that  $\leq 230$  mg invert sugar is present in amt taken for reduction. It is important that all Pb be removed from soln with anhyd. powd K oxalate before reduction.

### Commercial Glucose (Approximate) Polarimetric Methods—Procedure

#### 31.032 Substances Containing Little or No Invert Sugar

Com. glucose cannot be detd accurately, since amts of dextrin, maltose, and dextrose present vary. However, in sirups in which amt of invert sugar is too small to appreciably affect result, com. glucose may be estd approx. by following formula:

$$G = (a - S)100/211,$$

where *G* = % com. glucose solids; *a* = direct polarization, normal soln; and *S* = % cane sugar.

Express results in terms of com. glucose solids polarizing  $+211^\circ\text{S}$ . (Result may be recalcd in terms of com. glucose of any polarization desired.)

Table 31:01 Amounts of Sample and Reagents Required for Clarification and Deleading of Beet Sugar-House Products

Material	Amount per 100 mL	Basic Lead Acetate (55° Brix)	Ammonium Dihydrogen Phosphate
	gram	mL	gram
Cossettes <sup>a</sup>	13	3	0.2
Pulp	100 mL <sup>b</sup>	2–4	0.2
Lime cake or sewer <sup>c</sup>	26.5	1.5	.... <sup>d</sup>
Thin juice	52	2	0.2–0.3
Thick juice	26	4	0.3–0.4
White massecuite	13 or 26	3 or 6	0.3–0.7
High wash sirup	13 or 26	3 or 6	0.3–0.7
High green sirup	13 or 26	5 or 10	0.3–0.7
Raw or remelt massecuite	13	6	0.3–0.4
Raw or remelt sugar	26	3–4	0.3–0.4
Sugar melter	26	2–3	0.3–0.4
Low wash sirup	13	8–10	0.4–0.5
Low green sirup or molasses	13	10	0.4–0.5
Saccharate cakes and milk (carbonated)	26	4–6	0.3–0.4
Steffen waste and wash waters <sup>c</sup>	78 or 50 mL	2–3	0.2

<sup>a</sup> Usual method of extn, 26 g in 201.2 mL.

<sup>b</sup> Dil. to 110 mL.

<sup>c</sup> Neutze with  $\text{HAOC}$  before adding basic  $\text{Pb}(\text{OAc})_2$ .

<sup>d</sup> As Ca in soln will be partly pptd by the phosphate, it is necessary to add enough phosphate to complete pptn of both Pb and Ca salts, and no definite quantity can be specified.

**31.033 Substances Containing Invert Sugar**

Prep. inverted half-normal soln of substance as in **31.026(b)**, except cool soln after inversion, make neut. to phthln with NaOH soln, slightly acidify with HCl (1+5), and treat with 5–10 mL alumina cream, **31.021 (b)**, before dilg to vol. Filter, and polarize at 87° in 200 mm jacketed metal tube. Multiply reading by 200 and divide by factor 196 to obtain amt of com. glucose solids polarizing +211°S. (Result may be recalcd in terms of com. glucose of any polarization desired.)

**Invert Sugar—Chemical Methods****I. Lane-Eynon General Volumetric Method (15)  
Official Final Action****31.034****Reagents**

*Soxhlet modification of Fehling soln.*—Prep. by mixing equal vols of (a) and (b) immediately before use.

(a) *Copper sulfate soln.*—Dissolve 34.639 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , dil. to 500 mL, and filter thru glass wool or paper. Det. Cu content of soln (preferably by electrolysis, **31.044**) and so adjust that it contains 440.9 mg Cu/25 mL.

(b) *Alkaline tartrate soln.*—Dissolve 173 g KNa tartrate.  $4\text{H}_2\text{O}$  (Rochelle salt) and 50 g NaOH in  $\text{H}_2\text{O}$ , dil. to 500 mL, let stand 2 days, and filter thru prepd asbestos, **31.037**.

(c) *Invert sugar std soln.*—1%. To soln of 9.5 g pure sucrose, add 5 mL HCl and dil. with  $\text{H}_2\text{O}$  to ca 100 mL. Store several days at room temp. (ca 7 days at 12–15° or 3 days at 20–25°); then dil. to 1 L. (Acidified 1% invert sugar soln is stable for several months.) Neutze aliquot with ca 1 N NaOH and dil. to desired concn immediately before use.

**31.035****Standardization**

Accurately pipet 10 or 25 mL mixed Soxhlet reagent, or 5 or 12.5 mL each of Soxhlet solns **31.034(a)** and (b), into 300–400 mL erlenmeyer. (Amt of Cu taken differs slightly between 2 methods of pipetting, and method used must be consistent in stdzn and detn.) Prep. std soln of pure sugar of such concn that >15 mL and <50 mL is required to reduce all the Cu. Dispense from buret with offset tip to keep tube out of steam. To det. mg sugar required to completely reduce Cu at different concns, consult **52.017** and **52.018**. Add sugar soln within 0.5–1.0 mL of total required, heat cold mixt. to bp on wire gauze over burner, and maintain moderate boiling 2 min (coarse grains of C or other suitable inert material may be used to prevent bumping). Without removing flame add 1 mL 0.2% aq. methylene blue soln (or 3–4 drops 1% soln) and complete titrn within total boiling time of ca 3 min by small addns (2–3 drops) of sugar soln to decoloration of indicator. (Maintain continuous evolution of steam to prevent reoxidn of Cu or indicator.) After complete reduction of Cu, methylene blue is reduced to colorless compd and soln resumes orange  $\text{Cu}_2\text{O}$  color which it had before addn of indicator.

Multiply titer by mg/mL std soln to obtain total sugar required to reduce the Cu. Compare with tabulated value in **52.017** or **52.018** to det. correction, if any, to be applied to table. Small deviations from tabulated values may arise from variations in technic or composition of reagents. If only approx. results (within 1%) are required, stdzn may be omitted, provided specifications of analysis are rigidly observed.

**31.036****Determination**

(a) *Incremental method.*—If approx. concn of sugar in sample is unknown, proceed by incremental method of titrn. To 10 or 25 mL mixed Soxhlet soln, add 15 mL sugar soln and heat to bp

over wire gauze. Boil ca 15 sec and rapidly add further amts of sugar soln until only faintest perceptible blue remains. Then add 1 mL 0.2% aq. methylene blue soln (or 3–4 drops 1% soln) and complete titrn by adding sugar soln dropwise. (Error resulting from this titrn will generally be  $\leq 1\%$ .)

(b) *Standard method.*—For higher precision repeat titrn, adding almost entire sugar soln required to reduce all Cu and proceed as in **31.035**. From **52.017** or **52.018** find total reducing sugar corresponding to titer and apply correction previously detd. Calc. as follows: total reducing sugar required  $\times 100/\text{titer}$  = mg sugar in 100 mL.

**II. Munson-Walker General Method (16)  
Official Final Action****31.037****Reagents**

*Asbestos.*—Digest asbestos, amphibole variety (*Caution:* See **51.086**), with HCl (1+3) 2–3 days. Wash acid-free, digest similar period with 10% NaOH soln, and then treat few hr with hot alk. tartrate soln, **31.034(b)** (alk. tartrate solns that have stood for some time may be used for this purpose). Wash asbestos alkali-free; digest several hr with  $\text{HNO}_3$  (1+3); and after washing acid-free, shake with  $\text{H}_2\text{O}$  into fine pulp. In prepg gooch, make film of asbestos 6 mm thick and wash thoroly with  $\text{H}_2\text{O}$  to remove fine particles. If pptd  $\text{Cu}_2\text{O}$  is to be weighed as such, wash crucible with 10 mL alcohol and then with 10 mL ether; dry 30 min at 100°, cool in desiccator, and weigh.

Other reagents and solns used are described in **31.034**. Solns may be clarified by neut.  $\text{Pb}(\text{OAc})_2$  soln, **31.021(d)** (never basic  $\text{Pb}(\text{OAc})_2$ ). Remove excess Pb with dry Na oxalate.

**31.038****Precipitation of Cuprous Oxide**

Transfer 25 mL each of  $\text{CuSO}_4$  and alk. tartrate solns to 400 mL beaker of alkali-resistant glass and add 50 mL reducing sugar soln; or if smaller vol. of sugar soln is used, add  $\text{H}_2\text{O}$  to make final vol. 100 mL. Heat beaker on asbestos gauze over Bunsen burner, regulate flame so that boiling begins in 4 min, and continue boiling exactly 2 min. (It is important that these directions be strictly observed. To regulate burner for this purpose it is advisable to make preliminary tests, using 50 mL reagent and 50 mL  $\text{H}_2\text{O}$ , before proceeding with actual detn. Elec. heater may be used instead of burner.) Keep beaker covered with watch glass during heating.

Filter hot soln at once thru asbestos mat in porcelain gooch, using suction. Wash ppt of  $\text{Cu}_2\text{O}$  thoroly with  $\text{H}_2\text{O}$  at ca 60° and either weigh directly as  $\text{Cu}_2\text{O}$ , **31.039**, or det. amt of reduced Cu by one of methods described in **31.040–31.044**. Conduct blank detn, using 50 mL reagent and 50 mL  $\text{H}_2\text{O}$ , and if wt  $\text{Cu}_2\text{O}$  obtained is >0.5 mg, correct result of reducing sugar detn accordingly. Alk. tartrate soln deteriorates on standing, and wt  $\text{Cu}_2\text{O}$  obtained in blank increases.

**Determination of Reduced Copper****31.039 By Direct Weighing of Cuprous Oxide**

(Use only for detns in solns of reducing sugars of comparatively high purity. In products contg large amts of mineral or org. impurities, including sucrose, det. Cu in the  $\text{Cu}_2\text{O}$  by one of methods described in **31.040–31.044**, since the  $\text{Cu}_2\text{O}$  is likely to be contaminated with foreign matter.)

Prep. gooch as in **31.037**. Collect pptd  $\text{Cu}_2\text{O}$  on mat as in **31.038**; wash thoroly with hot  $\text{H}_2\text{O}$ , then with 10 mL alcohol, and finally with 10 mL ether. Dry ppt 30 min in oven at 100°, cool, and weigh. Obtain wt invert sugar equiv. to wt  $\text{Cu}_2\text{O}$  from **52.019**.

Number of mg  $\text{Cu}_2\text{O}$  reduced by given amt of reducing sugar varies, depending upon whether or not sucrose is present. In

table, absence of sucrose is assumed except in entries under invert sugar and lactose, where, in addn to columns for these alone, columns are given for their mixts with sucrose in specified ratios in the case of lactose and in specified amts of total sugar in 50 mL soln in the case of invert sugar.

(Later Hammond table has replaced original Munson-Walker table, where applicable.)

### By Titration with Sodium Thiosulfate (17)

#### 31.040

#### Reagent

**Thiosulfate std soln.**—Prep. soln contg 39 g  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ /L. Accurately weigh 0.2–0.4 g pure electrolytic Cu and transfer to 250 mL erlenmeyer roughly marked at 20 mL intervals. Dissolve Cu in 5 mL  $\text{HNO}_3$  (1+1), dil. to 20 or 30 mL, boil to expel red fumes, add slight excess satd  $\text{Br-H}_2\text{O}$ , and boil until Br is completely removed. Cool, and add 10 mL  $\text{NaOAc}$  soln (574 g trihydrate/L). Prep. 42 g/100 mL KI soln made very slightly alk. to avoid formation and oxidn of HI. Add 10 mL of the KI soln and titr. with  $\text{Na}_2\text{S}_2\text{O}_3$  soln to light yellow. Add enough starch indicator, **6.005(f)**, to produce marked blue. As end point nears, add 2 g KSCN and stir until completely dissolved. Continue titrn until ppt is perfectly white. 1 mL  $\text{Na}_2\text{S}_2\text{O}_3$  soln = ca 10 mg Cu.

It is essential for  $\text{Na}_2\text{S}_2\text{O}_3$  titrn that concn of KI in soln be carefully regulated. If soln contains <320 mg Cu, at completion of titrn 4.2–5 g KI should have been added for each 100 mL total soln. If greater amts of Cu are present, add KI soln slowly from buret with const agitation in amts proportionately greater.

#### 31.041

#### Determination

Wash pptd  $\text{Cu}_2\text{O}$ , cover gooch with watch glass, and dissolve the  $\text{Cu}_2\text{O}$  with 5 mL  $\text{HNO}_3$  (1+1) directed under watch glass with pipet. Collect filtrate in 250 mL erlenmeyer roughly marked at 20 mL intervals, and wash watch glass and gooch Cu-free. Proceed as in **31.040**, beginning, "... boil to expel red fumes, ..." Obtain wt reducing sugar equiv. to wt Cu from **52.019**.

### By Titration with Potassium Permanganate (18)

#### 31.042

#### Reagents

(a) **Potassium permanganate std soln.**—Approx. 0.1573*N*, and contg 4.98 g/L. Prep. and stdze as in **50.025–50.026**, using 0.35 g Na oxalate.

(b) **Ferric sulfate soln.**—Dissolve 135 g  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  or 55 g anhyd.  $\text{Fe}_2(\text{SO}_4)_3$  in  $\text{H}_2\text{O}$ , and dil. to 1 L. Det.  $\text{Fe}_2(\text{SO}_4)_3$  in stock supply by strong ignition to  $\text{Fe}_2\text{O}_3$ . Titr. 50 mL  $\text{Fe}_2(\text{SO}_4)_3$  soln, acidified with 20 mL 4*N*  $\text{H}_2\text{SO}_4$ , with  $\text{KMnO}_4$  soln, and use this titer as 0-point correction.

(c) **Ferrous phenanthroline indicator.**—Dissolve 0.7425 g *o*-phenanthroline. $\text{H}_2\text{O}$  in 25 mL 0.025*M*  $\text{FeSO}_4$  soln (6.95 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ /L).

#### 31.043

#### Determination

Filter the  $\text{Cu}_2\text{O}$  thru gooch, and wash beaker and ppt thoroly. Transfer asbestos pad to beaker with glass rod. Add 50 mL  $\text{Fe}_2(\text{SO}_4)_3$  soln and stir vigorously until  $\text{Cu}_2\text{O}$  is completely dissolved. Examine for complete soln, holding beaker above eye level.  $\text{Cu}_2\text{O}$  must be quant. transferred; if necessary, immerse crucible in soln and make sure adhering  $\text{Cu}_2\text{O}$  is dissolved. Remove crucible with glass rod and wash with  $\text{H}_2\text{O}$ . Add 20 mL 4*N*  $\text{H}_2\text{SO}_4$  and titr. with std  $\text{KMnO}_4$  soln. As end point approaches, add 1 drop ferrous phenanthroline indicator. At end point, brownish soln changes to green. Obtain wt reducing sugar equiv. to wt Cu from **52.019**.

### 31.044 By Electrolytic Deposition from Nitric Acid Solution (19)

Decant hot soln, **31.038**, thru asbestos mat in gooch, and wash beaker and ppt thoroly with hot  $\text{H}_2\text{O}$ . Transfer asbestos mat from crucible to beaker with glass rod and rinse crucible with 14 mL  $\text{HNO}_3$  (1+1), letting rinsings flow into beaker. After  $\text{Cu}_2\text{O}$  dissolves, dil. to 100 mL, heat to bp, and continue boiling ca 5 min to remove oxides of N. Cool, filter, transfer to 250 mL beaker, and dil. to 200 mL. Add 1 drop 0.1*N* HCl and mix thoroly.

For electrolysis use cylindrical electrodes of Pt gauze, ca 4 and 5 cm diam., resp., and ca 4.5 cm high, thoroly cleaned, ignited, cooled in desiccator, and weighed. Insert electrodes in Cu soln so that surface of cathode clears anode by  $\geq 5$  mm and both electrodes almost touch bottom of beaker. Cover with split watch glass to avoid loss by spattering. Electrolyze with current of 0.2–0.4 amp until deposition is complete, usually overnight. (Wash down sides of beaker and watch glass with  $\text{H}_2\text{O}$ , thus raising level of soln and exposing new surface of cathode; if new surface shows deposit of Cu, electrolysis is not complete.)

Without interrupting current, slowly lower beaker and at same time wash electrodes with stream of  $\text{H}_2\text{O}$ . Immediately immerse electrodes in another beaker of  $\text{H}_2\text{O}$  and break current. (Siphon can be used for washing, adding  $\text{H}_2\text{O}$  as soln is removed. Displacement of  $\text{HNO}_3$  soln is complete when current ceases to flow.) Rinse cathode with alcohol and dry few min in oven at 100°. Cool in desiccator and weigh.

Electrolyte may be stirred by rotating anode or mech. stirrer. In this case, current may be increased to 1–2 amp, thus shortening time required for complete deposition of Cu to ca 1 hr.

If extreme care is taken to avoid spattering,  $\text{Cu}_2\text{O}$  can be dissolved by letting  $\text{HNO}_3$  flow down walls of crucible. Keep crucible covered as much as possible with small watch glass. Collect filtrate in beaker, and wash watch glass and tip of pipet with jet of  $\text{H}_2\text{O}$ . Continue as above, beginning "... dil. to 100 mL, ..." Obtain wt reducing sugars equiv. to wt Cu from **52.019**.

### 31.045 ★ III. Ofner Volumetric Method (20) ★ Official Final Action

(For materials contg small amts of invert sugar in presence of sucrose)

See **29.046–29.047**, 10th ed.

### 31.046 ★ IV. Meissl-Hiller Gravimetric Method ★ Official Final Action

(For materials contg >1.5% invert sugar and <98.5% sucrose)

See **29.048**, 10th ed.

### 31.047 ★ V. Quisumbing-Thomas Method (21) ★ Official First Action

See **31.048–31.049**, 11th ed.

### VI. Berlin Institute Method (22)—Official First Action

(Applicable to dark-colored solns without defecation)

#### 31.048

#### Reagent

**Müller's soln.**—Dissolve 35 g  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  in 400 mL boiling  $\text{H}_2\text{O}$ . Sep. dissolve 173 g KNa tartrate. $4\text{H}_2\text{O}$  (Rochelle salt) and 68 g  $\text{Na}_2\text{CO}_3$  in 500 mL boiling  $\text{H}_2\text{O}$ . Cool, mix the 2 solns, and dil. to 1 L. Shake with small amt of C and filter. If ppt forms on storage, refilter.

★ Surplus method—see inside front cover.

**31.049****Determination**

Select amt of sample (10 g or less) contg  $\leq 30$  mg invert sugar. Pipet 10 mL Müller's soln and 100 mL sugar soln into 300 mL flask and cover. Mix thoroly and heat exactly 10 min in H<sub>2</sub>O bath boiling so vigorously that immersion of flask does not interrupt boiling. Place flask so that H<sub>2</sub>O level is  $\geq 2$  cm above surface of liq. in flask. After heating period, cool flask rapidly without agitation. Add 5 mL 5N HOAc to cooled soln, mix, and immediately add excess 0.0333N I soln (20–40 mL) from buret. After all Cu<sub>2</sub>O ppt dissolves, titr. excess I with 0.0333N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

Apply following corrections to mL I soln consumed: (1) mL I required in blank with H<sub>2</sub>O instead of sugar soln; (2) mL I required by sugar soln in detn conducted without heating; (3) 2.0 mL I for reducing action of 10 g sucrose or proportionate correction for smaller amt of sucrose. After these corrections 1 mL 0.0333N I = 1 mg invert sugar.

**Glucose—Chemical Methods****31.050 Lane-Eynon General Volumetric Method**  
**Official Final Action**

Proceed as in 31.036, referring titer to 52.017 or 52.018.

**31.051 Munson-Walker General Method**  
**Official Final Action**

Proceed as in 31.038 and obtain wt glucose from 52.019.

**Shaffer-Somogyi Micro Method—Official Final Action****31.052****Reagents**

(a) *Shaffer-Somogyi carbonate 50 reagent, 5 g KI.*—Dissolve 25 g each of anhyd. Na<sub>2</sub>CO<sub>3</sub> and KNa tartrate.4H<sub>2</sub>O (Rochelle salt) in ca 500 mL H<sub>2</sub>O in 2 L beaker. Add thru funnel with tip under surface, with stirring, 75 mL of soln of 100 g CuSO<sub>4</sub>.5H<sub>2</sub>O/L. Add 20 g NaHCO<sub>3</sub>, dissolve, and add 5 g KI. Transfer soln to 1 L vol. flask, add 250 mL 0.100N KIO<sub>3</sub> (3.567 g dissolved and dild to 1 L), dil. to vol., and filter thru fritted glass. Age overnight before use.

(b) *Iodide-oxalate soln.*—Dissolve 2.5 g KI and 2.5 g K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> in H<sub>2</sub>O and dil. to 100 mL. Prep. fresh weekly.

(c) *Thiosulfate std soln.*—0.005N. Prep. daily from stdzd stock 0.1N soln, 50.037–50.038.

(d) *Starch indicator.*—Rub 2.5 g sol. starch and ca 10 mg HgI<sub>2</sub> in little H<sub>2</sub>O. Dissolve in ca 500 mL boiling H<sub>2</sub>O.

**31.053****Determination**

Pipet 5 mL soln contg 0.5–2.5 mg glucose into 25 × 200 mm test tube. Add 5 mL reagent, (a), and mix well by swirling. Prep. blank, using 5 mL H<sub>2</sub>O and 5 mL reagent. Place tubes, capped with bulb or funnel, in boiling H<sub>2</sub>O bath 15 min. Carefully remove tubes without agitation to running H<sub>2</sub>O cooling bath 4 min. Remove caps and add down side of each tube 2 mL KI-K<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln and then 3 mL 2N H<sub>2</sub>SO<sub>4</sub> (56 mL/L). (Do not agitate solns while alk.) Mix thoroly to ensure that all Cu<sub>2</sub>O is dissolved, and let stand in cold H<sub>2</sub>O bath 5 min, mixing twice during that time. Titr. with 0.005N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, using starch indicator, (d). Subtract titrn of test soln from that of blank and det. amt glucose in 5 mL soln from Table 31.02.

Make control detns with known amts of glucose and apply corrections for any deviations from tabulated equivs.

**31.054 ★ Folin and Wu Micro Method (23) ★**  
**Official First Action**

J. Biol. Chem. 100, 695(1933); 160, 61(1945); JAOAC 42, 341(1959); 43, 645(1960).

**Jackson-Mathews Modification of Nyns  
Selective Method (24)**

**31.057****Reagent**

*Ost soln.*—Dissolve 250 g anhyd.  $K_2CO_3$  in ca 700 mL hot  $H_2O$ , add 100 g pulverized  $KHCO_3$ , and agitate mixt. until completely dissolved. Cool, and add, with very vigorous agitation, soln of 25.3 g  $CuSO_4 \cdot 5H_2O$  in 100–150 mL  $H_2O$ . Dil. to 1 L and filter.

**31.058****Determination**

Transfer 50 mL Ost soln to 125 mL erlenmeyer and pipet in vol. sample soln contg  $\leq 92$  mg fructose or its equiv. of fructose-glucose mixt. (glucose has ca  $1/12$  reducing power of fructose). Add  $H_2O$  to 70 mL. Immerse in  $H_2O$  bath regulated at  $55^\circ$ , preferably within  $0.1^\circ$ . Digest exactly 75 min, swirling at 10 or 15 min intervals.

Filter pptd  $Cu_2O$  on closely packed asbestos-mat gooch, and wash flask and ppt thoroly without attempting to transfer ppt quant. Det. Cu by one of methods described in **31.040–31.044**. As it is usually difficult to transfer Cu ppt quant. from erlenmeyer, select method of Cu analysis in which total Cu is dissolved in  $HNO_3$  and detd by electrolysis or  $Na_2S_2O_3$  titrn, or in  $Fe_2(SO_4)_3$  soln followed by  $KMnO_4$  titrn as in **31.043**.

See Table **31.03** for fructose equiv. If sample contained glucose in addn to fructose, anal. result is not true but "apparent" fructose, as glucose has appreciable reducing action under conditions of analysis. To det. correction for glucose, analyze sample also for total reducing sugars and compute true glucose and fructose by series of approximations. Calc. % reducing sugars in original sample and similarly % "apparent" fructose. Difference between these 2 percentages is "apparent" glucose. Divide apparent glucose by factor 12.4 and deduct result from apparent fructose to obtain new approximation to true fructose. Deduct new fructose % from total reducing sugar % to obtain more nearly correct value for true glucose and again divide by 12.4. Deduct quotient from original value of "apparent" fructose and continue approximation in same manner until % fructose remains essentially unaltered by 2 successive approximations.

If original sample contained sucrose, det. by means of Clerget method, **31.026**. Correct Cu for reducing action of sucrose before referring to Table **31.03**. 1, 2, 3, 4, and 5 g sucrose under conditions of analysis ppt 3.3, 5.7, 7.4, 8.5, and 9.0 mg Cu, resp.

**Table 31.03 Copper-Fructose Equivalents According to Jackson and Mathews Modification of Nyns Selective Method for Fructose; Values Expressed in mg**

(Linear interpolation yields accurate results)

Cu	Fructose	Cu	Fructose
5	2.5	130	39.3
10	4.5	140	42.0
15	6.2	150	44.7
20	7.9	160	47.4

**Maltose—Chemical Methods—Official Final Action**

**31.059 Lane-Eynon General Volumetric Method**

Proceed as in **31.036**, referring titer to **52.017** or **52.018**.

**31.060 Munson-Walker General Method**

Proceed as in **31.038** and **31.039**, and obtain wt maltose equiv. to wt  $Cu_2O$  from **52.019**.

**Lactose—Chemical Methods—Official Final Action**

**31.061 Lane-Eynon General Volumetric Method**

Proceed as in **31.036**, referring titer to **52.017** or **52.018**.

**31.062 Munson-Walker General Method**

Proceed as in **31.038** and **31.039**, and obtain wt lactose equiv. to wt of  $Cu_2O$  from **52.019**.

**31.063 Arabinose, Galactose, and Xylose and Other Sugars—Official First Action**

Proceed as in **31.053**, using appropriate heating time and equation for calcn from Table **31.04**. Make control detns with known amts of sugar and apply corrections for any deviations from equations.

**Table 31.04 Shaffer-Somogyi Sugar-Thiosulfate Equivalents**

$y$  = mg sugar in 5 mL;  $x$  = mL 0.005N  $Na_2S_2O_3$ .

Sugar	Heating Time, min	Equation
L-Arabinose	30	$y = 0.1234x + 0.060$
Fructose	15	$y = 0.1113x + 0.079$
D-Galactose	30	$y = 0.1332x + 0.033$
Glucose	15	$y = 0.1099x + 0.048$
Lactose	35	$y = 0.2031x + 0.030$
Maltose	30	$y = 0.2199x + 0.0725$
D-Mannose	35	$y = 0.1148x + 0.084$
D-Ribose	25	$y = 0.1381x + 0.098$
L-Sorbose	15	$y = 0.1244x + 0.116$
D-Xylose	30	$y = 0.1103x + 0.044$

**MOLASSES AND MOLASSES PRODUCTS (25)**

**31.064****Sampling—Procedure**

(a) *Liquid molasses.*—(1) *Molasses in barrels.*—Det. number of barrels to be sampled as follows: From lots of 1–10 barrels, sample all barrels; from lots of  $\geq 11$  barrels, sample 10 barrels. Take uniform amt from each barrel. Prep. composite from individual samples by mixing in container. Reduce composite to amt required and fill two  $\geq 500$  mL (1 pt) glass, stainless metal, or plastic jars. Close jars air-tight. Place one sample in cold storage (do not freeze) and put at disposal of second party as soon as possible. Send second sample to testing laboratory immediately after sampling.

(2) *Molasses in small retail containers.*—Content of intact and unopened container constitutes sample.

(3) *Molasses in tank cars, tank trucks, or storage tanks.*—(1) *Continuous drip sampling.*—Draw drip sample from pipeline as molasses is being pumped from vessel. From lot  $< 5000$  gal., collect  $\geq 1$  L (1 qt); from lot  $> 5000$  gal., draw 500 mL (1 pt) from each 5000 gal., but  $\geq 1$  L (1 qt).

(2) *Bacon bomb or thief sampling*.—Draw 2 similar complete samples of ca 1 L (1 qt) each consisting of continuous portion of core extending from top to bottom of tank. When for any reason such core cannot be obtained, draw three 1 L (1 qt) samples as follows: 1 portion from top just below surface of liq., 1 from center, and 1 from bottom of tank. Make composite for tank by combining samples from different levels as shown below.

Sample	Vessels of uniform cross section	Horizontal cylindrical tank (full)
Upper	1 part	1 part
Middle	3 parts	8 parts
Lower	1 part	1 part

Reduce composite to amt required and fill two  $\geq 500$  mL (1 pt) glass, stainless metal, or plastic jars. Close jars air-tight. Store and send for testing as in (a)(1).

(b) *Dried molasses*.—Proceed as in 7.001. Divide composite into 2 equal portions and place each portion into sep. air-tight jar. Store and send for testing as in (a).

### 31.065 *Transport of Samples*

Transport samples to laboratory as quickly as possible after sampling. Do not expose to direct sunlight or high temp. during transit.

### 31.066 *Preparation of Sample*

Let samples come to ca room temp. before opening containers.

(a) *Dried products*.—Do not grind. Pass samples contg lumps thru No. 8 sieve and crush retains on glass plate with glass or metal rolling pin, or in clean, dry mortar, using pestle. Mix entire sample thoroly and place in air-tight container.

(b) *Liquids*.—See 31.001(c).

### 31.067 *Moisture—Official Final Action*

(a) *Dried products*.—See 31.005.

(b) *Liquids*.—See 31.007 or 31.008.

### Moisture in Liquid Molasses (26)—Official Final Action

(Not applicable to molasses which fails to dissolve in MeOH within time specified for stability of end point of titrn assembly)

### 31.068 *Apparatus*

Buret with automatic zero; reservoir for reagent; mag. stirrer; titrn vessel (300 mL Berzelius beaker with stopcock attached to side at bottom for withdrawing excess soln is recommended), electrodes, and circuitry for deadstop end point detection. All openings must be tightly closed or protected with drying tubes to prevent contamination from atm. H<sub>2</sub>O. Various titrn assemblies may be obtained com. or one may be assembled.

Assemble titrn app. and follow manufacturer's instructions, setting for direct titrn. Set timer to give 30 sec end point. Add enough dry MeOH to cover electrodes on electrode probes and turn on stirrer. Adjust speed to obtain good stirring without splashing. Do not let stirrer bar contact electrodes. Titr. until satisfactory end point is reached. App. newly assembled or not recently used may require repetition of this step to dry out system. Test stability of end point obtained by continuing titrn beyond first 30 sec end point for same time required for titrn of

test sample. Generally end point should persist for 5 min to be assured of protection from atm. H<sub>2</sub>O contamination and instability of reagents.

### 31.069

### *Reagents*

(Caution: See 51.066, 51.072, and 51.081.)

(a) *Karl Fischer reagent*.—Available com. or prep. as follows: Dissolve 133 g I in 425 mL dry pyridine in dry g-s bottle. Add 425 mL dry MeOH or ethylene glycol monomethyl ether. (Less trouble with stopcock leakage is obtained with ethylene glycol monomethyl ether.) Cool to  $<4^{\circ}$  in ice bath and bubble in 102–105 g SO<sub>2</sub>. Mix well and let stand 12 hr. Reagent is reasonably stable, but restdze for each series of detns.

(b) *Anhydrous methanol*.—Reagent grade MeOH contg  $<0.1\%$  H<sub>2</sub>O. Prep. by distg over Mg.

### 31.070

### *Determination*

Add ca 120 mg H<sub>2</sub>O from weighing pipet or other suitable device and titr. with Karl Fischer reagent.

Calc.  $C = \text{mg H}_2\text{O/mL reagent}$ .

For titrn of molasses,  $C = \text{ca } 5 \text{ mg/mL}$ . Weigh molasses estd to give 20–40 mL titer into titrn app. and titr.

$\% \text{ H}_2\text{O} = (C \times \text{mL reagent})/(\text{g sample} \times 10)$ .

Drain excess liq. and repeat with succeeding samples. If time lapse occurs between titrn of samples, adjust liq. in titrn vessel to end point by titrn with reagent before adding next sample.

### 31.071 *Specific Gravity—Official Final Action*

See 31.010(b).

### 31.072 *Ash—Official Final Action*

See 31.012, 31.013, or 31.014.

### 31.073 *Soluble and Insoluble Ash—Official Final Action*

See 31.015.

### 31.074 *Mineral Adulterants in Ash—Official Final Action*

See 31.018.

### 31.075 *Nitrogen—Official Final Action*

See 31.019.

### 31.076 *Sucrose—Official Final Action*

Polarimetric methods (when required by law). See 31.020–31.030.

### Total Sugars Expressed as Invert Sugar Official Final Action

### *Lane-Eynon Constant Volume Volumetric Method*

### 31.077

### *Apparatus*

(a) *Electric heater*.—With white top and continuous temp. control over range 110–600°; attaining max. temp. within 5 min.

(b) *Buret*.—50 mL, graduated in 0.1 mL, with stopcock or pinchcock and offset delivery tube.

### 31.078

### *Reagents*

(a) *Soxhlet modification of Fehling soln*.—Prep. as in 31.034(a) and (b).

(b) *Invert sugar std solns*.—(1) *Stock soln*.—10 mg/mL. Prep. as in 31.034(c), using 5 mL HCl (sp gr 1.18 at 20/4°) and letting

stand 3 days at room temp. (20–25°). (2) *Working soln.*—5 mg/mL. Pipet 100 mL stock soln into 200 mL vol. flask, add few drops phthln, and neutze with 20% NaOH. Dil. to vol. and mix well. Prep. fresh daily.

**31.079****Preparation of Sample Solution**

(a) *Dried products containing not less than 30% total sugars.*—Weigh 8.00 g sample and transfer with 250 mL H<sub>2</sub>O, preheated to 60±5°, into 500 mL vol. flask. Mech. shake flask 30 min. Let stand addnl 30 min and cool to 20°. Dil. to vol. with H<sub>2</sub>O. Mix well and filter, using filter aid (Hyflo Super-Cel, or equiv.) and loose texture paper (Whatman No. 1, or equiv.). Discard first 25 mL filtrate. Cover funnel during filtration with watch glass to prevent evapn.

(b) *Liquids.*—Weigh 8.00 g sample and transfer with H<sub>2</sub>O to 500 mL vol. flask. Dissolve, and dil. to vol. with H<sub>2</sub>O. Proceed as in (a), beginning "Mix well . . ."

**31.080****Standardization of Soxhlet Reagent**

Fill 50 mL buret with working std soln contg 5 mg invert sugar/mL.

Accurately pipet 10 mL each Soxhlet soln, (a) and (b), into 300 mL erlenmeyer, mix, and add 30 mL H<sub>2</sub>O. Add from buret almost all std working soln (ca 19 mL) necessary to reduce the Cu. Add few boiling chips. Place cold mixt. on heater, regulate heat so that boiling will begin in ca 3 min, and maintain at moderate boil exactly 2 min, reducing heat, if necessary, to prevent bumping. Without removing flask from heater, add ca 4 drops 1% aq. *methylene blue soln* and complete titrn within total boiling time of ca 3 min by dropwise addn of working std soln at intervals of ca 10 sec until boiling mixt. resumes bright orange appearance which it had before indicator was added. Maintain continuous evolution of steam to prevent reoxidn by air. Repeat stdzn several times. Factor *F* is av. number mL std sugar soln required to completely reduce 20 mL Soxhlet soln. Use av. of ≥3 titrns.

**31.081****Inversion with Acid at Room Temperature**

Pipet 100 mL filtrate, **31.079**, into 200 mL vol. flask, and add 5 mL HCl (sp gr 1.18 at 20/4°). Let stand 24 hr at 20–25° or 10 hr at >25°. Add few drops phthln and neutze with 20% NaOH soln. Add few drops 0.5*N* HCl until red disappears. Dil. to vol. with H<sub>2</sub>O and mix well.

**31.082****Approximate Titration of Sample**

Det. approx. sugar content of sample as follows: Accurately pipet 10 mL each Soxhlet soln, (a) and (b), into 300 mL erlenmeyer, mix, and add 10 mL aliquot inverted sample soln. Add 40 mL H<sub>2</sub>O so that vol. H<sub>2</sub>O plus vol. sample soln is 50 mL, as in **31.080**. Mix without heating by swirling. Add few boiling chips. Place flask on heater, regulating heat so that boiling begins in ca 3 min. After liq. boils 10–15 sec, observe change in color of soln. If blue color persists, add working std sugar soln 0.5–1.0 mL at time, with few sec actual boiling after each addn until unsafe to add more without risk of passing end point. Add 3–4 drops methylene blue soln and continue adding sugar soln, ca 1 mL at time, at intervals of ca 10 sec, until indicator is completely decolorized. Calc. approx. % invert sugar in sample.

**31.083****Titration of Sample**

Pipet 10 mL each of Soxhlet soln, (a) and (b), into 300 mL erlenmeyer, mix, and add aliquot inverted sample soln as indicated in Table **31.05**. Add mL H<sub>2</sub>O specified in table so that vol. H<sub>2</sub>O plus vol. sample soln is 50 mL, as in **31.080**, and mix

without heating by swirling. Add few boiling chips. Place flask on heater, regulate heat so that boiling begins in ca 3 min, and during boiling, rapidly add working std invert sugar soln from buret, so that 0.5–1.0 mL is required to complete titrn. Continue as in **31.080**, beginning "Without removing flask . . ." Maintain moderate boiling.

$$\% \text{ Sugar as invert} = (F - M) \times I \times 100/W,$$

where *F* is Cu factor (mL std sugar soln required to reduce 20 mL mixed Soxhlet reagent); *M* is mL std sugar soln used in back-titrn of sample; *I* is g invert sugar in 1 mL working std sugar soln; and *W* is g sample in aliquot used. Report total sugars, expressed as invert.

**Table 31.05 Aliquots for Cane Sirups and Molasses**

mL H <sub>2</sub> O	mL Aliquot	g Sample in Aliquot	Total Sugar as Invert, %	
			Max.	Min.
40	10	0.08		73.00
35	15	0.12	82.00	58.00
30	20	0.16	61.00	41.00
25	25	0.20	49.00	35.00
20	30	0.24	41.00	29.00

**Invert Sugar—Official Final Action****31.084****Preparation of Sample Solution**

Proceed as in **31.079**. Then pipet 100 mL filtrate into 200 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix well.

**31.085****Titration of Sample**

Proceed as in **31.082–31.083**, except use aliquot of prepd sample soln without inversion as indicated in Table **31.06**.

**Table 31.06 Aliquots for Cane Sirups and Molasses (Without Inversion)**

mL H <sub>2</sub> O	mL Aliquot	g Sample in Aliquot	Total Sugar as Invert, %	
			Max.	Min.
40	10	0.16	61.00	40.00
35	15	0.24	40.00	30.00

10	40	0.64	15.00	12.00
—	50	0.80	12.00	8.00

**Unfermentable Reducing Substances (27)****Official Final Action**

(Applicable to molasses)

**31.086****Reagents**

(a) *Bakers yeast, free from starch.*—Fleischmann, sold in 1 lb units by Standard Brands, Inc., is suitable. May be stored for few days in refrigerator.

(b) *Neutral lead acetate soln.*—Dissolve 20 g Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.

(c) *Soxhlet soln.*—See **31.034(a)** and (b). Mix equal vols (a) and (b) immediately before use.

(d) *Potassium iodide soln.*—Dissolve 20 g KI in H<sub>2</sub>O and dil. to 100 mL.

(e) *Thiosulfate std soln.*—0.1*N*. See **50.037–50.038**.

**31.087****Fermentation**

Transfer 12 g blackstrap molasses (or 8 g high-test molasses) to 500 mL vol. flask, using 75 mL H<sub>2</sub>O. Add 25 g fresh yeast, coarsely chopped, and mix thoroly with molasses soln. Close flask with stopper provided with delivery tube, other end of which dips ca 1 cm below surface of H<sub>2</sub>O in beaker; or use any other type of fermentation trap. Place flask in H<sub>2</sub>O bath kept at 30° and let ferment ≥4 hr, shaking occasionally. (Incubator may be used and flask left overnight.)

When fermentation is complete, dil. mixt. with H<sub>2</sub>O, clarify with 15 mL neut. Pb(OAc)<sub>2</sub> soln, dil. to vol. at 20°, add teaspoonful of Filter-Cel, or equiv., shake well, and filter, discarding first few mL. Delead entire filtrate with ca 0.5 g anhyd. K oxalate and filter again with aid of Filter-Cel. Test filtrate for Pb. If necessary, add addnl K oxalate and refilter.

**31.088****Determination**

Transfer 25 mL final filtrate to 250 mL erlenmeyer, mix with 20 mL combined Soxhlet soln, and wash down wall of flask with 5 mL H<sub>2</sub>O, making 50 mL total. Add few pieces of ignited pumice stone and place flask on wire gauze covered with asbestos plate that has center hole slightly smaller than bottom of flask. Heat with Bunsen burner, or, preferably, elec. heater with temp. control. Heat to boiling in 3 min and boil gently exactly 2 min longer. Immediately close flask with stopper provided with Bunsen valve and cool quickly under H<sub>2</sub>O tap to prevent reoxidn. Add 15 mL KI soln and then 10 mL H<sub>2</sub>SO<sub>4</sub> (1+3). Titr. liberated I at once with 0.1N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, adding starch indicator toward end of titrn.

Det. blank with 75 mL H<sub>2</sub>O instead of molasses soln, adding yeast, etc., as above. Deduct titer of sample from titer of blank, and find mg invert sugar corresponding to difference from Table 31.07. Result, divided by 6 (in case of high-test molasses, by 4) gives directly % unfermentable reducing substances in the molasses, in terms of invert sugar.

**Table 31.07 Milligrams Invert Sugar Corresponding to 0.1N Thiosulfate**

0.1N Thiosulfate	Invert Sugar	0.1N Thiosulfate	Invert-Sugar
<i>mL</i>	<i>mg</i>	<i>mL</i>	<i>mg</i>

**CONFECTIONERY****31.089 Preparation of Sample—Official Final Action**

If composition of entire sample is desired, grind and mix thoroly. If sample is composed of layers or of distinctly different portions and it is desired to examine these individually, sep. with knife or other mech. means as completely as possible, and grind and mix each portion thoroly.

**31.090 Moisture—Official Final Action**

See 31.005, 31.006, 31.007, or 31.008.

**31.091 Ash—Official Final Action**

See 31.012 or 31.013.

**31.092 Soluble and Insoluble Ash—Official Final Action**

See 31.015.

**31.093 Alkalinity of Soluble Ash—Official Final Action**

See 31.016.

**31.094 Alkalinity of Insoluble Ash—Official Final Action**

See 31.017.

**31.095 Mineral Adulterants in Ash—Official First Action**

See 31.018.

**31.096 Nitrogen—Official Final Action**

Det. N in 2–5 g sample as in 2.057, using larger amt of H<sub>2</sub>SO<sub>4</sub> if necessary for complete digestion.

**Sucrose—Polarimetric Methods****31.097 In Absence of Raffinose—Official Final Action**

See 31.025, 31.026, or 31.030.

**Sucrose—Chemical Methods****31.098 By Reducing Sugars Before and After Inversion Official Final Action**

See 31.031.

**31.099 Commercial Glucose—Procedure**

See 31.032 or 31.033.

**Starch—Official First Action****31.100****Reagent**

**Malt extract.**—Use clean, new barley malt of known efficacy and grind only as needed. Grind well, but not so fine that filtration is greatly retarded. Prep. infusion of freshly ground malt just before use. For every 80 mL malt ext required, digest 5 g ground malt with 100 mL H<sub>2</sub>O at room temp. 2 hr, or 20 min if mixt. can be stirred by elec. mixer. Filter to obtain clear ext, refiltering first portions of filtrate if necessary. Mix infusion well.

**31.101****Determination**

Measure 25 mL of soln of uniform mixt. (representing 5 g sample) into 300 mL beaker, or add to beaker 5 g finely ground sample (previously extd with ether if sample contains much fat); add enough H<sub>2</sub>O to make 100 mL; heat to ca 60° (avoiding, if possible, gelatinizing starch); and let stand ca 1 hr, stirring frequently to secure complete soln of sugars. Transfer to wide-mouth bottle, rinse beaker with little warm H<sub>2</sub>O, and cool. Add equal vol. alcohol, mix, and let stand ≥1 hr.

Centrf. until ppt is closely packed on bottom of bottle and decant supernate thru hardened filter. Wash ppt with successive 50 mL portions of alcohol, 50% by vol., by centrfg and decanting thru filter until washings are sugar-free by following test: Add to test tube few drops of washings, 3 or 4 drops 20% a/c.  $\alpha$ -naphthol soln, and 2 mL H<sub>2</sub>O. Shake well, tip tube, let 2–5 mL H<sub>2</sub>SO<sub>4</sub> flow down side of tube, and then hold tube upright. If sugar is present, interface of 2 liqs is colored faint to deep violet; on shaking, whole soln becomes blue-violet. Transfer residue from bottle and hardened filter to beaker with 50 mL H<sub>2</sub>O.

Immerse beaker in boiling H<sub>2</sub>O, and stir constantly 15 min, or until all starch is gelatinized; cool to 55°, add 20 mL malt ext, and hold at this temp. 1 hr. Heat again to boiling few min, cool to 55°, add 20 mL malt ext, and hold at this temp. 1 hr, or until residue treated with I soln shows no blue tinge upon microscopic examination. Cool, dil. to 250 mL, and filter.

Place 200 mL filtrate in flask, add 20 mL HCl (sp gr 1.125), connect with reflux condenser, and heat in boiling H<sub>2</sub>O bath 2.5 hr. Cool, nearly neutze with 10% NaOH soln, finish neutzn with Na<sub>2</sub>CO<sub>3</sub> soln, and dil. to 500 mL. Mix soln thoroly, pour thru dry filter, and det. glucose in aliquot as in **31.038**. Conduct blank detn on same vol. of malt ext as used with sample and correct wt glucose accordingly. Wt glucose obtained  $\times 0.925$  = wt starch.

#### Ether Extract—Official First Action

(*Caution: See 51.011, 51.039, 51.054, 51.073, and 51.086.*)

#### 31.102 Continuous Extraction Method

Measure 25 mL 20% mixt. or soln into very thin, readily breakable glass evapg shell, or thin Pb or Sn foil contg 5–7 g freshly ignited asbestos fiber (*Caution: See 52.086*); or, if possible to obtain uniform sample, weigh 5 g mixed, finely divided sample into dish and wash with H<sub>2</sub>O onto asbestos in evapg shell, using small portion of asbestos fiber on stirring rod to transfer last traces of sample from dish to shell.

Dry to const wt at 100°, cool, wrap glass dish loosely in smooth paper, crush into rather small fragments between fingers, and carefully transfer crushed mass, including paper, to extn tube or fat extn cartridge. If metal dish is used, cut into small pieces and place in extn tube. Ext with anhyd. ether or pet ether (bp 45–60° and without weighable residue) in continuous extn app.  $\geq 25$  hr. In most cases it is advisable to remove substance from extractor after first 12 hr, grind with sand to fine powder, and re-ext remaining 13 hr. Transfer ext to weighed flask, evap. solv., and dry to const wt at 100°.

#### 31.103 Roese-Gottlieb Method

Introduce 4 g sample, or amt of uniform soln equiv. to this wt dry substance, into Mojonnier fat extn tube or similar app.; dil. to 10 mL with H<sub>2</sub>O, add 1.25 mL NH<sub>4</sub>OH, and mix thoroly. Add 10 mL alcohol and mix; then add 25 mL ether and shake vigorously ca 30 sec; and finally add 25 mL pet ether (bp <60°) and shake again ca 30 sec. Let stand 20 min or until sepn of liqs is complete.

Draw off as much as possible of ether-fat soln (usually 0.5–0.8 mL is left) into weighed flask thru small, rapid filter. (Weigh flask with similar one as counterpoise.) Again ext liq. remaining in tube, this time with 15 mL each of ether and pet ether; shake vigorously ca 30 sec with each solv. and let settle. Proceed as above, washing mouth of tube and filter with few mL of mixt. of equal parts of the 2 solvs (previously mixed and freed from deposited H<sub>2</sub>O).

For greater degree of accuracy, repeat extn. If previous solv.-fat solns have been drawn off closely, third extn usually yields  $\leq 1$  mg fat, or ca 0.02% with 4 g sample. Slowly evap. solv. on steam bath and then dry fat in 100° oven to const wt. Test purity of fat by dissolving in little pet ether. If residue remains, wash fat out completely with pet ether, dry residue, weigh, and deduct wt.

#### 31.104 Paraffin—Official First Action

To solv. ext in flask, **31.102** or **31.103**, add 10 mL alcohol and 2 mL NaOH soln (1+1); connect flask with reflux condenser; and heat 1 hr on H<sub>2</sub>O bath, or until saponification is complete.

Remove condenser and keep flask on bath until alcohol evaps and residue is dry. Dissolve residue as completely as possible in ca 40 mL H<sub>2</sub>O and heat on bath, shaking frequently. Wash into separator, cool, and ext with 4 successive portions of pet ether, collecting exts in weighed flask or capsule. Evap. pet ether and dry to const wt at 100°. Any phytosterol or cholesterol present in fat would be extd with the paraffin but amt is so insignificant that it may generally be disregarded.

#### 31.105 Shellac (28)—Official Final Action

(*Caution: See 51.011, 51.040, and 51.045.*)

Place 50 g sample in 400 mL beaker. Add 50 mL mixt. of benzene and absolute alcohol (1+1), and cover with watch glass. Heat to bp on steam bath, and simmer few min, stirring occasionally. Decant liq. into tared, round 100 mL glass dish with flat bottom ca 7 cm diam. Ext once more with benzene-alcohol mixt., and finally rinse with two 25 mL portions absolute alcohol, simmering and stirring each time. With moist sugar candy, avoid overheating to prevent pieces from sticking together.

Add each ext to glass dish previously placed on steam bath. Evap. until alcohol is just removed, rotating dish as it goes to dryness in order to spread ext uniformly over bottom surface. Avoid baking shellac on dish. If fat appears to be present, wash with three 15 mL portions pet ether, stirring and warming. Decant thru rapid filter.

Add mixt. of 25 mL *isoamyl alcohol* (bp 129–132°) and 25 mL benzene to filter, and filter back into dish. Heat on steam bath with stirring, cool somewhat, and transfer soln with suspended matter to 125 mL separator. Rinse dish with 25 mL hot (ca 60°) H<sub>2</sub>O, and add to separator; shake well and filter wash H<sub>2</sub>O if necessary. Repeat washing with H<sub>2</sub>O *twice* (or until washings are colorless), rinsing dish well around sides with first portions of liq. Finally, filter soln of shellac into tared dish, rinsing separator and filters with little absolute alcohol. Evap. to dryness on steam bath, rotating dish to give uniform film.

If much fat was extd in original benzene extn, wash final shellac residue with 25 mL pet ether, warming and stirring. Decant, dry on steam bath and in 100° oven, and weigh. After weighing, check for complete removal of sugars by thoroly rinsing dish and surface of shellac with hot H<sub>2</sub>O, warming on steam bath, decanting, rinsing down with alcohol, and evapg with care to give uniform film on dish. Dry and reweigh.

#### 31.106 Alcohol in Sirups Used in Confectionery ("Brandy Drops")—Official Final Action

Collect in beaker sirup from enough pieces of sample to yield 30–50 g, strain into weighed beaker, and weigh. Place sirup in 250–300 mL distg flask, dil. with half its vol. of H<sub>2</sub>O, attach flask to vertical condenser, and distil almost 50 mL, or as much of liq. as possible without causing charring. Foaming may be prevented by adding little *tannin*, or piece of *paraffin* ca size of pea. Cool distillate, dil. to vol. with H<sub>2</sub>O, and mix well. Det. sp gr as in **9.009–9.011**. Calc. % alcohol by wt or vol. in candy filling, using tables **52.003** and **52.005**.

### HONEY

#### 31.107 Preparation of Sample—Official Final Action

(a) *Liquid or strained honey.*—If sample is free from granulation, mix thoroly by stirring or shaking before weighing portions for detns; if granulated, place closed container in H<sub>2</sub>O bath without submerging, and heat 30 min at 60°; then, if necessary, heat at 65° until liquefied. Occasional shaking is

essential. Mix thoroly, cool rapidly as soon as sample liquefies, and weigh portions for detns. Do not heat honey intended for diastatic detn. If foreign matter, such as wax, sticks, bees, particles of comb, etc., is present, heat sample to 40° in H<sub>2</sub>O bath and strain thru cheesecloth in hot H<sub>2</sub>O funnel before weighing portions for analysis.

(b) *Comb honey*.—Cut across top of comb, if sealed, and sep. completely from comb by straining thru No. 40 sieve. When portions of comb or wax pass thru sieve, heat sample as in (a) and strain thru cheesecloth. If honey is granulated in comb, heat until wax is liquefied; stir, cool, and remove wax.

#### Color Classification (29)—Official First Action

##### 31.108

##### Apparatus

(a) *Containers*.—French sq bottles, screw finish, clear glass, 1.5 × 1.5", 2<sup>7</sup>/<sub>32</sub> oz. (Available from VirTis Co., Phoenix Precision Instrument Div., Rt 208, Gardiner, NY 12525.)

(b) *Comparator*.—All-metal boxes, ca 8 × 2 × 3" (20 × 5 × 7.5 cm), divided by thin partitions into 5 sq compartments, each of which has 2 windows, front and back, ca 1.2" (3 cm) sq. The 3 lighter glass stds (water white, extra white, and white) are mounted in 1 of comparator boxes on shelf against front windows in compartments 1, 3, and 5. The 3 darker stds (extra light amber, light amber, and amber) are mounted similarly in second comparator box. Place containers, (a), filled with H<sub>2</sub>O (blanks) behind glass stds. With turbid honeys, substitute containers filled with suspensions of diat. earth (Hyflo Super-Cel, or equiv.) designated as "Cloudy 1," "Cloudy 2," and "Cloudy 3," contg 100, 200, and 400 mg/L H<sub>2</sub>O, resp.

(c) *Glass stds*.—Use selected colored glasses tested and stdzd by USDA to correspond with color stds for honey.

Complete grading set is available from VirTis Co.

##### 31.109

##### Determination

Place clear blanks or cloudy suspensions in back of glass stds in compartments 1, 3, and 5 of 1 or both comparators. Pour sample (must be free from granulation) into clean, dry container, **31.108(a)**. Place sample container in compartment 2 or 4 of either comparator. Hold comparator at convenient distance from eye and view by diffused light (e.g., north or overcast sky, diffused light from W lamp, or white or daylight fluorescent lamp). Move sample from compartment to compartment, interchanging blanks with cloudy suspensions if necessary. Det. classification as follows: If sample is equal to water white std in hue, or not as red (i.e., yellower), classify as water white; if perceptibly redder than water white std in hue but not redder than extra white std, classify as extra white, etc. If redder in hue than amber std, classify as dark amber. Hue (amber quality or redness) is attribute of color in classification.

#### Moisture—Official Final Action

##### 31.110 Direct Drying

Proceed as in **31.007** or **31.008**, using weighed sample sufficient to yield ca 1 g solids. Add, if necessary, few mL H<sub>2</sub>O to incorporate sample thoroly with the sand. Dry at <70° (preferably 60°) under pressure ≤50 mm Hg (6.7 kPa).

##### 31.111 By Means of Refractometer (30)

Det. refractometer reading of honey at 20° and obtain corresponding % moisture from Table **31.08**. If detn is made at temp. other than 20°, correct reading to std temp. of 20° according to footnote.

##### 31.112 Ash (31)—Official Final Action

Weigh 5–10 g honey into ignited and weighed Pt dish. Place under 375 watt IR lamp with variable voltage input and slowly increase applied voltage until sample is black and dry and there is no danger of loss by foaming. Ash in furnace at 600° to const wt (overnight). Cool and weigh.

##### 31.113 Soluble Ash—Official Final Action

See **31.015**.

##### 31.114 Alkalinity of Soluble Ash—Official Final Action

See **31.016**.

##### 31.115 Nitrogen (31)—Official First Action

Det. N as in **47.021–47.023**, using 300 mg sample, 3.0 ± 0.1 mL H<sub>2</sub>SO<sub>4</sub>, and 1 hr digestion after acid comes to true boil. Titr. with 0.01N HCl and calc. % N.

#### Proline (32)—Official First Action

##### 31.116

##### Principle

Proline, predominant free amino acid of honey, reacts with acid ninhydrin soln to form colored compd. Interference from other amino acids is negligible, ≤5%.

##### 31.117

##### Reagents and Apparatus

(a) *Ninhydrin soln*.—3%. Dissolve 3.0 g ninhydrin in 100 mL peroxide-free ethylene glycol monomethyl ether. Store solv., not reagent, over Zn metal in amber bottle.

(b) *L-(−)-Proline*.—Eastman No. 2488; dry in vac. oven and store in desiccator. Prep std solns as follows: (1) *Stock soln*.—0.5 mg/mL H<sub>2</sub>O. Dil. 25 mg proline to 50 mL with H<sub>2</sub>O. Refrigerate. (2) *Working soln*.—50 μg/mL. Dil. 10 mL stock soln to 100 mL with H<sub>2</sub>O. Prep. fresh daily.

(c) *Reaction tubes*.—18 × 130 mm borosilicate screw-cap tubes with Teflon liners.

##### 31.118

##### Determination

Weigh 2.500 g honey, transfer to 50 mL vol. flask, and dil. to vol. with H<sub>2</sub>O. Pipet 0.5 mL into each of 3 reaction tubes, add 0.25 mL HCOOH and 1.00 mL ninhydrin soln. Cap tightly, shake well, and place in boiling H<sub>2</sub>O bath 15 min. Cool 5 min in 22° H<sub>2</sub>O bath, remove cap, and pipet 5 mL aq. isopropanol (1+1) into each. Mix well and det. *A* at 520 nm against blank of H<sub>2</sub>O carried thru method. Read all tubes within 35 min of cooling.

Correct for color of honey by detg *A* of soln contg 0.5 mL prep'd honey soln, 1.25 mL H<sub>2</sub>O, and 5.00 mL isopropanol (1+1). Subtract value from that of reacted sample before calcg.

Prep. calibration curve as in detn, using proline std soln instead of honey. *A* of 0.5 mL of soln of 50 μg proline/mL is ca 0.35 in 10 mm cell.

Calc. mg proline/100 g honey.

##### 31.119 Direct Polarization—Official First Action

(a) *Immediate direct polarization*.—Transfer 26 g honey to 100 mL vol. flask with H<sub>2</sub>O, add 5 mL alumina cream, **31.021(b)**, dil. to vol. with H<sub>2</sub>O at 20°, filter, and polarize immediately in 200 mm tube.

(b) *Constant direct polarization*.—Complete mutarotation as in **31.023**. If necessary to conserve sample, soln from tube used in immediate direct polarization, (a), may be returned to flask. Make final reading at 20° in 200 mm tube.

(c) *Mutarotation*.—Difference between (a) and (b) is measure of mutarotation.

**Table 31:08 Relationship Between Refractive Index and Water Contents of Honey<sup>a</sup>**

Water Content, %	Refractive Index			Water Content, %	Refractive Index		
	20°C <sup>b</sup>	60°F <sup>c</sup>	40°C		20°C <sup>b</sup>	60°F <sup>c</sup>	40°C

18.8	1.4895	1.4905	1.4850	24.8	1.4745		
				25.0	1.4740		

<sup>a</sup> Values for 20°C and 60°F are Wedmore's calculations (Bee World **36**, 197(1955)); 40°C values are calcd from Auerbach and Borries equation (Z. Nahr. Genusssm. **22**, 353–358(1924)). Values >22.0% were extended by FAO/WHO Codex Committee on Methods of Analysis and Sampling (1968).

<sup>b</sup> If refractive index is measured at temp. above (below) 20°C, add (subtract) 0.00023/°C above (below) 20°C before using table.

<sup>c</sup> If refractive index is measured at temp. above (below) 60°F, add (subtract) 0.00013/°F above (below) 60°F before using table.

(d) *Direct polarization at 87°*.—Polarize soln obtained in (b) at 87° in jacketed 200 mm metal tube.

### 31.120 Reducing Sugars—Official Final Action

(a) *Munson-Walker method*.—Dil. 10 mL soln, **31.119(a)**, to 250 mL and det. reducing sugars in 25 mL of this soln by **31.038**. Calc. result to % invert sugar.

(b) *Lane-Eynon method*.—Dil. 10 mL soln, **31.119(a)**, to 500 mL and det. reducing sugars by const vol. method:

Stdze Fehling solns, **31.034**, so that 5.00 mL soln (a) and 5 mL soln (b) will react completely with 50 mg invert sugar std soln, **31.034(c)**, added as 25 mL of diln to 2 g/L.

Pipet 5 mL of each Fehling soln into 250 mL erlenmeyer. Add 7 mL H<sub>2</sub>O, few boiling chips, and 15 mL dild honey soln from buret with offset tip. Heat to bp over wire gauze, and maintain moderate boil 2 min. Add 1 mL 0.2% methylene blue soln, or 3–4 drops 1% soln, while still boiling and complete titrn within total boiling time of 3 min by repeated small addns of dild honey soln until indicator is decolorized. (Observe color of supernate.) Note vol. honey soln used (x mL).

Repeat titrn, using 5 mL of each Fehling soln, (25 – x) mL H<sub>2</sub>O, and all but 1.5 mL dild honey soln (from buret) detd in preliminary titrn. Add honey soln to end point within 3 min and note vol. dild honey soln used (y mL). Duplicate titrns should agree within 0.1 mL.

% Invert sugar = 2000/(g honey sample × y).

### 31.121 Sucrose—Official Final Action

Proceed as in **31.031**. To det. reducing sugars after inversion,

invert 50 mL soln, **31.119(a)**, as in **31.025(b)** or (c) or **31.026(b)** or (c), dil. 10 mL this soln with small amt of H<sub>2</sub>O, neutze with Na<sub>2</sub>CO<sub>3</sub>, and dil. to 250 mL with H<sub>2</sub>O. Use 50 mL of this soln, making detn as in **31.120(a)**.

### 31.122 Dextrin (Approximate)—Procedure

Using ≤4 mL H<sub>2</sub>O, transfer 8 g sample (4 g for dark-colored honeydew honey) to 100 mL vol. flask by letting sample drain from weighing dish into flask and then dissolving residue in 2 mL H<sub>2</sub>O. Add this soln to flask, and rinse weighing dish with two 1 mL portions H<sub>2</sub>O, adding few mL absolute alcohol each time before decanting. Fill flask to vol. with absolute alcohol, shaking constantly. Set flask aside until dextrin collects on sides and bottom and liq. is clear.

Decant clear liq. thru filter paper and wash residue in flask with 10 mL alcohol, pouring washings thru same filter. Dissolve dextrin in flask with boiling H<sub>2</sub>O and filter thru paper already used, receiving filtrate in weighed dish prepd as in **31.008**. Rinse flask and wash filter number of times with small portions of hot H<sub>2</sub>O, evap. on H<sub>2</sub>O bath, and dry to const wt at 70° under pressure ≤50 mm Hg (6.7 kPa).

Dissolve weighed alcohol ppt in H<sub>2</sub>O and dil. to definite vol., using 50 mL H<sub>2</sub>O for each 0.5 g ppt or part thereof.

Det. reducing sugars in soln both before and after inversion as in **31.031**, expressing results as invert sugar. Calc. sucrose from results thus obtained and subtract sum of reducing sugars before inversion and sucrose from wt total alcohol ppt to obtain wt dextrin.

**Chromatographic Separation of Sugars**  
**Method I (33)—Official Final Action**

31.123

**Principle**

By adsorption of honey sample on charcoal column, followed by elution into monosaccharide, disaccharide, and higher sugar fractions, interference of disaccharides in glucose and fructose detns is eliminated. Elution is by progressively higher alcohol concns, followed by detn of individual monosaccharides, sucrose, and reducing disaccharides collectively as maltose, and trisaccharides and higher sugars collectively after hydrolysis.

31.124

**Preparation and Standardization  
of Absorption Column**

Column is 22 mm od  $\times$  370 mm long, with 1 L spherical section and  $\frac{3}{8}$  35/20 spherical joint at top. Adsorbent is 1 + 1 mixt. of Darco G-60 charcoal and rapid filter-aid (Celite 545 or Dicalite 4200). Insert glass wool plug, wet from below, and add enough dry adsorbent to dry tube (23–26 cm) to compress to 17 cm when vac. is applied with *gentle* tapping of column. Remove excess charcoal from walls of tube, and add filter-aid layer at top with *gentle* packing (1–1.5 cm). Wash column with 500 mL H<sub>2</sub>O and 250 mL 50% alcohol, and let stand overnight with 50% alcohol on it. Flow rate should be 5.5–8.0 mL/min with H<sub>2</sub>O at 9 lb/sq in. (62 kPa) pressure. Slower flow rates delay analyses excessively.

Alcohol content of eluting solns must be adjusted to retentive power of charcoal used. Wash column alcohol-free with 250 mL H<sub>2</sub>O, quant. add 10 mL soln of 1.000 g anhyd. glucose to top, and draw it into column with suction (do not let dry). Add 300 mL H<sub>2</sub>O to top, break suction, apply pressure ( $\leq 10$  lb/sq in.; 69 kPa), and collect eluate in five 50 mL portions in tared beakers. Include 10 mL from sample introduction in first 50 mL fraction. Evap. fractions on steam bath, dry in vac. oven at 80–100°, and weigh.

Decant remaining H<sub>2</sub>O from top of column, pass 50 mL 50% alcohol and then 250 mL H<sub>2</sub>O thru column, and repeat chromatgy, using 1.000 g anhyd. glucose in 10 mL 1% alcohol, washing with 250 mL 1% alcohol as above. Select as *sol/v. 1* that which removes glucose in 150 mL. Repeat chromatgy with 2% alcohol, if necessary.

Wash column with 250 mL H<sub>2</sub>O and then 20 mL 5% alcohol. To top, add 10 mL 5% alcohol soln contg 100 mg maltose and 100 mg sucrose. Elute as above with 250 mL 5% alcohol, weighing evapd 50 mL portions of filtrate. Repeat, if necessary, with 7, 8, and 9% alcohol to find *sol/v. 2* that will elute  $\geq 98\%$  disaccharides in 200 mL. *Sol/v. 1* previously selected must not elute disaccharides. Combinations found satisfactory with various charcoals are 1%, 7%; 2%, 8%; 2%, 9%. At conclusion, pass 100 mL 50% alcohol thru column, and store under layer of this solv.

31.125

**Preparation of Fractions**

Wash column with 250 mL H<sub>2</sub>O and decant any supernate. Pass 20 mL *sol/v. 1* thru column, and discard. Dissolve 1 g sample in 10 mL *sol/v. 1* in 50 mL beaker. Transfer sample (using long-stem funnel) onto column, and force into column. Use 15 mL *sol/v. 1* to rinse beaker and funnel, and add to column. Collect all eluate, beginning with sample introduction, in 250 mL vol. flask. Add 250 mL *sol/v. 1*, and collect exactly 250 mL total (fraction 1, monosaccharides). Decant excess solv. from top, add 265–270 mL *sol/v. 2*, and collect 250 mL in vol. flask (fraction 2, disaccharides). Decant excess, add 110 mL 50% alcohol (*sol/v. 3*), and collect 100 mL in vol. flask (fraction 3, higher sugars). Mix each fraction thoroly. Column may be stored

indefinitely, outlet closed, under 50% alcohol. Discard after 8 uses.

**Fructose**

31.126

**Reagents**

Use reagents in 31.052 and following:

(a) *Iodine soln.*—0.05*N*. Dissolve 13.5 g pure I in soln of 24 g KI in 200 mL H<sub>2</sub>O, and dil. to 2 L. Do not stdze.

(b) *Sodium sulfite soln.*—1%. Dissolve 1 g Na<sub>2</sub>SO<sub>3</sub> in 100 mL H<sub>2</sub>O. Make fresh daily.

(c) *Bromocresol green soln.*—Dissolve 150 mg bromocresol green in 100 mL H<sub>2</sub>O.

31.127

**Determination**

Pipet 20 mL fraction 1 into 200 mL vol. flask. Add 40 mL 0.05*N* I soln by pipet; then with vigorous mixing, add 25 mL 0.1*N* NaOH over 30 sec period, and immediately place flask in 18 $\pm$ 0.1° H<sub>2</sub>O bath. Exactly 10 min after alkali addn, add 5 mL 1*N* H<sub>2</sub>SO<sub>4</sub> and remove from bath. Exactly neutze I with Na<sub>2</sub>SO<sub>3</sub> soln, using 2 drops starch soln, 31.052(d), near end point. Back-titr. with dil. I if necessary. Add 5 drops bromocresol green and exactly neutze soln with 1*N* NaOH; then make just acid to indicator. Dil. to vol. and det. reducing value of 5 mL aliquots by Shaffer-Somogyi method, 31.053.

Make duplicate blanks and detns. Deduct titrn from that of blank and calc. fructose:

% Fructose =  $500[(\text{titer} \times 0.1150) + 0.0915] \times 100/\text{mg sample}$

Fructose correction for glucose detn = f.c. =  $[(\text{titer} \times 0.1150) + 0.0915] \times 40$ . Bracketed quantity is mg fructose in 5 mL aliquot, valid between 0.5 and 1.75 mg fructose.

**Glucose**

31.128

**Reagents**

*Sodium thiosulfate soln.*—0.05*N*. Prep. from stdzd stock 0.1000*N* soln, 50.037–50.038.

31.129

**Determination**

Pipet 20 mL fraction 1 into duplicate 250 mL erlenmeyers. Evap. to dryness on steam bath in air current. Add 20 mL H<sub>2</sub>O, pipet in 20 mL 0.05*N* I, and slowly add 25 mL 0.1*N* NaOH, as in fructose detn. Immediately place in 18 $\pm$ 0.1° H<sub>2</sub>O bath. Exactly 10 min after alkali addn, add 5 mL 2*N* H<sub>2</sub>SO<sub>4</sub>, remove from bath, and titr. with 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, using starch soln, 31.052(d).

Make duplicate blanks, using H<sub>2</sub>O, subtract titrn value from that of blank, and calc. glucose:

% Glucose =  $56.275[\text{titer} - (0.01215 \times \text{f.c.})] \times 100/\text{mg sample}$ ,

where f.c. = fructose correction from fructose detn. Equation is valid over range 10–15 mg glucose in 20 mL. In presence of glucose, 1 mg fructose requires 0.01215 mL 0.05*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, in range 15–60 mg fructose.

**Reducing Disaccharides as Maltose**

31.130

**Determination**

Pipet 5 mL aliquots of fraction 2 into 25  $\times$  200 mm test tubes, and det. reducing value as in 31.053, except boil tubes 30 min. Value for 15 min H<sub>2</sub>O blank may be used here. Calc. % reducing disaccharides as maltose:

% "Maltose" =  $50[(\text{titer} \times 0.2264) + 0.075] \times 100/\text{mg sample}$ .

Maltose correction for sucrose detn = m.c. = maltose titer  $\times$  0.92. Bracketed quantity is mg maltose in 5 mL aliquot, valid between 0.15 and 3.80 mg maltose. Reducing value of maltose at 15 min is 92% of final value.

**Sucrose****31.131****Determination**

Pipet 25 mL fraction 2 into 50 mL vol. flask. Add 5 mL 6*N* HCl and 5 mL H<sub>2</sub>O. Mix, let stand 17 min in 60° H<sub>2</sub>O bath, cool, and neutze to bromocresol green with 5*N* NaOH (103 g/500 mL). (Polyethylene squeeze bottle is excellent for holding and delivering alkali.) Adjust to acid color of indicator, using 2*N* H<sub>2</sub>SO<sub>4</sub> to correct over-run. Dil. to vol. and det. reducing value of 5 mL aliquots by Shaffer-Somogyi detn, **31.053**. Subtract titrn from blank, and calc. sucrose by ref. to curve constructed from following table:

Sucrose in 5 mL Aliquot Oxidized, mg	0.005 <i>N</i> Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> Required, mL
0.255	1.75
0.502	3.95
1.004	8.72
1.260	11.28

From curve obtain  $S_1$  = sucrose equiv. to maltose correction, **31.130**, and  $S_2$  = sucrose equiv. of sucrose titer.

$$\% \text{ Sucrose} = 50(2S_2 - S_1) \times 100/\text{mg sample.}$$

**Higher Sugars or "Dextrin"****31.132****Determination**

Pipet 25 mL aliquots of fraction 3 into 50 mL vol. flasks. Add 5 mL 6*N* HCl and 5 mL H<sub>2</sub>O, and heat 45 min in boiling H<sub>2</sub>O bath. Cool, neutze as for sucrose, dil. to vol., and det. reducing value by Shaffer-Somogyi detn, **31.053**. Subtract titrn value from blank and obtain glucose equiv. from curve constructed from following table:

Glucose, mg	Titer, mL
0.05	0.20
0.10	0.60
0.25	1.85
0.50	4.00
1.00	8.50
2.00	17.60

$$\% \text{ Higher sugars} = 40(\text{glucose equiv.}) \times 100/\text{mg sample.}$$

**Notes:** For most accurate work, Shaffer-Somogyi values must check within 0.04 mL. Calibration of all operations, including column, using known synthetic mixts of glucose, fructose, sucrose, maltose, and raffinose (corrected for moisture) is recommended for critical work. Sugar:mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> relations [(titer  $\times$  0.1150) + 0.0915] in equation for % fructose, and [(titer  $\times$  0.2264) + 0.075] in equation for % maltose, are obtained by analyzing known mixts of glucose and fructose for fructose, and known amts of maltose, resp., by method.

Efficiency of column sepn may be checked by paper chromatgy of fractions 1, 2, and 3 as in **31.145**.

**Alternative Method II (34)—Official First Action****31.133****Principle**

For use when sucrose is sugar of primary interest. Sugars are sepd by charcoal column, **31.124–31.125**. Glucose is detd in disaccharide fraction 2 by glucose oxidase before and after invertase hydrolysis and calcd to sucrose. Other sugars are detd by weighing residues of sepd fractions.

**31.134****Reagents**

(a) **Column.**—Prep. as in **31.124**. Alternatively, use slurry prepn: Place glass wool plug at bottom of column and add ca 1 cm dry filter aid (Dicalite 4200, or equiv.). Wet filter aid layer from below. With outlet open, add slurry of 20 g adsorbent mixt. in 200 mL H<sub>2</sub>O from top. Let drain 5 min and apply 27.6 kPa (4 psi) pressure until surface is stabilized. Then apply 69 kPa (10

psi) pressure, release, and remove excess adsorbent beyond 17 cm depth by suction from above. Add ca 1 cm filter aid. Wash column as in **31.124**.

(b) **Acetate buffer soln.**—0.1*M*, pH 4.5. Add 5.72 mL HOAc to 500 mL H<sub>2</sub>O, adjust to pH 4.5 with 1*M* NaOH, and dil. to 1 L.

(c) **Tris buffer soln.**—pH 7.6. To 48.44 g tris(hydroxymethyl)aminomethane (available as Trizma base, No. T 1503, Sigma Chemical Co.) in 500 mL H<sub>2</sub>O, add 384 mL 0.8*M* HCl, adjust to pH 7.6 if necessary, and dil. to 1 L.

(d) **Glucose oxidase-peroxidase reagent (GOP).**—Dissolve 120 mg glucose oxidase (Type II: purified, 15,000–20,000 units/g; Sigma Chemical Co. G 6125, or equiv.) and 32 mg peroxidase (Type I: from horseradish, salt-free powder; Sigma Chemical Co. P 8125, or equiv.) in 400 mL tris buffer, (c). Add soln of 270 mg *o*-tolidine.2HCl (available from Fisher Scientific Co. as Fisher certified T-320) in 520 mL H<sub>2</sub>O. Refrigerate in brown bottle. Filter before use, if necessary. Stable  $\geq 6$  weeks.

(e) **Invertase reagent.**—Dissolve 12.5 mg invertase (Grade VI, from baker's yeast, essentially melibiase-free, activity ca 200 units/mg; Sigma Chemical Co. I 5875, or equiv.) in 50 mL pH 4.5 acetate buffer soln, (b).

(f) **Glucose std soln.**—0.1 mg/mL. Dissolve 25.0 mg glucose (SRM 41, NBS) in 25 mL H<sub>2</sub>O in 250 mL vol. flask. Boil 2 min and dil. to vol. or dil. to vol. and hold final soln 2 hr before use.

**31.135****Preparation of Fractions**

Proceed as in **31.125**.

**31.136****Determination of Sugars**

(a) **Glucose.**—Dil. 5.00 mL fraction 1 to 100 mL and pipet 2 mL portions into each of two 18  $\times$  150 mm test tubes. Place tube with 2 mL H<sub>2</sub>O in rack, follow with 1 tube contg 2 mL std glucose soln (100  $\mu$ g/mL), the 2 sample tubes, then 1 std. Repeat sequence if addnl detns are to be made. At intervals appropriate to measuring technic to be used (i.e., 30 or 60 sec with flow-thru cells; longer as needed for manual cells), add 5.00 mL glucose oxidase reagent at room temp. to each tube, beginning with H<sub>2</sub>O tube, which will be reagent blank. After 60 min from addn of reagent, add 0.15 mL 4*N* HCl to first tube and mix thoroly with vortex mixer.

Continue same timing with other solns. Zero instrument with blank tube and det. *A* at 530 nm of each successive tube 1 min after addn of acid. Average *A* for each pair of sample tubes and calc. glucose concn, using av. *A'* of stds before and after corresponding sample tubes.

$$\mu\text{g Glucose in tube} = (A/A') \times \mu\text{g glucose in std tube}$$

% Glucose in honey =  $\mu\text{g glucose in tube} \times 2.5/\text{mg sample}$ , where factor 2.5 = 20 (diln factor)  $\times$  250 (vol. fraction)/(1000  $\mu\text{g/mg} \times 2$  (vol. in tube)).

(b) **Sucrose.**—Pipet 2 mL fraction 2 into each of four 18  $\times$  150 mm test tubes. Prep. 2 series, one control, other inverted. For each series, arrange in rack tube with 2 mL H<sub>2</sub>O, 2 sample tubes, tube with 2 mL glucose std, 2 sample tubes, etc., finishing with 2 mL glucose std. To all tubes in control series add 0.50 mL H<sub>2</sub>O; to all tubes in inverted series add 0.50 mL invertase reagent (or 0.50 mL pH 4.5 acetate buffer may be added to std tubes). Hold all tubes 30 min at room temp. Continue as in (a), beginning "At intervals appropriate . . .", beginning with inverted series followed by control series.

$$\mu\text{g Glucose} = (\mu\text{g glucose in std tube}) \times (A/A'),$$

$$\% \text{ Sucrose in honey} = 0.02375 (\mu\text{g glucose in inverted tube} - \mu\text{g glucose in control tube})/\text{g sample,}$$

where 0.02375 =  $\mu\text{g glucose} \times 1.9 \times 10^{-6} \times (1/2) \times 250 \times 100$ ;  $\mu\text{g glucose} \times 1.9 = \mu\text{g sucrose}$ ;  $10^{-6} = \mu\text{g/g}$ ;  $1/2 = 2$  mL analyzed; 250 = mL diln of sample; 100 = to convert to %.

## 31.137

**Distribution of Sugars**

Filter fractions if filter aid is visible. Evap. to dryness, on steam bath with current of air or N, 50.0 mL fraction 1, 100 mL fraction 2, and entire fraction 3, finally transferring each fraction to sep. weighed 50 mL beakers. Dry to const wt in vac. oven at  $\leq 95^\circ$ .

- % Monosaccharides = g fraction 1  $\times$  500/g sample,  
 % Disaccharides = g fraction 2  $\times$  250/g sample,  
 % Higher sugars = g fraction 3  $\times$  100/g sample.

**High Pressure Liquid Chromatographic Method (35)**  
**Official First Action**

## 31.138

**Apparatus**

(a) *Chromatograph*.—Waters Associates Model ALC/GPC, or equiv., with Model 6000A solv. delivery system and model U6K injector.

(b) *Detector*.—Waters Associates R-401 refractive index detector, or equiv.

(c) *Recorder*.—Varian Aerograph Model A-25 dual pen recorder, or equiv.

(d) *Column*.—300  $\times$  4 (id) mm  $\mu$ -Bondapak/Carbohydrate (Waters Associates, No. 84038).

(e) *Sample clarification kit*.—Available in kit form from Waters Associates (No. 26865), or equiv.; 0.45  $\mu$ m filters stable in org. solvs are suitable.

(f) *Syringes*.—10  $\mu$ L No. 701-N point style No. 1, 2  $\times$  0.020" od, 25 gage needle (Hamilton Co.).

## 31.139

**Reagents**

(a) *Mobile phase*.—Nonspectro acetonitrile (Burdick & Jackson Laboratories, Inc.) dild with H<sub>2</sub>O (83+17). Degas mobile phase daily by mag. stirring 15 min under vac.

(b) *Sugar std soln*.—Place 3.804 g fructose (Mallinckrodt Chemical Works), 3.010 g glucose (Mallinckrodt Chemical Works), and 0.602 g sucrose into 100 mL vol. flask, dissolve in 50 mL H<sub>2</sub>O, and add CH<sub>3</sub>CN to vol. Composition of std approximates 5 g honey dissolved in 50 mL aq. CH<sub>3</sub>CN (1+1).

## 31.140

**Operating Conditions**

Fructose, glucose, and sucrose are baseline sepd and quantitated in 20 min under following conditions: flow rate, 1.0 mL/min (ca 500 psig; 3.45 MPa); temp., ambient (ca 23°); detector (R-401), 8 $\times$  (fructose and glucose) and 2 $\times$  (sucrose); attenuation, 10 mv on recorder, detector set so that 380  $\mu$ g fructose gives full-scale deflection of pen; and chart speed, 0.1"/min. Mono-, di-, and trisaccharides are eluted from column in order of MW.

## 31.141

**Preparation of Sample**

Weigh 5.000 g sample in small beaker and transfer to 50 mL vol. flask with 25 mL H<sub>2</sub>O. Immediately dil. to vol. with CH<sub>3</sub>CN and filter thru 0.45  $\mu$ m filter, using sample clarification kit.

## 31.142

**Chromatography**

Inject 10  $\mu$ L std soln into chromatograph. Establish retention times, measure peak hts, and check reproducibility. Repeat for sample soln. Calc. glucose, fructose, and sucrose from integrator values or from peak hts as follows:

$$\text{Wt \% sugar} = 100 \times (PH/PH') \times (V/V') \times (W'/W)$$

where PH and PH' = peak hts (or integrator values) of sample and std, resp.; V and V' = mL sample and std (50 and 100) solns, resp.; and W and W' = g sample (5.000) and std, resp.

**Commercial Glucose****Qualitative Test (36)—Official Final Action**

## 31.143

**Reagent**

*Aniline-diphenylamine chromogenic reagent*.—Dissolve 500 mg diphenylamine.HCl and 0.55 mL redistd aniline in 50 mL acetone. Add 5 mL 85% H<sub>3</sub>PO<sub>4</sub>. Prep. fresh daily.

## 31.144

**Preparation of Sample**

Dil. sample with equal vol. H<sub>2</sub>O. To 0.5 mL in small centr. tube (11  $\times$  100 mm test tube) add 4 mL absolute alcohol, shake, and centr. Decant clear or slightly cloudy supernate, dissolve ppt in 0.5 mL H<sub>2</sub>O, reppt with 4 mL absolute alcohol, and centr. Decant, and dissolve ppt in 0.1 mL H<sub>2</sub>O. Apply 2  $\mu$ L to origin of chromatogram, as well as control spots of authentic honey and/or honeydew and corn sirup treated as above.

TLC method, 31.149(b), or paper chromatgc method, 31.145, may be used.

## 31.145

**Chromatography**

For details of performing paper chromatgy see 29.028 and JAOAC 40, 999(1957).

Ascending or descending is satisfactory. Suitable solv. for latter is *n*-PrOH-EtOAc-H<sub>2</sub>O (7+1+2). Equilibrate 45 min and irrigate  $\geq 40$  hr, letting solv. drip from serrated lower edge of paper. For shorter ascending use (ca 6 hr), roll paper into cylinder, staple edges, and set in cylindrical jar, using *isoamyl alcohol-pyridine-H<sub>2</sub>O* (7+7+6). To obtain increased resolution, dry paper and repeat irrigation  $\geq 1$  time.

Irrigate with suitable solv., remove, and dry paper chromatogram. Dip in chromogenic reagent, let acetone evap., and heat ca 5–8 min at 85–95° until control spots of corn sirup treated as above become blue. Honey or honeydew sample contg 5% of com. glucose shows series of blue maltodextrin spots of low *R<sub>F</sub>*, converging to origin. Honey and honeydew dextrin spots are distinctly brown or gray, not blue. If paper is heated excessively, both honey dextrin spots and maltodextrin spots will approach same shade of gray.

**Commercial Invert Sugar (37)****Resorcinol Test (38)—Procedure**

## 31.146

**Reagent**

*Resorcinol soln*.—Dissolve 1 g resublimed resorcinol in 100 mL HCl (sp gr 1.18–1.19).

## 31.147

**Test**

Dissolve 2 g honey in 10 mL H<sub>2</sub>O and ext rapidly with washed ether 30 min in continuous extractor, Fig. 12:01B. Conc. ether to ca 5 mL and transfer to test tube. Add 2 mL freshly prepd resorcinol soln, shake, and note color. Cherry red color appearing within 1 min indicates presence of com. invert sugar. Yellow to salmon shades have no significance.

*Note*: Resorcinol test, when neg., may not be regarded as conclusive evidence of absence of com. invert sugar sirup in honey.

**High Fructose Corn Sirup**

**Thin Layer Chromatographic Method (39)**  
**Official First Action**

## 31.148

**Apparatus and Reagents**

(a) *Charcoal column*.—Use column and adsorbent as in 31.124. Pack plug of fine glass wool in base of column; close

outlet tube and partly fill column with H<sub>2</sub>O. Open outlet and let H<sub>2</sub>O flow thru column to remove any air bubbles. Close outlet when H<sub>2</sub>O is ca 10 mL above glass wool; then add slurry of filter aid sufficient for ca 1 cm depth and let settle by gravity. Pour in slurry of 12 g adsorbent mixt. in 150 mL H<sub>2</sub>O. Drain 5 min, apply 4 psi (27.6 kPa) pressure until surface stabilizes and then 10 psi (69 kPa). Clean excess adsorbent from surfaces by vac. Add slurry of filter aid sufficient for 1–2 cm depth, and wash column with 500 mL H<sub>2</sub>O and 200 mL 50% alcohol, under which it may be stored. Before use, wash column with 250 mL H<sub>2</sub>O. (Vac. operation may be used, but pressure is preferred.) Flow rate of 8.5 mL/min at 10 psi is commonly achieved.

(b) *Plates*.—Coated with 250  $\mu$  thickness of silica gel G. Store in desiccator.

(c) *Solvent*.—*n*-Butanol-HOAc-H<sub>2</sub>O (2+1+1).

(d) *Color reagent*.—Dissolve 1 mL redistd aniline and 1 g diphenylamine.HCl in 50 mL acetone and add 5 mL H<sub>3</sub>PO<sub>4</sub>. As alternative to redistd aniline, proceed as follows: Dissolve 1 g aniline in 50 mL acetone and decolorize with decolorizing carbon (not Darco G-60). Filter, dil. to 50 mL and add diphenylamine and H<sub>3</sub>PO<sub>4</sub>. Make fresh daily or store at 0°

### 31.149

#### Detection

(a) *Preparation of sample*.—Weigh to nearest mg 1 g sample in 30 or 50 mL beaker. Add 10 mL H<sub>2</sub>O to dissolve and place on top of column. Force into column with suction but do not let run dry. Rinse beaker with two 5 mL portions H<sub>2</sub>O and force into column. Wash with 300 mL 7% alcohol, which is discarded, and then with 100 mL 50% alcohol. Evap. eluate in tared 50 mL beaker on steam bath in current of air or N, dry in vac. oven 0.5 hr at 65°, and weigh residue.

Transfer residue to 13 × 100 mm test tube with total of 1 mL H<sub>2</sub>O. Evap. to dryness in bath at ca 60° in current of air or N. Dissolve residue in 0.1 mL H<sub>2</sub>O for each 10 mg material.

(b) *Chromatography*.—Place solv. in tank 15 min before inserting plate. Apply 2 and 6 (2 × 3 or 3 × 2)  $\mu$ L of test soln to plate. Apply control spots of pure and adulterated honey, prep'd as above. Control solns may be preserved by freezing or drying. Place spotted plate in developing tank until solv. front approaches top of plate. Remove plate, dry, and spray thoroly with color reagent. (*Caution*: Avoid contact with spray.) Let acetone evap., and place in oven at 90–95° until spots are well developed (ca 7–10 min).

(c) *Interpretation*.—Pure honey will show 1 or 2 large blue-gray or blue-brown spots at *R<sub>f</sub>* ca >0.35. When wt of isolated carbohydrate fraction is  $\leq$ 15 mg (1.5%), any blue streaks or series of spots extending from origin provide conclusive evidence of presence of corn sirup, high fructose corn sirup (HFCS), including high fructose sirup derived from plant source other than corn. If wt is >15 mg, addnl test must be conducted to confirm adulteration. Repeat charcoal column pretreatment as follows: Prep. sample as in (a), except wash column with 100 mL 25% alcohol, discard this fraction, and wash with the 50% alcohol. Any blue streaks or series of spots extending from origin on TLC plate following this treatment provide conclusive evidence of adulteration.

#### Corn Sirup Products

##### Carbon Ratio Mass Spectrometric Method (40) Official Final Action

### 31.150

#### Principle

Sample is burned completely to CO<sub>2</sub> and H<sub>2</sub>O; CO<sub>2</sub> is purified, and <sup>13</sup>C to <sup>12</sup>C ratio is measured in isotope ratio mass spectrometer. Difference in <sup>13</sup>C/<sup>12</sup>C values for honey (av.  $\delta^{13}\text{C} = -25.4\text{‰}$ )

(parts per thousand)) and corn sirup (av.  $\delta^{13}\text{C} = -9.7\text{‰}$ ) provides measure of corn sirup (including high fructose corn sirup (HFCS)) in honey.

### 31.151

#### Apparatus

(a) *Combustion system*.—Vac.-tight glass manifold including quartz combustion tube  $\frac{1}{2}$  filled with CuO in tubular furnace, liq. N trap, automatic Toepler pump, and high-vac. source.

(b) *Purification system*.—Glass manifold interconnected with combustion system including trap, sample collection tube, and manometer (see Fig. 31:02 and *Geochimica et Cosmochimica Acta* 3, 54–55(1953)).

(c) *Mass spectrometer*.—Micromass 602 (new model 602D) (Kearns Group, 58 Buckingham Dr, Stamford, CT 06902), Nuclide 6-60-RMS (Nuclide, 642 E College Ave, State College, PA 16801), Varian MAT G D150 (superceded by MAT 250) (Varian MAT Mass Spectrometry, 25 Hanover Rd., Florham Park, NJ 07932), or equiv. instrument designed or modified for isotope ratio measurement and capable of accuracy of 0.01% of abundance at mass 45.

### 31.152

#### Preparation of Sample

Place 300–400 mg sample, weighed to nearest 0.1 mg, in ceramic boat, position boat in tube, and evacuate system. Admit to 600 mm Hg, tank O purified over CuO at 700°, followed by liq. N trap. Heat sample to  $\geq 850^\circ$  in manifold in tubular furnace, condensing CO<sub>2</sub> in liq. N trap. Recirculate gases over CuO 10–30 min at 850°. Isolate collection trap and purification system from combustion system and Toepler pump by valves, and pump off O. Cool purification trap with solid CO<sub>2</sub>-acetone; cool sample tube with liq. N. Let collection trap warm, condensing impurities in solid CO<sub>2</sub> trap and CO<sub>2</sub> in sample tube.

### 31.153

#### Determination

Operate mass spectrometer according to manufacturer's instructions. Calibrate with  $\geq 2$  stds such as NBS SRM 20 Solenhofen limestone ( $\delta^{13}\text{C} = -1.06\text{‰}$  against Pee Dee belemnite (PDB)), NBS SRM 21 graphite ( $\delta^{13}\text{C} = -27.8\text{‰}$ ), or NBS SRM 22 crude oil ( $\delta^{13}\text{C} = -29.5\text{‰}$ ). Correct values obtained for zero enrichment in inlet system, mixing between sampling and std valves, tailing of major onto minor peak signal, and contribution of <sup>17</sup>O to mass 45 signal. Calc.:

$$\delta^{13}\text{C}(\text{‰}) = \left[ \frac{{}^{13}\text{C}/{}^{12}\text{C sample}}{{}^{13}\text{C}/{}^{12}\text{C std}} - 1 \right] \times 1000.$$

Convert laboratory analyses, relative to whatever std was used, to PDB base by following relationship:

$$\delta_{(X - \text{PDB})} = \delta_{(X - B)} + \delta_{(B - \text{PDB})} + 10^{-3} \delta_{(X - B)} \delta_{(B - \text{PDB})},$$

where (X – B) and (X – PDB) refer to analyses of sample (X) relative to std (B) and relative to PDB, and (B – PDB) is analysis of std (B) relative to PDB, all  $\delta$ 's in parts per thousand.

Sample with  $\delta^{13}\text{C}$  value less negative than  $-21.5\text{‰}$  relative to PDB is considered adulterated.

#### Diastatic Activity of Honey (41)—Official Final Action

(Do not heat sample for this detn.)

### 31.154

#### Principle

Buffered sol. starch-honey soln is incubated and time required to reach specified end point is detd photometrically. Results are expressed as mL 1% starch hydrolyzed by enzyme in 1 g honey in 1 hr.

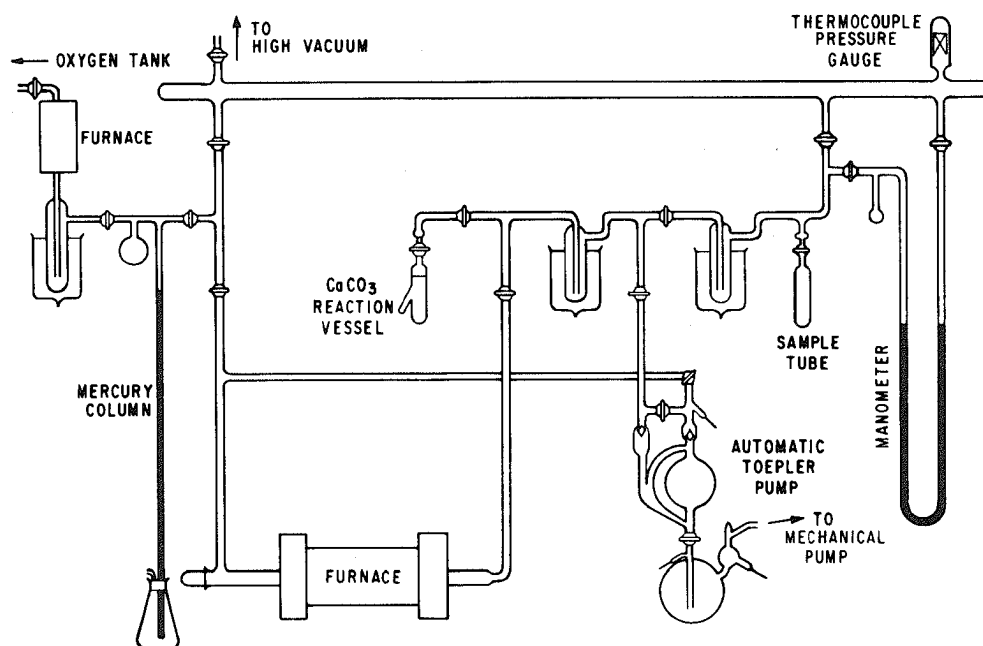

FIG. 31:02—Carbon combustion and purification system

Reprinted with permission from *Geochimica et Cosmochimica Acta*, 3, 54 (1953).

**31.155****Apparatus**

(a) *Reaction vessel*.—Attach sealed side arm, 18 × 60 mm, to 18 × 175 mm test tube. Lower side of side arm is attached 100 mm from bottom of tube, making 45° angle with lower portion of tube.

(b) *Photoelectric photometer*.—With 660 nm red filter or 600 nm interference filter and 1 cm cells.

**31.156****Reagents**

(a) *Iodine stock soln*.—Dissolve 8.80 g resublimed I in 30–40 mL H<sub>2</sub>O contg 22.0 g KI, and dil. to 1 L with H<sub>2</sub>O.

(b) *Iodine soln*.—0.0007*N*. Dissolve 20 g KI and 5.00 mL I soln, (a), in H<sub>2</sub>O and dil. to 500 mL. Prep. fresh every second day.

(c) *Acetate buffer soln*.—pH 5.3 (1.59*M*). Dissolve 87 g NaOAc·3H<sub>2</sub>O in 400 mL H<sub>2</sub>O, add ca 10.5 mL HOAc in H<sub>2</sub>O, and dil. to 500 mL. Adjust pH to 5.30 with NaOAc or HOAc, if necessary.

(d) *Sodium chloride soln*.—0.5*M*. Dissolve 14.5 g NaCl in H<sub>2</sub>O and dil. to 500 mL.

(e) *Starch soln*.—Weigh 2.000 g sol. starch (special for diastatic power detn, available from ASBC) and mix with 90 mL H<sub>2</sub>O in 250 mL erlenmeyer. Rapidly bring to bp, swirling soln as much as possible. Reduce heat and boil gently 3 min, cover, and let cool to room temp. Transfer to 100 mL vol. flask and dil. to vol. Observe details closely to limit variation in *A* values of starch-I blank.

**31.157****Standardization**

Pipet 5 mL starch soln into 10 mL H<sub>2</sub>O and mix well. Pipet 1 mL of this soln into several 50 mL graduates contg 10 mL dil. I soln. Mix well, and det. H<sub>2</sub>O diln necessary to produce *A* value of 0.760 ± 0.02. This is std diln for starch prepn used. Repeat when changing starch source.

**31.158****Determination**

Weigh 5 g sample into 20 mL beaker, dissolve in 10–15 mL

H<sub>2</sub>O and 2.5 mL buffer soln, and transfer to 25 mL vol. flask contg 1.5 mL NaCl soln. Dil. to vol. (Soln must be buffered before addn to NaCl soln.)

Pipet 5 mL starch soln into side arm of reaction tube and 10 mL sample soln into bottom of tube, with care not to mix. Place tube in H<sub>2</sub>O bath 15 min at 40 ± 0.2°; then mix contents by tilting tube back and forth several times. Start stopwatch. At 5 min, remove 1 mL aliquot with 1 mL serological pipet and add rapidly to 10.00 mL dil. I soln in 50 mL graduate. Mix, dil. to previously detd vol., and det. *A* in photometer. Note time from mixing of starch and honey to addn of aliquot to I as reaction time. (Place 1 mL pipet in reaction tube for reuse when later aliquots are taken.) Continue taking 1 mL aliquots at intervals until *A* value of <0.235 is obtained.

The 5 min value gives approximation of end point as follows:

Absorbance	End Point, min
0.7	>25
0.65	20–25
0.6	15–18
0.55	11–13
0.5	9–10
0.45	7–8

**31.159****Calculation**

Plot *A* against time (min) on rectilinear paper; draw straight line thru starting *A* and as many points as possible. From graph, det. time dild reaction-I mixt. reaches *A* of 0.235. Divide 300 by this time to obtain diastase no. (DN).

*Notes:* A 5-min reading is sufficient for approximating end point of sample of high DN (>35) if another value is taken soon enough to obtain *A* of ca 0.20. For accurate results, repeat detn, taking samples each min from start. With samples of low DN, another reading at 10 min will permit prediction of end point by plotting the data. No addnl readings need be taken until within few min of end point. Only 2 such readings are needed. The 5 min value will not accurately predict low DN.

### 31.160 Free, Lactone, and Total Acidity (42) Official Final Action

Dissolve 10 g sample in 75 mL CO<sub>2</sub>-free H<sub>2</sub>O in 250 mL beaker. Stir with mag. stirrer, immerse electrodes of pH meter in soln, and record pH. Titr. with 0.05N NaOH at rate of 5.0 mL/min. Stop addn of NaOH at pH 8.50. Immediately pipet in 10 mL 0.05N NaOH, and without delay back-titr. with 0.05N HCl from 10 mL buret to pH 8.30. Calc. as milliequiv./kg:

Free acidity = (mL 0.05N NaOH from buret - mL blank) × 50/g sample;

Lactone = (10.00 - mL 0.05N HCl from buret) × 50/g sample;

Total acidity = free acidity + lactone.

## MAPLE PRODUCTS (43)

### 31.161 Preparation of Sample—Procedure

#### (a) Maple Sirup

(1) *For solids determination.*—If sample contains no sugar crystals or suspended matter, decant enough clear sirup for detn. If sugar crystals are present, redissolve by heating at ca 50°. If suspended matter is present, filter sample thru cotton wool.

(2) *For other determinations.*—If sugar crystals are present, redissolve by heating. If other sediment is present, distribute it evenly thru sirup by shaking. Transfer ca 100 mL sirup, with its suspended sediment, to casserole or beaker, add ¼ vol. H<sub>2</sub>O, and evap. over flame. When temp. of boiling sirup approaches 104°, draw small amt into thin-wall, ca 1 mL pipet, and cool to room temp. in running H<sub>2</sub>O. Wipe outside of pipet, let possibly dild sirup in point escape, transfer some of remaining sirup to refractometer, and det. solids content of cooled sirup. Repeat operation from time to time until reading is obtained corresponding to 64.5% solids ( $n_{20} = 1.4521$ ), or to such other value as in experience of analyst will give filtered sirup of 65.0% solids. Filter sirup thru filter that will let the 100 mL pass within 5 min and adjust filtrate to 65.0±0.5% solids (refractometric) by thoro mixing with appropriate amt of H<sub>2</sub>O.

#### (b) Maple Sugar and Other Solid or Semisolid Products

(1) *For moisture and solids determination.*—Grind in mortar, if necessary, and mix thoroly.

(2) *For other determinations.*—To prep. sirup, dissolve ca 100 g sample in 150 mL hot H<sub>2</sub>O, boil until temp. approaches 104°, and complete prepn of resulting sirup as in (a)(2), beginning "... draw small amt into thin-wall, ca 1 mL pipet, ..."

### Color Classification (44)—Official Final Action

#### 31.162

#### Apparatus

(a) *Containers.*—See 31.108(a). Internal thickness 1.24 × 1.24" (31.5 mm).

(b) *Comparator.*—See 31.108(b). Only 1 box is required with 3 glass color stds (light amber, medium amber, and dark amber). Place containers, (a), filled with H<sub>2</sub>O behind each glass std.

(c) *Glass stds.*—Use selected colored glasses tested and stdzd by USDA to correspond with color stds for maple sirup.

Complete grading set is available from VirTis Co., Phoenix Precision Instrument Div., Rt 208, Gardiner, NY 12525.

#### 31.163

#### Determination

Proceed as in 31.109. Det. classification as follows: If sample is equal to light amber std in hue, or not as red (*i.e.*, yellower), classify as light amber; if perceptibly redder than light amber

std in hue, but not redder than medium amber std, classify as medium amber; if perceptibly redder than medium amber std, but not redder than dark amber std, classify as dark amber; if redder in hue than dark amber std, classify as "unclassified." Hue (redness or yellowness) is attribute of color in classification.

### Moisture or Solids—Official Final Action

#### 31.164 Maple Sugar

Proceed as in 31.006, or preferably 31.005, using sample prep'd as in 31.161(b)(7).

#### 31.165 Maple Sirup, Maple Cream, etc.

Proceed as in 31.005, 31.007, or 31.011, using prep'd sample. 31.161(a)(7).

#### 31.166 Ash (45)—Official First Action

Prep. sirup as in 31.161(a)(2) or (b)(2). Transfer 5–10 g sample from dropper into tared Pt dish (weigh to nearest 0.1 mg). Add few drops pure olive oil and place in oven 1 hr at 110°. Remove, and heat slowly over low flame or under IR lamp until all H<sub>2</sub>O is expelled and swelling ceases. Ignite in furnace ≥3 hr at 600°. Reweigh and report % ash.

#### 31.167 Soluble and Insoluble Ash—Official Final Action

See 31.015.

#### 31.168 Alkalinity of Soluble Ash—Official Final Action

See 31.016.

#### 31.169 Alkalinity of Insoluble Ash—Official Final Action

See 31.017.

#### 31.170 Alkalinity of Total Ash—Official Final Action

Add alkys of sol. and insol. portions from 31.168 and 31.169.

### Polarization—Official Final Action

#### 31.171 Direct Polarization

See 31.025(a).

#### 31.172 Invert Polarization

(a) *At 20°.*—Proceed as in 31.025(b) or (c) or 31.026 (b) or (c).

(b) *At 87°.*—Proceed as in 31.033.

#### 31.173 Sucrose—Polarimetric Methods—Official Final Action

Proceed as in 31.025 or 31.026, or calc. from results of 31.171 and 31.172(a), using appropriate formula from 31.025 or 31.026.

### Sucrose—Chemical Methods—Official Final Action

#### 31.174 By Reducing Sugars Before and After Inversion

See 31.031.

#### 31.175 Reducing Sugars as Invert Sugar Official Final Action

(a) *Before inversion.*—Proceed as in 31.036 or 31.038, using aliquot of soln used for direct polarization, 31.171. If soln is clarified, only neut. Pb(OAc)<sub>2</sub> soln may be used, and excess of Pb must be removed with dry Na oxalate.

(b) *After inversion.*—Proceed as in 31.036 or 31.038, using aliquot of soln used for invert polarization, 31.172(a). If soln is

clarified, only neut.  $\text{Pb}(\text{OAc})_2$  soln may be used, and excess of Pb must be removed with dry Na oxalate.

### 31.176 Commercial Glucose—Procedure

See 31.032 or 31.033.

#### Lead Number

### 31.177 ★ Canadian Lead Number (Fowler ★ Modification)(46)—Official Final Action

See 29.147–29.148, 10th ed.

#### Winton Lead Number (47)—Official Final Action

### 31.178

#### Reagent

(a) *Basic lead acetate std soln.*—(Caution: See 51.084.) Activate litharge by heating 2.5–3 hr to 650–670° in furnace (cooled product should be lemon color). In 500 mL erlenmeyer provided with reflux condenser, boil 80 g neut.  $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  and 40 g freshly activated litharge with 250 g  $\text{H}_2\text{O}$  45 min. Cool, filter off any residue, and dil. with recently boiled  $\text{H}_2\text{O}$  to density of 1.25 at 20°.

(b) *Dilute basic lead acetate std soln.*—To measured vol. reagent, (a), add 4 vols  $\text{H}_2\text{O}$ , and filter. Conduct blank with each set of detns.

### 31.179

#### Determination of Lead in Blank

Transfer 25 mL dil. std basic  $\text{Pb}(\text{OAc})_2$  soln to 100 mL vol. flask, add few drops HOAc, and dil. to vol. with  $\text{H}_2\text{O}$ . Shake, and det.  $\text{PbSO}_4$  in 10 mL soln as in 31.180. Use of HOAc is imperative to retain all Pb in soln when reagent is dild with  $\text{H}_2\text{O}$ .

### 31.180

#### Determination

Transfer 25 g sample with  $\text{H}_2\text{O}$  to 100 mL vol. flask. Add 25 mL dil. basic  $\text{Pb}(\text{OAc})_2$  std soln and shake. Fill to mark, shake, and let stand  $\geq 3$  hr before filtering. Pipet 10 mL clear filtrate into 250 mL beaker, add 40 mL  $\text{H}_2\text{O}$  and 1 mL  $\text{H}_2\text{SO}_4$ , shake, and add 100 mL alcohol. Let stand overnight, filter on weighed gooch, wash with alcohol, dry in 100° oven, and ignite in furnace at 550°, or over Bunsen burner, placing crucible in larger crucible, applying heat gradually at first, and heating until outside of crucible is barely visible red. Cool and weigh. Subtract wt  $\text{PbSO}_4$  so found from wt  $\text{PbSO}_4$  found in blank, 31.179, and multiply by factor 27.33. Use of this factor gives Pb number directly (without various calcns otherwise required).

#### Conductivity Value (48)—Official Final Action

### 31.181

#### Apparatus

(a) *Conductivity bridge.*—Use any com. available conductivity bridges, which are usually self-contained instruments with 2 external connections, one for connection to power source, usually 110 volt AC, and other to conductivity cell. In addn, some models have means for making adjustment for temp. and cell const. Leeds and Northrup Bridge No. 4961 (replaced by 4866-60) and cell No. 4924 (replaced by 4905-01-44-088) are commonly used and conductivity is read directly, corrected to 20° when in "SC" position. Instruments such as Beckman Instruments, Inc., 89 Commerce Rd, Cedar Grove, NJ 07009, without temp. compensator circuit must have sirup soln at exact temp. specified to be comparative.

Calibrate scale (slide wire) of conductivity bridge by use of external fixed resistor with external leads. This should have

resistance of 1000 ohms which will approx. that of conductivity cell. Attach resistor to bridge connections for conductivity cell and set slide wire to same value as that of resistor. Meter should give 0 reading or response.

(b) *Conductivity cell.*—Made of resistance glass with platinized electrodes firmly fixed and adequately protected from displacement. Cell may be of dipping type, for immersing cell into test soln, or of vessel type, into which soln may be run and subsequently drained.

(c) *Constant temperature bath.*—To maintain or supply  $\text{H}_2\text{O}$  at  $25 \pm 0.1^\circ$  for controlling temp. of test soln and cell.

### 31.182

#### Determination of Cell Constant

Dry 2–3 g KCl at 110° to const wt. Weigh 2 portions dried KCl, one  $0.3728 \pm 0.0002$  g and other  $0.7456 \pm 0.0002$  g, transfer to two 500 mL flasks, and dil. to vol. with  $\text{H}_2\text{O}$  at 20°. These solns will be 0.01 and 0.02M KCl, resp. Transfer portion of 0.01M KCl soln to beaker and adjust temp. to  $25 \pm 0.1^\circ$ .

If conductivity bridge has temp. compensating device, set it at 25°, the temp. of KCl solns. With leads of conductivity cell attached to conductivity bridge, place dipping conductivity cell in 0.01M KCl, taking care to completely immerse electrodes. Adjust slide wire of bridge to give null-point reading. Repeat until 3 successive and concordant slide wire values (ohms resistance) are obtained. Replace KCl soln with fresh portion before making next measurement, taking care to shake adhering drops of liq. from electrodes before immersing them.

Repeat, using 0.02M KCl.

Calc. cell const by multiplying observed resistances (scale readings in ohms) by 141.2 (specific conductivity of 0.01M KCl), and by 276.1 (specific conductivity of 0.02M KCl), resp. Average the 2 results.

### 31.183

#### Determination

Add 70 mL  $\text{H}_2\text{O}$  to 100 mL g-s graduate and fill to vol. with maple sirup to be tested. Stopper, mix thoroly, adjust temp. to  $25 \pm 0.1^\circ$ , and measure resistance of dil. sirup with conductivity cell in same manner as used to calibrate cell. Repeat until 3 concordant observed scale readings (ohms) are obtained. Conductivity value = cell const/ohms.

#### Malic Acid (49)—Official Final Action

### 31.184

#### Apparatus

(a) *Ion exchange tubes.*—Std wall Pyrex glass tubing, 10 (id)  $\times$  300 mm long, with 5 cm capillary tip.

(b) *Spectrophotometer.*—Suitable for measuring A at 390 nm, with matched 1 cm cells or matched test tubes.

### 31.185

#### Reagents

(a) *Ion exchange resins.*—(1) *Cation exchange resin.*—Dowex-50 (60–80 mesh) (currently Dowex 50W-X8 (50–100 mesh)). (2) *Anion exchange resin.*—AG1-X8 (50–100 mesh) (Bio-Rad Labs, 32nd & Griffin Ave, Richmond, CA 94804 or Amberlite CG-400 AR, Type SB (100–200 mesh) (Mallinckrodt).

(b) *Ammonium carbonate soln.*—0.25N. Dissolve 14.26 g  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) *Ammonium carbonate soln.*—1.0N. Dissolve 57.05 g  $(\text{NH}_4)_2\text{CO}_3 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(d) *Sodium carbonate soln.*—1.0N. Dissolve 5.3 g  $\text{Na}_2\text{CO}_3$  in  $\text{H}_2\text{O}$  and dil. to 100 mL.

(e) *Hydrochloric acid soln.*—5%. Dil. 12 mL HCl with 88 mL  $\text{H}_2\text{O}$ .

(f) *2,7-Naphthalenediol soln.*—Dissolve 1 g in 100 mL  $\text{H}_2\text{SO}_4$ .

★ Surplus method—see inside front cover.

(g) *Malic acid std soln.*—Dry Eastman L-malic acid 18 hr at 40°. Dissolve 0.2000 g in 500 mL H<sub>2</sub>O. Dil. known vol. of this soln (ca 10 mL) to 100 mL so that final soln gives *A*, after reaction with color reagent as in detn, of 0.2–0.8.

## 31.186

**Preparation of Ion Exchange Columns**

For each column add enough H<sub>2</sub>O to 10 mL dry resin to make thin slurry and pour slurry into tube contg small plug of glass wool. Let H<sub>2</sub>O drain to level of settled resin and wash with 2 mL portions H<sub>2</sub>O to condition resins. To cation exchange resin (Dowex-50) add three or four 10 mL portions 5% HCl, letting acid drain to top of resin between each addn. Wash resin acid-free with 10 mL portions H<sub>2</sub>O until effluent gives neg. test for chlorides. (Approx. 4 bed vols of H<sub>2</sub>O are required.)

Treat anion exchange resin with three or four 10 mL portions 5% NaOH soln, draining liq. to top of resin between addns. Remove excess alkali with H<sub>2</sub>O by washing with 10 mL portions until effluent gives neg. alkali test with indicator paper. Transform resin into carbonate form by addn of three or four 10 mL portions 1.0*N* Na<sub>2</sub>CO<sub>3</sub> soln. Wash resin carbonate-free with 10 mL portions H<sub>2</sub>O until effluent is neut. to indicator paper. Mount conditioned columns vertically with cation resin column directly above anion resin column, connecting tubes with 1-hole rubber stopper mounted in top of anion column. No stopcocks are required; close packing of fine resins prevents liq. from draining below surface of resins. Any portion of resin that becomes dry will be inactivated.

## 31.187

**Separation of Malic Acid**

Transfer ca 10 mL sirup sample to tared 100 mL vol. flask and weigh to  $\pm 0.2$  mg. Dil. to vol. with H<sub>2</sub>O and transfer aliquot contg 6–20 mg malic acid (ca 15 mL) to cation exchange resin and let eluate pass onto anion exchange resin. Wash cation resin (upper column) with three 10 mL portions H<sub>2</sub>O, again letting eluate pass directly onto anion resin. Remove upper column and wash anion resin column with three 10 mL portions H<sub>2</sub>O to remove sugars and any loosely held acids present that might interfere with test. Elute column with five 10 mL portions 0.25*N* (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> to quant. remove all glycolic, glyceric, or lactic acids possibly present in original test soln. Elute malic acid from anion resin with five 10 mL portions 1*N* (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>; collect 45–48 mL eluate in 250 mL vol. flask, and dil. to vol. with H<sub>2</sub>O.

## 31.188

**Determination**

Transfer 1 mL malic acid-(NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> eluate to 18 × 150 mm culture tube and slowly add 6 mL 96% H<sub>2</sub>SO<sub>4</sub> from buret, adding first 2 mL down walls of tube to avoid excessive evolution of CO<sub>2</sub>. Add 0.1 mL 2,7-naphthalenediol soln and mix thoroly. Cap tubes with metal culture tube closures and heat in boiling H<sub>2</sub>O bath (deep fat fryer is satisfactory) 25 min to develop color. Cool tubes, and measure *A* of colored solns within 30 min in 1 cm cell at 390 nm against blank of 1 mL H<sub>2</sub>O, 6 mL H<sub>2</sub>SO<sub>4</sub>, and 0.1 mL reagent also heated 25 min in boiling H<sub>2</sub>O bath.

Color developed follows Beer's law in which  $a = A/Cb$ , where *a* is absorptivity, *C* is concn in mg/mL, and *b* is cell thickness. Absorptivity may vary from day to day because of differences in blank; therefore, *a* must be established daily with duplicate portions of fresh std malic acid soln. Calc. *a* from *A* at 390 nm of colored soln resulting from reaction of soln of std malic acid and color reagent. Calc. amt of malic acid in sample from:  $C = (A/ab) \times \text{diln factor}$ . Express value for malic acid in maple sirup in terms of std density (65.5° Brix) sirup.

**Formaldehyde (50)—Official Final Action**

## 31.189

**Apparatus**

(a) *Distillation apparatus.*—30 mL micro Kjeldahl flask, with  $\frac{1}{8}$  19/38 joint and 10 cm H<sub>2</sub>O-cooled West condenser with  $\frac{1}{8}$  19/38 inner joint bent at 90° angle. Prep. permanent insulation of bent portion of condenser by wrapping with  $\frac{1}{8}$ " diam. asbestos cord from  $\frac{1}{8}$  joint to H<sub>2</sub>O jacket. Install adjustable flask heater equipped with conical porcelain coil element and hand-controlable rheostat placed on underside (Cenco Instrument Corp. No. 16530-1, or equiv.).

(b) *Spectrophotometer.*—Suitable for measuring *A* at 415 nm; with matched 1 cm cells or matched test tubes.

## 31.190

**Reagents**

(a) *Nash's Reagent "B".*—Dissolve 150 g NH<sub>4</sub>OAc, 3 mL HOAc, and 2 mL acetylacetone in 200–300 mL H<sub>2</sub>O in 1 L flask and dil. to vol.

(b) *Formaldehyde.*—Approx. 37% by wt. Assay by 6.349.

## 31.191

**Preparation of Standard Solutions**

(a) *Stock soln.*—1000 ppm. Weigh 5.35 g 37.4% CH<sub>2</sub>O soln (for other concns, g CH<sub>2</sub>O soln required = 200/% CH<sub>2</sub>O) into 2 L vol. flask contg H<sub>2</sub>O and dil. to vol. with H<sub>2</sub>O.

(b) *Soln B.*—50 ppm. Pipet 10 mL *stock soln* into 200 mL vol. flask and dil. to vol. with H<sub>2</sub>O.

(c) *Soln C.*—100 ppm. Pipet 10 mL *stock soln* into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O.

(d) *Soln D.*—200 ppm. Pipet 10 mL *stock soln* into 50 mL vol. flask and dil. to vol. with H<sub>2</sub>O.

(e) *Formaldehyde std solns.*—Prep. 1, 2, and 4 ppm std solns by pipetting 10 mL *Solns B, C, and D*, resp., into 500 g sirup and stirring mech. 15 min.

## 31.192

**Determination**

Weigh  $20 \pm 0.20$  g sample into tared 30 mL micro Kjeldahl flask and insulate flask neck with asbestos cord as in 31.189(a) from base of  $\frac{1}{8}$  joint down to body of flask. (This insulation is temporary; repeat after each washing and weighing.) Add 2 drops antifoam agent, and connect West condenser. Mount app., adjusting slope of condenser at 45° angle, with flask bottom centered in conical cavity and at such ht that sirup level in flask is even with top plate of heater, without touching hot element at any point; see Fig. 31.03. Heat flask with heater, previously

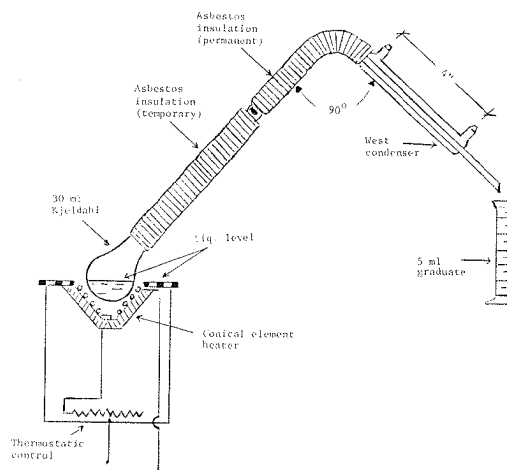

FIG. 31.03—Distillation apparatus for determining formaldehyde in maple sirup

adjusted with control knob in such position that exactly 3 mL H<sub>2</sub>O is distd from sirup in 12–14 min. Collect 3 mL distillate in 5 mL graduate with funnel top. Using transfer pipets, place 1 mL distillate in 13 mm id test tube, and add 1 mL H<sub>2</sub>O and 2 mL Nash's reagent. Heat 30 min in H<sub>2</sub>O bath at 37±1° to develop color. Transfer colored soln to 1 cm cell and measure *A* at 415 nm against H<sub>2</sub>O.

**31.193****Blanks**

To det. *A* due to reagents, substitute 1 mL H<sub>2</sub>O (from same source as used in detn) for 1 mL sample distillate. Subtract *A* of blank from that for sample to obtain *A* due to CH<sub>2</sub>O. Or, as simpler operation, measure *A* of sample with instrument adjusted to 0 *A* for blank.

Obtain concn of CH<sub>2</sub>O in sirup from *A*, using std curve.

**31.194****Preparation of Standard Curve**

Construct std curve by plotting *A* obtained for sirups contg 1, 2, and 4 ppm CH<sub>2</sub>O against concn of added CH<sub>2</sub>O in ppm.

Straight line relationship is obtained for std curve. Project this line to *Y* axis (*A*); *Y* intercept indicates blank for sirup. Since sirup used to construct curve from *A* values may be atypical, draw and use parallel curve with 0 intercept. Correct ppm values obtained from this curve for av. sirup blank (ca 0.9 ppm).

**Yeast Count (57)—Official Final Action****31.195****Apparatus**

(a) *Water bath*.—Const temp., capable of holding H<sub>2</sub>O temp. at 27±1°.

(b) *Electric stirrer*.—Non-aerating (Kraft Apparatus, Inc., 402 Sagamore Ave, Mineola, NY 11501, Model S-25-25A, or equiv.).

(c) *Beakers*.—Tall-form, 300 and 500 mL. Cover with Al foil before sterilizing.

(d) *Hypodermic syringe*.—5 mL (Luer-Lok), or equiv., with hypodermic needle, 14 gage (Luer-Lok), 2" long.

(e) *Dilution bottles*.—160 mL, 45 × 140 mm.

(f) *Serological pipets*.—To deliver 1.0 mL with 0.1 mL graduations.

(g) *Petri dishes*.—100 × 15 mm.

Sterilize apparatus (c), (d), (f), and (g) 1 hr in hot air oven at 160°. Items (f) and (g) do not have to be sterilized when obtained as "single use" sterile plastic.

**31.196****Culture Medium**

*Wort agar culture medium*.—Boil 15.00 g malt ext, 0.78 g peptone, 2.75 g dextrin, 2.35 g glycerol, 1.00 g K<sub>2</sub>HPO<sub>4</sub>, 1.00 g NH<sub>4</sub>Cl, 12.75 g maltose, and 20.00 g agar in 1 L H<sub>2</sub>O until dissolved. Autoclave 15 min at 121°.

**31.197****Reagents**

(a) *Phosphate buffer stock soln*.—pH 7.2, 0.25M. See 4.023(e).

(b) *Phosphate buffer dilution water*.—See 4.023(f).

(c) *Hypochlorite germicide soln*.—200 ppm available Cl. Add 5 mL 5.25% NaClO soln to 1 gal. (3.8 L) H<sub>2</sub>O.

**31.198****Preparation of Sample Culture**

Sterilize stirrer head by submerging in 400 mL germicide soln in 500 mL tall-form beaker ≥10 min. Rinse by immersing in three 450 mL portions sterile H<sub>2</sub>O in 500 mL tall-form beakers.

Warm bottle contg sirup to 80°F (26.7°) in H<sub>2</sub>O bath set at 80±1.0°F. Transfer sirup to 300 mL sterile tallform beaker, place in 80°F constant temp. H<sub>2</sub>O bath, and insert sterilized stirrer. Position stirrer near bottom of beaker and off center to prevent

forming vortex. Cover with Al foil while stirring. Stir sirup 10 min at ca 500 rpm. If gas bubbles form, let sirup stand in H<sub>2</sub>O bath until gas bubbles rise to surface.

Assemble sterile 14 gage needle and 5 mL syringe. Remove cover from sirup sample and with needle held ≥2.5 cm below surface of sirup, slowly draw 5.5–6.0 mL sirup into syringe. Invert syringe, holding needle vertically. Wipe excess sirup from needle with gauze pad wetted with alcohol. Holding pad around tip of needle, bring syringe plunger exactly to 5.0 mL graduation, expelling excess sirup and any air bubbles into sterile pad.

Make 10<sup>-1</sup> diln of sirup by expelling 5 mL sirup completely from syringe into 45 mL sterile phosphate buffer diln blank, (b). Shake inoculated diln blank vigorously 10 sec, transfer 1 mL to petri dish with 1 mL pipet for 10<sup>-1</sup> diln plate, and transfer 0.1 mL 10<sup>-1</sup> diln with 1 mL pipet to petri dish for 10<sup>-2</sup> diln plate. Transfer 1 mL of 10<sup>-1</sup> diln to 99 mL sterile diln blank, (b), for 10<sup>-3</sup> diln. Prep. 10<sup>-3</sup> and 10<sup>-4</sup> diln plates by using 1 and 0.1 mL vol. 10<sup>-3</sup> sirup diln, resp. Transfer 1 mL 10<sup>-3</sup> diln to 99 mL sterile diln blank, (b), to make 10<sup>-5</sup> sirup diln. Prep. 10<sup>-5</sup> and 10<sup>-6</sup> diln plates by using 1 and 0.1 mL 10<sup>-5</sup> diln, resp.

Pour 10–12 mL liquefied wort agar at 42–44° into each plate and mix with dild culture. After agar has solidified, invert plates and incubate 5 days at 21–25°. Count plates on 5th day, using Quebec Colony Counter, or equiv.

**Bacterial Population of Maple Sap (52)****Official Final Action****31.199****Principle**

Resazurin is reduced to resorufin in direct proportion to bacterial action, with color change from purple to pink. Method permits rapid estimation of bacterial populations >1 × 10<sup>6</sup> cells/mL in maple sap.

**31.200****Apparatus**

(a) *Serological pipets*.—To deliver 1 and 10 mL, with 1.0 mL graduations; sterilized.

(b) *Test tubes*.—150 × 16 mm, screw-top with molded plastic caps; sterilized.

(c) *Incubator or water bath with opaque cover*.—Constant temp., capable of maintaining 37.5±0.5°.

(d) *Bottles*.—200 mL amber, g-s.

**31.201****Reagents**

(a) *Nonfat milk soln*.—Dissolve 100 g instant nonfat dry milk in 500 mL H<sub>2</sub>O. Autoclave 15 min at 121°.

(b) *Resazurin dye*.—Autoclave 200 mL H<sub>2</sub>O in amber glass bottle 15 min at 121°. Using sterile forceps, add 1 std (certified by Biological Stain Commission) resazurin dye tablet (Allied Chemical Corp.) and shake to completely dissolve dye before H<sub>2</sub>O cools. Store in cool, dark place. Prep. weekly.

(c) *Sterile maple sap control*.—Place 10 mL raw sap in test tube and autoclave 15 min at 121°.

**31.202****Technic**

To sterile test tube, transfer 1 mL nonfat milk soln and 10 mL sample. Prep. control tube using 1 mL nonfat milk soln and 10 mL sterile maple sap control. Mix by capping and inverting tubes. Incubate 30 min at 37.5°, using incubator, 31.200(c). Remove tubes and, with sterile pipet, add 1 mL resazurin dye soln to each. Cap tubes, invert to mix thoroly, and incubate at 37.5°. Do not agitate tube before reading. Examine tube for color change to Munsell std bluish purple (new designation 4-P Matte) 2.5 P6/8 (Munsell Color Co., Inc., 2441 North Calvert St., Baltimore, MD 21218) end point at 0.5, 1, 2, 3, 4, and 5 hr. Color

control should match Munsell std 7.5 PB6/10 and should remain stable for duration of test. Calc. bacterial cell population from:  $\log Y = 7.84 - 0.587 X$ , where  $Y$  = bacterial count, cells/mL, and  $X$  = time for color development in hr.

## SUGAR BEETS

### Sucrose

#### 31.203 Hot Water Digestion Method I (53) Official First Action

(Caution: See 51.015.)

Pass sample (usually in form of cossettes) thru meat grinder fitted with plate having 6 mm ( $\frac{1}{4}$ ") perforations and mix thoroly. Weigh 26 g prepd sample and rinse into 201.0 mL Kohlrausch flask, using ca 100 mL  $H_2O$ . Place flask under good vac. 5–10 min to remove air, carefully avoiding mech. loss when vac. is first applied. Add  $H_2O$  to ca 175 mL, and digest in  $H_2O$  bath at 80°, supporting flask so that body is entirely immersed but is not in contact with heating element. Remove flask 2 or 3 times during digestion, swirl contents, and after each agitation wash down pulp adhering to walls of flask with little  $H_2O$  at 80°.

After exactly 30 min digestion, fill flask to within 2–5 mL of mark with  $H_2O$  at 80° and continue digestion exactly 10 min longer. Cool to room temp. in  $H_2O$  bath. Add 6 mL basic  $Pb(OAc)_2$  soln, 31.021(a), and  $H_2O$  to fill to mark. (Previous addns of  $H_2O$  and reagents should be so adjusted that  $\leq 4$  mL  $H_2O$  is required to dil. to vol.) Mix well by shaking, let stand 5 min, shake again, and filter. Let stand near saccharimeter at least 5 min, and polarize in 400 mm glass tube. If vol. adjustment and polariscopic observation are made at 20°, reading gives % sucrose directly; if at other temps, apply formula in 31.022(a).

*Notes:* The 1 mL >200 mL vol. is the detd vol. of marc for beets grown in Colorado and neighboring states. It should be detd for other localities. Beets of abnormally low purity may require 8–10 mL basic  $Pb(OAc)_2$  soln for clarification. If foaming causes trouble, flask may be put under vac. second time after cooling, or few drops ether or 1 drop *amyl alcohol* may be added before soln is dild to vol.

#### 31.204 Hot Water Digestion Method II (54) Official First Action

Use Ni-plated sheet Fe vessels, 11 cm high, 6 cm body diam., and 4 cm mouth diam.; use stoppers covered with Sn foil to fit.

Weigh 26 g prepd beet pulp, 31.203, on watch glass (small enough to go into neck of beaker) and transfer to metal beaker; add 177 mL dil. basic  $Pb(OAc)_2$  soln (5 parts basic  $Pb(OAc)_2$  soln, 31.021(a), to 100 parts  $H_2O$ ); shake, and stopper lightly. Submerge beaker in  $H_2O$  bath 30 min at 75–80°, shaking intermittently. When all air is expelled (generally after 5 min), tighten stopper. After 30 min, shake, cool to std temp., filter, add drop HOAc to filtrate, and polarize in 400 mm tube. Reading is % sugar in beet pulp.

## STARCH CONVERSION PRODUCTS

#### 31.205 Preparation of Sample—Official First Action

See 31.001.

### Moisture—Official First Action

#### 31.206 Method I

(Applicable to refined corn sugars)

See 31.005.

#### 31.207

#### ★ Method II (55) ★

(Applicable to corn sirups and crude corn sugars)

Vac. oven drying of sample absorbed on filter paper. See 31.193–31.194, 12th ed.

### Method III (56)

(Applicable to corn sirups and crude corn sugars)

#### 31.208

#### Material and Apparatus

(a) *Diatomaceous earth*.—Filter-Cel, or equiv. Preferably anal. grade. If com. grade is used, wash with HCl, then with  $H_2O$  to remove acid, and dry in oven at ca 105°. (Material should give neg. test for acid when moistened.)

(b) *Moisture dish*.—Al dish 25 mm high  $\times$  75 mm diam., with cover.

(c) *Pestle*.—Flat-end glass stirring rod ca 60 mm long.

#### 31.209

#### Determination

Place 10 g Filter-Cel in moisture dish contg pestle and dry to const wt. Weigh ca 5 g corn sirup or sugar in nickel scoop, dil. with ca 5 mL  $H_2O$ , and add to Filter-Cel. Wash scoop with three 2 mL portions  $H_2O$  and add washings to Filter-Cel. Thoroly incorporate soln with Filter-Cel by means of pestle, yielding damp workable mass. Dry to const wt in vac. oven at 100° for corn sirup or 70° for crude corn sugars.

### Method IV (Corn Industries Research Foundation Method) (57)—Official Final Action

(Applicable to corn (glucose) sirups)

#### 31.210

#### Material and Apparatus

(a) *Diatomaceous earth*.—Hyflo Super-Cel only. Wash large portion on buchner with HCl (1+1000) until effluent is acid to litmus. Then wash with  $H_2O$  until pH of effluent is  $\geq 4$ . Dry washed diat. earth in oven overnight at 105° and keep in closed container.

(b) *Moisture dish*.—Modify small A1 desiccator (Desiccator, Fisher Scientific Co., or equiv.) 76 mm high  $\times$  90 mm diam., with cover, to serve as container. Remove plastic handle from cover and close opening with rivet; also remove inner tray.

(c) *Stirrers*.—Pyrex test tubes, 100  $\times$  13 mm. Make extensions for test tubes from stainless steel rods, 180  $\times$  8 mm. Fit rods near one end with two rubber rings so spaced on rod that when it is inserted into test tube, snug fit is obtained near top and bottom of test tube.

(d) *Vacuum oven and vacuum pump*.—Capable of maintaining oven pressure of  $\leq 3.3$  kPa (25 mm Hg). Dry oven air by passing first thru gas scrubber contg  $H_2SO_4$  and then thru anhyd.  $CaSO_4$  (Drierite, or equiv.) in drying tower.

#### 31.211

#### Determination

Add 30 g previously dried diat. earth, (a), to moisture dish. Prep. tare dish with slightly less diat. earth than sample dishes. Place stirrers, (c), without extension rods in dishes. Dry sample dishes and covers, with covers off dishes, in vac. oven 5 hr at 100°, bleeding air thru drying train. Slowly release vac., remove dishes and covers from oven, quickly cover dishes, place in desiccator, and cool to room temp. Release covers of sample dishes and tare momentarily before weighing. Place tare on right hand pan of two-pan anal. balance and sample dish on left

★ Surplus method—see inside front cover.

hand pan. Add wts to tare until balance is obtained and record wt to nearest mg. If using single pan anal. balance, also weigh tare with sample dishes. Use any change in wt of tare which occurs between initial and final weighing of tare to correct final wt of sample dishes.

Accurately weigh 7–10 g sample (4–7 g dry substance) in 45 mL (40 × 50 mm) weighing bottle with  $\frac{1}{2}$  cap style stopper. Add 10 mL warm H<sub>2</sub>O and stir thoroly with small glass rod. Pour dild sample onto diat. earth in sample dish and complete quant. transfer of sample with three 5 mL portions of warm H<sub>2</sub>O. Insert steel rod extension into stirring tube in sample dish and stir until sample is homogeneously dispersed thruout diat. earth. Remove rod, leaving stirring tube in dish, and place tare and sample dishes (with covers off) in vac. oven at 70° for corn sirups of >58 Dextrose Equivalent (D.E., reducing sugars as dextrose, dry basis), and at 100° for corn sirups of ≤58 D.E. Dry all fructose-contg sirups at 70°. Dry sample dishes in vac. oven 5 hr. Remove sample dishes from oven, insert stirring rod extension into stirring tube, and rework diat. earth until fine powder free of lumps is obtained. Return sample dishes to oven and heat 16 addnl hr under vac. Shut off vac. and slowly fill oven with air drawn thru drying train. Open oven, quickly cover tare and sample dishes, and place covered dishes in desiccator. Cool sample dishes and tare to room temp. and weigh as before.

#### Dry Substance—Official First Action

##### Method I—By Hydrometer (58)

#### 31.212

#### Apparatus

(a) *Water bath*.—Insulated H<sub>2</sub>O bath with stirrer and thermostatic control, held at 60°.

(b) *Cylinders*.—Pyrex, 15 × 2¼", without lip.

(c) *Stopper seal*.—Consisting of 2 rubber stoppers that fit snugly into cylinder, sepd on metal rod by ca 8 cm. Rod is fixed in lower stopper but does not extend thru it. Top stopper is free to move on rod, altho tight enough to maintain predetd position, preventing evapn during heating.

(d) *Baumé hydrometers*.—Streamlined type, modulus 145, stdzd at 15.56° with range 35–45° Bé in 0.1° Bé; length over-all 12–13"; body diam. 0.77–0.79"; scale length 147–155 mm.

#### 31.213

#### Determination

Fill cylinder with sirup to within 10 cm of top, taking care that sides are free from sirup. Seal cylinder with stopper seal, placing bottom stopper within 1 cm of sirup surface and closing cylinder with top stopper. Immerse cylinder in H<sub>2</sub>O bath at 60° (140°F) so that level of sirup is ca 5 cm below level of H<sub>2</sub>O. Immerse hydrometer in H<sub>2</sub>O bath. When sirup in cylinder is free of air and has reached temp. of bath (ca 90 min), raise cylinder until surface of sirup is at eye level. Remove stopper seal and insert previously dried hydrometer. After ca 10 min, read hydrometer. To obtain com. Baumé, add 1° Bé. to observed reading of hydrometer:

$$\text{Com. Baumé} = \text{Bé. (140°F/60°F)} + 1^\circ \text{Bé.}$$

Det. corresponding dry substance from Table 31:09.

#### 31.214 Method II—By Refractometer (59)

(Applicable only to liq. samples contg no undissolved solids)

Det. refractometer reading at 45°. Circulate H<sub>2</sub>O thru jackets of refractometer long enough to let temp. of prisms and of sample reach equilibrium, continuing circulation during observation, and taking care that temp. is held const. From Table 31:10 obtain com. Baumé corresponding to observed refractive index. From Table 31:09 obtain corresponding dry substance.

Table 31:09 Commercial Table for Dry Substance in Corn Sirup and Corn Sugar Sirup

(Commercial Baumé = Bé. 140°F/60°F + 1° Bé.)

**31.215 Ash—Official First Action**

(For most corn sugars and sirups it is unnecessary to re-ash.)

See 31.012.

**31.216 Sulfated Ash—Official First Action**

See 31.014. For most corn sirups and corn sugars, only a single sulfation is necessary

**31.217 Acidity—Official First Action**

Weigh 50 g sample, dissolve in 200 mL H<sub>2</sub>O, and titr. with 0.1N NaOH, using phthln, to faint pink end point (pH 8.3). Calc. acidity as HCl.

**31.218 Hydrogen-Ion Activity—Official First Action**

Prep. soln of sample contg 40% total solids and det. pH potentiometrically. (Buffer capacity of product is normally such that no special provision need be made with regard to H<sub>2</sub>O used for diln. If glass electrode is used, stdze against ref. buffer within 1.0 of detd pH.)

**31.219 Nitrogen—Official First Action**

See 2.057.

**31.220 Total Reducing Sugars—Official First Action**

(a) *Lane-Eynon General Volumetric Method.*—See 31.036. Use glucose as std.

(b) *Munson-Walker General Method.*—See 31.038. Prep diln contg ca 1% reducing sugar.

**Glucose by Steinhoff Methods—Official First Action****31.221 ★ Zerban-Sattler Modification (60) ★**

Iodimetric titrn of pptd Cu<sub>2</sub>O. See 31.206–31.207, 12th ed.

**31.222 ★ Sichert-Bleyer Modification (61) ★**

Pptd Cu<sub>2</sub>O dissolved in FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub> and excess titrd with KMnO<sub>4</sub>. See 31.208–31.209, 12th ed.

**Glucose by Glucose Oxidase Method (62)  
Official Final Action****31.223 Principle**

Glucose is enzymatically oxidized with glucose oxidase to form H<sub>2</sub>O<sub>2</sub>, which reacts with a dye in presence of peroxidase to give stable colored product proportional to glucose concn.

**31.224 Reagents**

(a) *Glucose test soln.*—Consists of (1) *Glucose oxidase.*—1000 glucose oxidase units/mL; purified (Miles Laboratories, Inc., or equiv.). (2) *Horseradish peroxidase.*—Available from Worthington Biochemical Co., Freehold, NJ 07728. (3) *Chromogen.*—*o*-Dianisidine.2HCl. (4) *Acetate buffer soln.*—pH 5.5, 0.1M. Dissolve 13.608 g NaOAc.3H<sub>2</sub>O and dil. to 1 L with H<sub>2</sub>O. Add 2.7 mL HOAc and adjust pH with NaOAc or HOAc, if necessary.

Dissolve 40 mg chromogen, 40 mg horseradish peroxidase, and 0.4 mL glucose oxidase in 0.1M acetate buffer and dil. to 100 mL with buffer soln.

(b) *Glucose std soln.*—1 mg/mL. Dissolve 1.000 g NBS D-glucose, SRM 917 (previously dried 4 hr at 70° under vac.) in

H<sub>2</sub>O and dil. to 1 L in vol. flask. Mix and let stand 2 hr to permit mutarotation to occur. Prep. fresh on day of use.

**31.225 Apparatus**

(a) *Spectrophotometer.*—Suitable for measuring A at 540 nm, with matching 1 cm cells.

(b) *Water bath.*—Capable of maintaining temp. at 30±1°.

**31.226 Preparation of Standard Curve**

Pipet 1, 2, 3, and 4 mL aliquots std glucose soln into sep. 50 mL vol. flasks and dil. to vol. with H<sub>2</sub>O. Mix and pipet 2 mL of each dild std into 18 × 150 mm test tubes (0.04, 0.08, 0.12, 0.16 mg glucose). Use 2 mL H<sub>2</sub>O as blank. Place all tubes in 30° H<sub>2</sub>O bath 5 min. At 0 time, start reaction by adding 1.0 mL glucose test soln to first tube. Allow 30–60 sec interval between enzyme addn to each subsequent tube. Mix tubes and let react exactly 30 min at 30°. Immediately stop reaction (30–60 sec intervals) by pipetting 10 mL H<sub>2</sub>SO<sub>4</sub> (1+3) into each tube. Mix, cool to room temp., and measure A against reagent blank at 540 nm, using 1 cm cells. Plot A at 540 nm against mg glucose on linear coordinate paper.

**31.227 Determination**

Weigh 1–5 g sirup sample to nearest 0.1 mg, using weighing bottle to prevent moisture loss during weighing. Dil. successively with H<sub>2</sub>O to concn of 2.5–7.5 mg glucose/100 mL. Pipet 2 mL dild sample into 18 × 150 mm test tube. Proceed as in 31.226, beginning "Place all tubes in 30° H<sub>2</sub>O bath 5 min." Det. mg glucose from std curve and calc. % glucose in sample.

For results on dry substance basis, det. sample dry substance as in 31.212–31.213 or 31.214.

**Saccharides by Liquid Chromatography (63)****Corn Industries Research Foundation Method  
Official First Action**

(Applicable to corn (glucose) sirup)

**31.228 Principle**

Corn sirup soln is passed thru cation exchange column. Sugars are sep'd by mol. exclusion and selective adsorption, and detected with differential refractometer. Peaks are quantitated against appropriate std with digital computing integrator. Psicose, fructose, dextrose, maltulose, other disaccharides (DP<sub>2</sub>), DP<sub>3</sub>, DP<sub>4</sub>, etc. are detd in corn sirup with 50W-X4 resin. Alternative Q15-S column is suitable for detn of psicose, fructose, dextrose, total DP<sub>2</sub>, DP<sub>3</sub>, and DP<sub>4</sub>+

**31.229 Apparatus**

(a) *Liquid chromatograph.*—Waters Associates Model 201 equipped with Model 6000 pump and Model R-401 refractive index detector (Waters Associates, Inc.), or equiv.

(b) *Recorder.*—Hewlett-Packard Model 7100B recorder with Model 17505A input module, or equiv.

(c) *Digital integrator.*—Spectra-Physics Autolab System I Computing Integrator with calcn capability, used according to manufacturer's "Method 1" (Spectra-Physics, 2905 Stender Way, Santa Clara, CA 95051), or equiv.

(d) *Circulating bath.*—45±0.005°. Haake Model FK (Haake, Inc., 244 Saddle River Rd, Saddle Brook, NJ 07662), or equiv.

(e) *Circulating bath.*—78±0.05°. Haake Model FS, or equiv. Dow Corning 200, 5cS viscosity silicone oil may be used as bath medium.

★ Surplus method—see inside front cover.

(f) *Syringe*.—100  $\mu$ L Precision Sampling, Series B, Model 01-9264, PRESSURE-LOK (Precision Sampling Corp., 8275 West El Cajon, Baton Rouge, LA 70895), or equiv.

(g) *HPLC column*.—610  $\times$  7 (id) mm (24  $\times$   $\frac{3}{8}$ "(od)) stainless steel column packed with Aminex 50W-X4, 20–30  $\mu$ , Ca resin (or, alternatively, Aminex Q15-S, 19–25  $\mu$ , Ca resin), and fitted with Waters Associates Model 98764 column temp. control block and  $\frac{3}{8}$ ", 10  $\mu$  frit, end fittings.

### 31.230

#### Reagents

(a) *Mobile phase*.—Degassed H<sub>2</sub>O, filtered thru 0.22  $\mu$  Millipore filter before use. Keep at ca 65° and stir slowly on hot plate-stirrer to remove dissolved gas.

(b) *Column packing*.—Aminex 50W-X4, 20–30  $\mu$ , or Q15-S, 19–25  $\mu$ , Ca form resin. Slurry required amt of Aminex 50W-X4, H form, or Q15-S, Na form cation exchange resin (Bio-Rad Laboratories) with H<sub>2</sub>O, transfer to 350 mL medium porosity fritted glass funnel, and remove H<sub>2</sub>O with vac. Wash each 10 g resin with 300 mL filtered (Whatman No. 4 paper, or equiv.) 0.3M Ca(OAc)<sub>2</sub> soln adjusted to pH 6.2 with HOAc. Wash each 10 g resin with 200 mL H<sub>2</sub>O. Remove H<sub>2</sub>O from treated resin with vac. and store in nonactinic bottle at room temp.

(c) *Mixed ion exchange resin*.—Exhaust (2 L 1.5N NaOH) and regenerate (2 L 1.5N HCl) ca 600 mL bed vol. Duolite C-3 (Diamond Shamrock Chemical Co, PO Box 829, Redwood City, CA 94064) cation resin. Repeat twice. Exhaust (2 L 1.5N HCl) and regenerate (once each with 2 L 1.5N NaOH, and 2 L 2N Na<sub>2</sub>CO<sub>3</sub>) ca 600 mL bed vol. Duolite ES-561 weak base anion exchange resin. Repeat twice. Wash final regenerated resins with H<sub>2</sub>O to pH ranges of 4–5 (C-3) and 6–7 (ES-461). Air dry resins, combine equal wts of each, and mix. Avoid strong base resins which may promote alk. isomerization of sample.

(d) *Carbohydrate standards*.—Glucose (NBS); fructose (Pfanzstiehl Laboratories, Inc., 1219 Glen Rock Ave., Waukegan, IL 60085); maltose-H<sub>2</sub>O, Grade HHH (Hayashibara Biochemical Laboratories, Inc., 2–3, 1-CHOME, Shimoishii, Okayama, Japan); maltotriose (United States Biochemical Corp., 21000 Miles Pkwy, Cleveland, OH 44128); acid converted 42 Dextrose Equivalent (DE) corn sirup (available from member companies of Corn Refiners Association, Inc., (CRA), 1001 Connecticut Ave NW, Washington, DC 20036); psicose (Carb. Res. 16, 383(1971)); maltulose (Cereal Science Today 17, 180(1972)).

Est. corn sirup composition by detg level of each saccharide shown for given DE in CRA, Inc. Critical Data Tables, pp. 8–13. Det. DE as in 31.036 and 31.209. Purity of given sugar may be detd by normalized LC analysis.

(e) *Mixed sugar standard*.—Prep. std sugar soln to contain ca 3 g dry carbohydrate substance/25 mL. Make dry basis % of each std sugar equiv. to level in typical sample of given type. Use 42 DE corn sirup to represent DP<sub>4+</sub> fraction, adding dry wts of mono-, di-, and trisaccharide from 42 DE sirup to dry wts of pure glucose, maltose, and maltotriose used for std prepn. Add appropriate dry wt of each std sugar to tared 50 mL beaker. Record wt to fifth place. Add 20 mL H<sub>2</sub>O, cover, and place on steam bath to dissolve. Transfer quant. to 25 mL vol. flask, dil. to vol., and mix. Add several drops toluene as preservative. Store at room temp. Avoid toluene layer when drawing up soln for std injection. Compute dry basis concn of each sugar:

$$\begin{aligned} \% \text{ sugar, dry basis} = & \text{wt sugar} \times 100 / (\text{wt glucose} + a + b) \\ & + (\text{wt fructose} + c) + [(\text{wt maltose} \times 0.94) + d + e] \\ & + [(\text{wt maltotriose} \times 0.94) + f + g + h] + \text{wt DP}_{4+}, \end{aligned}$$

where maltose and maltotriose wts are multiplied by 0.94 to account for H<sub>2</sub>O of hydration and trace impurities; *a* and *b* = wt glucose from 42 DE sirup and maltulose; *c* = wt fructose from maltulose; *d* and *e* = wts of DP<sub>2</sub> from 42 DE sirup and maltulose;

and *f*, *g* and *h* = DP<sub>3</sub> wts from 42 DE sirup, maltulose, and maltose.

### 31.231

#### Preparation of Column

Place empty column vertically, and attach 380  $\times$  7.7 (id) mm (15  $\times$   $\frac{3}{8}$ " (od)) stainless steel precolumn, using  $\frac{3}{8}$ " union. Attach end fitting to bottom of column and vac. line to end fitting. Attach open-ended vessel (ca 500 mL) to precolumn with Tygon tubing and secure vessel in same plane as column. Slowly fill column, precolumn, and ca  $\frac{1}{3}$  of vessel with H<sub>2</sub>O. Slurry ca 50 mL bed vol. of resin and add to vessel, using vac. Bring column to 78°. Pull vac. on column until resin level in vessel is const. Discontinue vac., disconnect vessel from precolumn, and pump solv. through precolumn and column at 0.5 mL/min (0.7 mL/min for Q15-S resin) overnight. Disconnect end fitting from precolumn and precolumn from column. Fill end fitting with ca 5 mm resin and attach to column. Cap end with fittings when storing column.

### 31.232

#### Operating Conditions

Flow rate 0.4 mL/min (0.6 mL/min for Q15-S resin); column temp. 78°; detector temp. 45°; detector attenuation 8 $\times$ ; detector output 10 mv; recorder attenuation 1 $\times$ , recorder range 10 mv; chart speed 2 in./hr. Program integrator to obtain trapezoidal baseline correction for each peak and to prevent erroneous baseline at valley point between fused peaks or on plateau created by fused peak cluster.

### 31.233

#### Standardization

Inject 30  $\mu$ L (ca 3.5 mg solids) of std soln. Integrate std sugar peaks in normalized mode. Sum DP<sub>4+</sub> fractions obtained from normalized printout to obtain DP<sub>4+</sub> normalized response. Divide known dry basis concn by normalized response for each component to obtain ratios. Divide each component ratio by glucose ratio to obtain System I KF values (calibration factors). Program component KF values in System I, 31.229(c), using Method 1 and glucose as ref. (KF<sub>glucose</sub> = 1). Enter DP<sub>3</sub> KF at both DP<sub>3</sub> retention time and at time 100 sec less than DP<sub>3</sub> time, to provide KF for panose, isomaltotriose, and linear DP<sub>4</sub> when 50W-X4 resin is used. List DP<sub>4+</sub> KF as default KF for DP<sub>5+</sub> calcn when 50W-X4 resin is used.

### 31.234

#### Preparation of Sample

Det. approx dry substance as in 31.214. Dil. sample by wt to ca 12% dry substance with H<sub>2</sub>O. Add ca 0.3 g mixed exchange resin to ca 6 g dild sample and shake 10 min to remove possible interfering ionic material which elutes in DP<sub>4+</sub> region.

### 31.235

#### Determination

Rinse syringe with dild sample 4 times before injection. Inject 30  $\mu$ L dild sample, 31.234. Best accuracy is obtained when dry substance solids injected for sample and std are equiv. Integrate eluted peaks, using System I and Method I. After injection, wash syringe 4 times with warm tap H<sub>2</sub>O, allowing air bubbles to scrub syringe walls. Wash syringe twice with H<sub>2</sub>O.

### 31.236

#### Calculations

Results are computed automatically when using 31.229(c). List fructose, glucose, maltulose, and other DP<sub>2</sub> results. Combine maltotriose, panose-isomaltotriose, and linear DP<sub>4</sub> results, and list sum as DP<sub>3-4</sub>. Sum remaining results and list as DP<sub>5+</sub>. Report results on ash-free, carbohydrate dry substance basis. In absence of computing integrator, list areas for fructose (*f*), glucose (*g*), maltulose, other DP<sub>2</sub>, sum of maltotriose, panose-isomaltotriose

and linear DP<sub>4</sub>, and sum of DP<sub>5+</sub>, and compute result by equation:

$$\% \text{ Component} = \frac{[(\text{Area component})(\text{KF component})] \times 100}{\{[(\text{Area}_1)(\text{KF}_1)] + [(\text{Area}_2)(\text{KF}_2)] + \dots + [(\text{Area}_{5+})(\text{KF}_{5+})]\}}$$

## 32. Vegetable Products, Processed

### CANNED PRODUCTS

#### Drained Weight—Procedure

##### 32.001

##### Sieves

See *Definition of Terms and Explanatory Notes*, item (16). Use 8" (20 cm) diam. for containers  $\leq 3$  lb (1.36 kg) or 12" (30 cm) diam. for containers  $> 3$  lb.

##### 32.002

##### Determination

Weigh full can, open, and pour entire contents on No. 8 sieve (use  $7/16$ " sieve for canned tomatoes). Without shifting product, incline sieve at ca 17–20° angle to facilitate drainage. Drain 2 min, directly weigh either drained solids or free liq., and weigh dry empty can. From wts obtained, det. % liq. and % drained solid contents.

#### 32.003 Preparation of Sample—Procedure

(a) *Products composed of solid and liquid portions.*—See 22.008(d). If only solid portion is required for analysis or examination, thoroly grind drained vegetables in mortar or food chopper. If composite of solid and liq. portion is required, thoroly grind entire contents of can in mortar or food chopper. In all cases, thoroly mix portion used and store balance in g-s container. Unless analysis is to be completed in reasonably short time, det. H<sub>2</sub>O in portion of sample prepd as above. To prevent decomposition, dry remainder, grind, mix thoroly, and store in g-s container. (Second H<sub>2</sub>O detn is required in this method.)

(b) *Comminuted products (tomato juice, tomato catsup, strained vegetables).*—Thoroly shake unopened container to incorporate any sediment. Transfer entire contents to large glass or porcelain dish, and mix thoroly, continuing stirring  $\geq 1$  min. Transfer well mixed sample to g-s container and shake or stir thoroly each time before removing portions for analysis.

#### Water Activity (7)—Official First Action

##### 32.004

##### Principle

Water activity,  $a_w$ , is ratio of vapor pressure of H<sub>2</sub>O in product to vapor pressure of pure H<sub>2</sub>O at same temp. It is numerically equal to 1/100 of relative humidity (RH) generated by product in closed system. RH can be calcd from direct measurement of partial vapor pressure or dew point or measured indirectly by sensors whose physical or elec. characteristics are altered by RH to which they are exposed. Instruments are checked or calibrated on basis of RH generated by std salt slushes.

##### 32.005

##### Instruments and Systems

(Select 1 of following instruments or systems to perform test. Each has different application limitations because of interferences from other volatile components of products being measured. Check with instrument manufacturer for more specific limitations.)

(a) *Change in electrical conductivity of immobilized salt soln.*—Instrument available from American Instrument Co.; Beckman Instruments, Inc., 89 Commerce Rd, Cedar Grove, NJ 07009; Nova Sina AG, Andreastrasse 7-11, CH 8050, Zurich, Switzerland; or Rotronic AG, CH 8047, Zurich, Switzerland. Immobilized salt sensors are affected by polyols such as glycerol and glycol and by volatile amines.

(b) *Change in electrical capacitance of polymer thin films.*—Instrument available from WeatherMeasure, 3213 Orange Grove, N Highlands, CA 95660 or General Eastern Corp., 36 Maple St, Watertown, MA 02172. Note: Polymer thin film sensors are affected by HOAc.

(c) *Dew point by chilled mirror technic.*—Instrument available from EG&G, Inc., Environmental Equipment Div., 151 Bear Hill Rd, Waltham, MA 02154 or General Eastern Corp. Dew point measurements can be affected by condensables with lower critical temp. than H<sub>2</sub>O.

(d) *Longitudinal change in dimensions of water-sorbing fiber.*—Instrument available from Abbeon Cal, Inc., 123 Gray Ave, Santa Barbara, CA 93101 or G Lufft Metallbarometerfabrik, D-7, Postfach 692, Neue Weinsteige 22, Stuttgart, West Germany.

(e) *Partial water vapor pressure by manometric system.*—Partial H<sub>2</sub>O vapor pressure measurements can be made useless by living products that respire, such as grains or nuts; by active fermentation; or by products that expand excessively when subjected to high vac.

(f) *Relative weight of moisture sorbed by anhydrous hydrophilic solid, e.g., microcrystalline cellulose.*—See J. Agr. Food Chem. 22, 326(1974).

##### 32.006

##### Apparatus and Reagents

(As needed for instrument or system selected)

(a) *Dew point instrument.*—Equipped to measure temp. to  $\pm 0.1^\circ$ . See 32.005(c).

(b) *Forced-draft cabinet.*—Const temp., set to maintain  $25 \pm 1^\circ$ ; capacity  $\geq 0.06$  m<sup>3</sup> (2 cu ft); with access port to accommodate instrument sensor leads. Use in conjunction with (c).

(c) *Insulated box with cover.*—Large enough to hold test container, (e), and small enough to fit in forced-draft cabinet, (b); with access port to accommodate instrument sensor leads. Protect test container from short-term temp. fluctuations.

(d) *Manometric system.*—Sensitive to pressure differential of  $\pm 0.01$  mm Hg (1.33 Pa). See 32.005(e).

(e) *Test containers.*—120 or 240 mL (4 or 8 oz) wide-mouth or Mason glass jars with Al- or Teflon-lined screw caps and gaskets. Check integrity of cap seals and sensor leads by any means available, e.g., ability of system to hold vac., using Tesla coil.

(f) *Water bath.*—Capable of maintaining temp. const within  $0.1^\circ$  at  $25 \pm 1^\circ$ ; capacity sufficient to hold measuring chamber of selected app.

(g) *Hydrophilic solid.*—Microcryst. cellulose, Type PH-101 (FMC Corp., 2000 Market St, Philadelphia, PA 19103, or equiv.).

(h) *Reference salts.*—ACS reagent grade, fine crystal. See Table 32.01.

Table 32.01 Water Activity of Reference Salt Slushes at 25°

Salt	$a_w$	Salt	$a_w$
MgCl <sub>2</sub>	0.328	KBr	0.809
K <sub>2</sub> CO <sub>3</sub>	0.432	(NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub>	0.810
Mg(NO <sub>3</sub> ) <sub>2</sub>	0.529	KCl	0.843
NaBr	0.576	Sr(NO <sub>3</sub> ) <sub>2</sub>	0.851
CoCl <sub>2</sub>	0.649	BaCl <sub>2</sub>	0.902
SrCl <sub>2</sub>	0.709	KNO <sub>3</sub>	0.936
NaNO <sub>3</sub>	0.743	K <sub>2</sub> SO <sub>4</sub>	0.973
NaCl	0.753		

**32.007****Preparation of Reference Salt Slushes**

Place selected ref. salt in test container to depth of ca 4 cm for more sol. salts (lower  $a_w$ ), to depth of ca 1.5 cm for less sol. salts (higher  $a_w$ ), and to intermediate depth for intermediate salts. Add  $H_2O$  in ca 2 mL increments, stirring well with spatula after each addn, until salt can absorb no more  $H_2O$  as evidenced by free liq. Keep free liq. to min. needed to establish satn of salt with  $H_2O$ . Slushes are ready for use upon completion of mixing, and are usable indefinitely (except for some high  $a_w$  salts susceptible to bacterial attack), if contained in manner to prevent substantial evapn losses. Some slushes, e.g., NaBr, may solidify gradually by crystal coalescence, with no effect on  $a_w$ .

**32.008****Calibration**

Select  $\geq 5$  salts to cover  $a_w$  range of interest or range of sensor being used. Measure humidity generated by each salt slush in terms of instrument readout, as in **32.009**. Plot readout against  $a_w$  values given in Table **32:01** for selected salts, using cross-section paper scaled for reading to 0.001  $a_w$  unit. Draw best av. smooth line thru plotted points. Use this calibration line to translate sensor instrument readout of samples to  $a_w$ , or to check vapor pressure or dew point instruments for proper functioning.

**32.009****Determination**

Place calibration slush or sample in forced-draft cabinet, (b), or  $H_2O$  bath, (f), until temp. is stabilized at  $25 \pm 1^\circ$ . Transfer salt slush or sample to test container, (e), seal container with sensing device attached, and place in temp. control device. Use vol. of sample or slush  $> 1/20$  total vol. sample container plus any associated void vol. of sensing system, but not so much as to interfere with operation of system. Record instrument response at 15, 30, 60, and 120 min after test container is placed in temp. control device, or record response on strip chart. Two consecutive readings, at indicated intervals, which vary by  $< 0.01 a_w$  unit are evidence of adequately close approach to equilibrium. Continue readings at 60-min intervals, if necessary. Convert last reading to  $a_w$  by calcn from physical measurements or by ref. to calibration line. Make all measurements within range of calibration points; do not extrapolate calibration line. Make all measurements in same direction of change, and, if required by properties of sensor, expose sensor to controlled RH below ambient before starting each measurement.

**32.010 Total Solids (2)—Official Final Action**

To flat-bottom metal dish with tight-fitting cover, add ca 15 mg diat. earth filter-aid/sq cm, dry ca 30 min at  $110^\circ$ , cool in desiccator, weigh, and to each dish add sample of such size that dry residue will be  $\geq 9$  but  $\leq 30$  mg/sq cm. Weigh as rapidly as possible to avoid moisture loss. Mix with filter-aid and distribute uniformly over bottom of dish, dilg with  $H_2O$  if necessary to facilitate distribution. Bring sample to apparent dryness (remaining moisture not more than ca 50% dry solids) by one of following methods:

(1) Place sample on boiling  $H_2O$  bath and remove when samples reach apparent dryness.

(2) Place sample in forced-draft oven at  $70^\circ$ . Oven must have rapid air circulation and enough interchange of outside air to remove moisture rapidly. Examine dishes at intervals of  $\leq 30$  min, and remove as soon as they reach apparent dryness.

(3) Place sample in vac. oven at  $70^\circ$  with release cock left partly open to allow rapid flow of air thru oven at  $\geq 310$  mm Hg (41.3 kPa) pressure. Examine dishes at 30 min intervals and remove any that reach apparent dryness.

Place partially dried samples in vac. oven with bottoms of dishes in direct contact with shelf. Measure temp. of oven by thermometer in direct contact with shelf. Oven must be so constructed that temp. variations from one part of shelf to another does not exceed ca  $2^\circ$ . Admit dry air to oven at rate of 2–4 bubbles/sec by bubbling through  $H_2SO_4$ . Dry samples 2 hr at  $69\text{--}71^\circ$  (oven may be as low as  $65^\circ$  at start of drying, but must reach  $69\text{--}71^\circ$  before end of first hr) at pressure  $\leq 50$  mm Hg (6.6 kPa). As dried sample will absorb appreciable amt of moisture on standing over most desiccating agents, cover quickly, and weigh as soon as possible after sample reaches room temp.

**32.011 Insoluble Solids (3)—Official Final Action**

Wash 20 g sample repeatedly with hot  $H_2O$ , centrfg after each addn of  $H_2O$  and pouring clear supernate thru weighed filter paper on buchner. (Filter used is 1 of 2 such papers dried 2 hr at  $100^\circ$  and weighed in covered dish. Use second paper, if necessary, when first becomes clogged.) After 4 or 5 washings, transfer remaining insol. matter to filter, dry in uncovered dish 2 hr at  $100^\circ$ , cover, cool in desiccator, and weigh.

**32.012 Alcohol-Insoluble Solids in Canned Peas (4) Official Final Action**

Pour sample on No. 8 screen, using 8" (20 cm) size for container of  $< 3$  lb net wt and 12" (30 cm) for larger amts. Spread peas evenly and let drain. Transfer peas to white pan and remove any foreign material. Add vol.  $H_2O$  equal to double vol. original sample.

Pour peas back on screen, spreading evenly, tilt screen as much as possible without shifting peas, and drain 2 min. With cloth, wipe surplus moisture from lower surface of screen. Grind drained peas in high-speed blender or food chopper until cotyledons are reduced to smooth paste, stir, and weigh 20 g ground material into 600 mL beaker. Add 300 mL 80% alcohol, stir, cover beaker, and bring to bp. Simmer slowly 30 min.

Fit buchner with filter paper of appropriate size (previously prep'd by drying in flat-bottom dish 2 hr at  $100^\circ$ , covering with tight-fit cover, cooling in desiccator, and weighing at once). Apply suction and transfer contents of beaker to buchner so as to avoid running over edge of paper. Suck dry and wash material on filter with 80% alcohol until washings are clear and colorless.

Transfer paper and alcohol-insol. solids to dish used in prep'n of paper, dry uncovered 2 hr at  $100^\circ$ , place cover on dish, cool in desiccator, and weigh at once. From this wt deduct wt dish, cover, and paper. Calc. % by wt of alcohol-insol. solids.

**32.013 Soluble Solids—Official Final Action**

% Total solids, **32.010** – % insol. solids, **32.011** = % sol. solids.

**Soluble Solids in Tomato Products (5) Official Final Action****32.014****Apparatus and Reagents**

(a) *Filters*.—Cut stems off 75 mm id glass or plastic funnels ca 1 cm from apex at  $90^\circ$  angle and firepolish ends. Set funnels in 150 mL jars, ca 55 mm id. If 150 mL beakers are used, close pouring spout with tape to prevent evapn. Insert folded paper, Whatman No. 2V, 12.5 cm, or equiv., in funnel.

(b) *Refractometer*.—Sensitive to 0.0001  $n$ .

(c) *Ultracentrifuge*.—Centrf. should produce force of ca  $150,000 \times g$  (lesser force may be satisfactory for some samples). International No. B-60 or B-20A (Damon/IEC Div., 300 Second Ave, Needham Hts, MA 02194) are satisfactory.

(d) *Pectic enzyme*.—(1) *Dry preparation*.—In diat. earth base, e.g., Pectinol R-10 (Rohm and Haas Co.), Klerzyme® analytical (G.B. Fermentation Industries), or Spark-L® (Miles Laboratories, Inc). (2) *Soln.*—Prep. 0.4–1% aq. soln of (1); mix thoroly and let settle. Use clear supernate. Liq. preps are also available commercially; dil., if necessary, before use.

**32.015****Preparation of Sample**

(a) *Filtration without dilution*.—Weigh 100 g sample at room temp. and add weighed amt (0.2–1.0 g) dry enzyme prep. Immediately mix with spoon or spatula to avoid evapn and transfer to filter. Tamp so sample is in close contact with paper and cover with petri dish (top or bottom portion) to form loose seal with top of funnel. Discard samples that do not filter in reasonable length of time (<1 hr). Mix 0.2–1.0 g dry enzyme prep. with 100 g fresh sample, seal in closed container, and incubate 30–60 min at ca 40°. Cool nearly to room temp. before opening container, remix sample, and transfer to filter. For samples that still do not filter within 1 hr, proceed as in (b).

(b) *Filtration with dilution*.—(Applicable to samples contg ≥35% solids that will not filter when treated as in (a).) Add 100 g enzyme soln to 100 g sample and immediately mix with spoon or spatula to avoid evapn. (Mech. mixer (e.g., Osterizer) with sealed blending container may be used.) Alternately blend and shake to dislodge and break up lumps sticking to container. Examine mixt. carefully for lumps and continue mixing until homogeneous. Transfer to filter and cover with petri dish.

(c) *Centrifugation*.—(Applicable to all samples.) Centrf. sample in ultracentrf. until reasonably clear serum is obtained (serum of some samples may be slightly turbid and/or red from presence of finely divided particles of pigment). Add dry enzyme as in (a) to decrease centrfg time. Protect sample from evapn during centrfg and before reading in refractometer.

**32.016****Determination**

(a) *With filtration*.—Adjust refractometer for refractive index ( $n$ ) of 1.3330 with H<sub>2</sub>O at 20°. Let sample filter into jar or beaker until filtrate is clear (some color and turbidity may be tolerated). Quickly remove funnel and transfer large drop of filtrate directly from funnel to refractometer prism. (Tip of funnel may touch refractometer prism but should not scratch prism.) Replace funnel in jar. Read refractometer, preferably at 20°, but if humidity causes condensation of moisture on prism, make measurements at room temp. and correct readings to std temp. as in 52.016. Read  $n$  or % sucrose on refractometer. If  $n$  is read, convert to % sucrose from 52.012.

Let sample filter several min more. Repeat reading by removing funnel and transferring drop of filtrate to refractometer prism. The 2 readings should agree within 0.0002 $n$  or 0.1% sucrose. If not, repeat readings on successive portions of filtrate until agreement is obtained. Erratic readings indicate evapn of sample or faulty mixing and/or filtration technic.

Read clear supernate of 1% soln of dry enzyme on refractometer and convert to % sucrose. Subtract  $1.15 \times B \times C$  from direct reading on sample (as % sucrose); where 1.15 = correction for insol. solids in weighed sample, assuming 12.5% total solids to be insol. solids;  $B$  = % enzyme prep. added to sample; and  $C$  = reading as sucrose obtained on 1% soln.

If dild sample is used, subtract  $0.55 \times D \times C$  from reading on sample (as % sucrose); 0.55 = correction for insol. solids, as above, and  $D$  = % enzyme prep. added to dild H<sub>2</sub>O. Multiply corrected reading for dild sample by 2 and add addnl correction according to following table:

Natural Tomato Sol. Solids as % Sucrose Corrected for Enzyme $\times 2$	Correction
25.0	0.3
30.0	0.4
35.0	0.5
40.0	0.7
45.0	0.8
50.0	0.9

(b) *With centrifugation*.—Remove serum from rotor or centrf. tube with pipet or medicine dropper, and transfer to refractometer prism; avoid including solid particles as much as possible. If sharp line is not obtained on refractometer because of suspended solids, increase centrfg time or speed, or add enzyme to sample before centrfg. Calc. sol. solids as above.

(c) *Correction for added salt*.—(Use only when sample contains added salt and  $R > S$ .) Correct refractometer reading expressed as % sucrose at 20° for added salt by following formula:  $S = (R - N) \times 1.016$  = total sol. solids as sucrose exclusive of added salt; where  $S$  = refractometer reading as sucrose corrected for added NaCl,  $R$  = total sol. solids as sucrose, and  $N$  = % total chlorides expressed as NaCl (detd by 32.023).

**32.017 Specific Gravity (6)—Official Final Action**

(Applicable to comminuted tomato products)

Det. sp gr at 20/20°, using Gay-Lussac or similar small-neck bottle without cap. Clean and calibrate bottle at 20° as in 9.010, strike off excess H<sub>2</sub>O with straight edge, wipe bottle dry, and weigh immediately. Cool sample to 16–18°, fill bottle with the pulp, and centrf. 1 min at ca 1000 rpm. Add enough pulp to fill bottle to top and centrf. again. Remove bottle and take temp. of pulp, inserting thermometer so that no air is introduced. When temp. is just 20°, remove thermometer, add enough pulp at same temp. to have bottle slightly over full, and strike off even with straight edge. Clean outside of bottle and weigh at once to nearest 0.01 g.

Sp gr = wt pulp in bottle/wt H<sub>2</sub>O at 20° that bottle holds.

**32.018 Ash—Official Final Action**

See 31.012 or 31.013.

**32.019 Alkalinity of Ash—Official Final Action**

Proceed as in 22.027. Express result as mL 1N acid required to neutze ash from 100 g sample.

**Calcium (7)—Official Final Action**

(Applicable to canned lima beans, potatoes, and tomatoes)

**32.020****Reagents and Apparatus**

See 36.050 and 36.051.

**32.021****Preparation of Sample**

Thoroly comminute entire contents of can (representative portion if larger than No. 303 size can) in high-speed blender. Weigh 50 g sample (100 g in absence of declaration of added Ca) into Pt or porcelain dish. Evap. to dryness, using forced-draft oven, IR radiation, or other convenient means. Ash and treat as in 36.052.

**32.022****Determination**

Transfer 100 mL aliquot prepd sample soln to 250 mL beaker and adjust to pH 3.5 with 10% KOH soln added dropwise, using pH meter and mag. stirrer. Pass sample soln thru resin column

(column is in chloride form), collecting effluent in 400 mL beaker at flow rate of 2–3 mL/min. Wash column with two 50 mL portions H<sub>2</sub>O, passing first portion thru at same rate as sample soln and second at 6–7 mL/min. Finally pass enough H<sub>2</sub>O freely thru column to make 250–300 mL final vol. Adjust to pH 12.5–13.0, using pH meter and mag. stirrer, with KOH–KCN soln, **1.022(b)**. Add 0.100 g ascorbic acid and 200–300 mg hydroxynaphthol blue indicator. Titr. immediately with 0.01M EDTA soln thru pink to deep blue end point, using mag. stirrer.

$$\% \text{ Ca} = \text{mL EDTA} \times (\text{molarity EDTA soln}/0.01) \times 0.4008 \times 2 \times 100/\text{mg sample.}$$

#### Sodium Chloride—Official Final Action

##### 32.023 Method I

Proceed as in **3.072** or **3.074**, using HNO<sub>3</sub> soln of ash, **3.071**. Calc. and report results as % NaCl.

##### 32.024 Method II (Rapid Method) (8)

Weigh ca 5 g material, transfer with 80% alcohol to 100 mL vol. flask, and add enough 80% alcohol to give vol. of ca 50 mL. Shake well to suspend all insol. material. Add 1 mL HNO<sub>3</sub> and with pipet add excess of 0.1N AgNO<sub>3</sub> soln. Dil. to 100 mL with alcohol. Transfer mixt. to centr. bottle and centr. 5 min at ca 1800 rpm. Pipet 50 mL supernate into 300 mL erlenmeyer, add 2 mL satd FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>2</sub> soln and 2 mL HNO<sub>3</sub>, and titr. to permanent light brown with 0.1N NH<sub>4</sub>SCN.

$$\% \text{ NaCl} = [(\text{mL } 0.1N \text{ AgNO}_3/2) - \text{mL } 0.1N \text{ NH}_4\text{SCN}] \times 0.5844 \times 100/50 \times W,$$

where *W* = g sample.

#### Method III (Potentiometric Method) (9)

##### 32.025

##### Principle

Product is dispersed with H<sub>2</sub>O and acidified; sol. chlorides are titrd potentiometrically with AgNO<sub>3</sub>. Applicable to levels ≥0.03% NaCl. For convenience in calcs, wts or vols and normality are specified so that 1 mL AgNO<sub>3</sub> = 0.1% NaCl. If balance permitting rapid weighing of specified wt is not available, convenient wt sample and normality AgNO<sub>3</sub> soln may be used.

##### 32.026

##### Apparatus

(a) *Balance*.—Capacity, ≥200 g, taring range, ≥100 g, readability, ≤0.01 g. Mettler No. P1200 (superseded by P1210) (Mettler Instrument Corp., PO Box 100, Princeton, NJ 08540), or equiv., is convenient.

(b) *Electrodes*.—Ag billet combination electrode (Beckman No. 39261, or equiv.), or sep. indicating Ag (Beckman 39604, Orion 94-17, Fisher 13-639-122, or equiv.), and glass ref. (Beckman 40455, Orion 90-02, Fisher 9-313-216, or equiv.) electrodes. Before initial use and before each day's use, if necessary, clean Ag billet electrode tip with scouring powder or other suitable material and rinse thoroly with H<sub>2</sub>O. (Hot H<sub>2</sub>O may be required with some kinds of samples.) Clean other electrodes as recommended by manufacturer. Reclean as frequently as necessary to prevent drifting of end point reading. With some samples, periodically rinse electrodes with H<sub>2</sub>O and wipe with tissue to prevent accumulation of film. It is unnecessary to coat Ag billet electrodes with AgCl.

(c) *Magnetic stirrer*.—Operating thru variable transformer to permit range of speed which, once set, is const.

(d) *pH meter*.—Preferably direct reading, with scale divisions 10 mv or less; range at least ±700 mv, e.g., digital type.

##### 32.027

##### Reagents

(a) *Nitric acid, dilute*.—(1+49). Dil. 20 mL HNO<sub>3</sub> to 1 L with H<sub>2</sub>O.

(b) *Silver nitrate std soln*.—0.0856N. Dissolve 14.541 g AgNO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L in vol. flask. Stdze as in **32.028**, and adjust to exact normality specified so that with indicated sample wt, 1 mL = 0.1% NaCl. Store in Pyrex container out of direct sunlight. Soln is stable in room light.

(c) *Sodium chloride std soln*.—0.0856N. Dissolve in H<sub>2</sub>O 5.000 g NaCl (if assay is <100.0% NaCl, divide 5.000 g by % NaCl/100 to obtain corrected wt), previously dried 2 hr at 110°, and dil. to 1 L in vol. flask.

(d) *Water*.—Distd or deionized, halogen-free by following test: Add 1 mL ca 0.1N AgNO<sub>3</sub> and 5 mL HNO<sub>3</sub> (1+4) to 100 mL of the H<sub>2</sub>O. No more than slight turbidity should be produced.

##### 32.028

##### Standardization

Pipet 25 mL NaCl std soln into 250 mL beaker, dil. to ca 50 mL with H<sub>2</sub>O, and add 50 mL HNO<sub>3</sub> (1+49). Insert electrodes, start mag. stirrer, and stir throughout titrn at const rate producing vigorous agitation without splashing. Titr. with AgNO<sub>3</sub> std soln, adjusting increments with rate of voltage change so that accurate plot of mv against mL AgNO<sub>3</sub> soln can be prepd. Add total of 50 mL AgNO<sub>3</sub> soln to obtain complete curve.

Det. inflection point by drawing 2 straight lines with 45° slope with respect to axes and tangent to titrn curve at the 2 points of greatest curvature. Inflection point is at intersection of titrn curve with line drawn parallel to, and midway between, other 2 lines. From vol. AgNO<sub>3</sub> soln used, calc. normality and adjust to 0.0856N. Restdze occasionally. Use inflection point as end point in titrg samples. Recheck end point potential occasionally, and redet. when either individual electrode, combination electrode, or pH meter is replaced by prepg new titrn curve.

For greatest accuracy, when series of detns on same food is performed, det. and use end point from titrn curve of that food rather than using end point obtained with NaCl std soln.

##### 32.029

##### Preparation of Sample

(a) *Clear liquids with low viscosity*.—(Fruit juices, clear soups, wines, etc.) Use directly.

(b) *Comminuted products*.—(Tomato juice, tomato catsup, strained vegetables, etc.) Thoroly shake unopened container to incorporate any sediment. Transfer entire contents to large glass or porcelain dish and mix thoroly, continuing stirring ≥1 min. Transfer to g-s container, and shake or stir thoroly each time before removing portions for analysis.

(c) *General method for heterogeneous (fish, meat, etc.), low moisture (cereal products, etc.), and hard-to-disperse, homogeneous (cheese, peanut butter, etc.) foods*.—Weigh 50.0 g sample into 1 L (qt) container of high-speed blender and add 450 g H<sub>2</sub>O. Cover, start blender at low speed by use of variable transformer for initial dispersion, and blend thoroly at high speed (1–2 min is usually adequate). Equiv. of 5 g sample is conveniently dispensed thru 50 mL pipet with tip cut off. Thoroly mix sample suspension immediately before pipetting aliquot for analysis so that solid material is uniformly suspended.

(d) *Other types of foods*.—Prep. sample by method (a), (b), (c), or other suitable method.

To preserve samples or sample suspensions for future analysis, add 0.5 mL ca 37% HCHO soln/100 g sample or sample suspension, mix well, and store at room temp. Correct for diln by HCHO soln by multiplying % NaCl by 1.005.

**32.030****Determination**

(a) *For products containing less than 5 per cent salt.*—Place 5.00 g (or 5.00 mL if concn is to be expressed on w/v basis) prepd sample from (a) or (b) or 50.0 g from (c) into tared 250 mL beaker; add H<sub>2</sub>O to ca 50 mL if (a) or (b) is used. (Use boiling H<sub>2</sub>O with samples such as butter to melt fat.) Add 50 mL HNO<sub>3</sub> (1+49). Titr. as in 32.028, using 10 mL buret if salt content is ≤1%.

$$\% \text{ NaCl} = \text{mL } 0.0856N \text{ AgNO}_3 / 10.$$

(b) *For products containing 5 or more per cent salt.*—Place 5.00 g (or 5.00 mL if concn is to be expressed on w/v basis) prepd sample from (a) or (b) into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Mix, and transfer aliquot contg 50–250 mg NaCl to 250 mL beaker. If sample is prepd by (c), transfer weighed aliquot contg 50–250 mg NaCl to tared 250 mL beaker. Proceed as in 32.028, beginning “. . . dil. to ca 50 mL with H<sub>2</sub>O. . . .”

$$\% \text{ NaCl} = F \times \text{mL } 0.0856N \text{ AgNO}_3 / 10,$$

where  $F = \text{diln factor} = 100/\text{mL aliquot titrd if sample is prepd by (a) or (b) or } 50/\text{g aliquot titrd if prepd by (c)}.$

(c) *General case.*—Accurately weigh approx. sample wt stated. (If % NaCl ≥5%, weigh <5 g sample rather than dilg to 100 mL, if more convenient.) Use ca 0.1N AgNO<sub>3</sub> soln, accurately stdzd as in 32.028, without adjusting to specific normality, and titr. as in 32.028.

$$\% \text{ NaCl} = \text{mL AgNO}_3 \times N \text{ AgNO}_3 \times 0.05844 \times 100/\text{g sample}.$$

If sample is overtitr, add NaCl std soln, and complete titrn. Correct for vol. of std soln added.

**32.031 Reducing Sugars Before Inversion****Official Final Action**

Weigh 20 g sample into 200 mL vol. flask, dil. with ca 100 mL H<sub>2</sub>O, clarify with slight excess of neut. Pb(OAc)<sub>2</sub> soln, 31.021(d), dil. to vol., and filter. Remove excess Pb with anhyd. Na<sub>2</sub>SO<sub>4</sub> or with dry Na or K oxalate. Filter, and det. reducing sugars as in 31.038. Express result as % invert sugar.

**32.032 Reducing Sugars After Inversion****Official Final Action**

Transfer 50 mL filtrate, 32.031, to 100 mL vol. flask, add 5 mL HCl, and let stand overnight, as in 31.026(c). Nearly neutze with NaOH soln, cool, dil. to vol., and det. reducing sugars in aliquot as in 31.038. Express result as % invert sugar.

**32.033 Sucrose—Official Final Action**

See 31.031.

**32.034 Total Acids—Official Final Action**

Proceed as in 22.060 or 22.061, using 5 g sample. Express result as mL 1N alkali required to neutze 100 g sample.

**Oxalic Acid (10)—Official Final Action****32.035****Reagents**

(a) *Indicator paper.*—Short-range Alkacid (No. 2, pH 3.5–5.5, Fisher Scientific Co., or equiv.).

(b) *Potassium permanganate solns.*—(1) *Approx. 0.1N.*—Prep. and stdze as in 50.025–50.026. (2) *Approx. 0.01N.*—Dil. 100 mL 0.1N to 1 L. Prep. fresh before use.

(c) *Acetate buffer soln.*—pH 4.5. Dissolve 2.5 g anhyd. CaCl<sub>2</sub> in 50 mL HOAc (1+1) and add to soln of 33 g NaOAc·3H<sub>2</sub>O dild to 50 mL.

(d) *Wash liquid.*—Dil. 12.5 mL HOAc to 250 mL with H<sub>2</sub>O. Add powd Ca oxalate, shake, and let stand. Repeat addn and shaking

to satn. Cool to 4° and store in refrigerator. Just before use, filter amt needed. Keep cold during filtration and use.

(e) *Tungstophosphoric acid reagent.*—Dissolve 2.5 g Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O in mixt. of 4 mL H<sub>3</sub>PO<sub>4</sub> and 50 mL H<sub>2</sub>O, and dil. to 100 mL with H<sub>2</sub>O.

(f) *Lanthanum soln.*—5%. Wet 5.9 g La<sub>2</sub>O<sub>3</sub> with H<sub>2</sub>O, very slowly add 25 mL HCl to dissolve, and dil. to 100 mL with H<sub>2</sub>O.

(g) *Calcium std solns.*—(1) *1 mg/mL.* Slurry 2.497 g CaCO<sub>3</sub> (primary std grade) in 1 L vol. flask with 300 mL H<sub>2</sub>O. Carefully add 10 mL HCl. After CO<sub>2</sub> is completely released, dil. to vol. with H<sub>2</sub>O. (2) *0.05 mg/mL.*—Dil. 5.0 mL soln (1) to 100 mL with H<sub>2</sub>O.

**32.036****Apparatus**

*Atomic absorption spectrophotometer.*—Perkin-Elmer Model 303, or equiv. double beam instrument. Typical operating parameters for this app. are given in Table 32:02. Operator must be familiar with optimum settings for app. and use table only as guide. (Caution: See 51.006.)

**32.037****Preparation of Sample**

Det. net wt of contents of can. Transfer quant. to high-speed blender, rinsing can with 100 mL H<sub>2</sub>O added from buret or pipet. Homogenize 15 min and cool to room temp.

Accurately weigh ca 35 g slurry into 800 mL beaker. Add H<sub>2</sub>O to bring total wt to ca 300 g; then add 55 mL 6N HCl. Add 2 drops *caprylic alcohol*, and boil 15 min. Cool, transfer quant. to 500 mL vol. flask, dil. to vol. with H<sub>2</sub>O, mix, and let stand overnight. Mix, and filter thru fast quant. paper, discarding first 100 mL filtrate.

**32.038****Precipitation of Oxalic Acid**

Pipet 25 mL filtrate into 50 mL erlenmeyer, add 5.0 mL tungstophosphoric acid reagent, mix, and let stand ≥5 hr. Filter thru Whatman No. 30 quant. paper, or equiv. Pipet 20 mL filtrate into 50 mL conical centr. tube and add NH<sub>4</sub>OH dropwise to pH 4–4.5, using indicator paper, (a). Add 5 mL buffer soln, (c), and stir with glass rod. Rinse rod into centr. tube with small stream of H<sub>2</sub>O and let stand overnight.

Centrf. ≥15 min at 1700 rpm to compact ppt. Decant supernate with one smooth continuous inversion of centr. tube. Hold tube upside down and let remaining supernate drip completely onto clean filter paper. Do not disturb Ca oxalate ppt. Wash ppt by completely breaking it into fine suspension with fine jet stream of 20 mL filtered cold wash liq., (d). Repeat centrfg and decanting steps, taking care that ppt is drained completely. Discard paper. Add 5 mL H<sub>2</sub>SO<sub>4</sub> (1+9) to ppt. Proceed with permanganate titrn or AA detn.

**32.039****Determination by Permanganate Titration**

Heat sample and blank (5 mL H<sub>2</sub>SO<sub>4</sub> (1+9) in 50 mL centr. tube) prepd solns in boiling H<sub>2</sub>O bath. Titr. *hot* soln with 0.01N KMnO<sub>4</sub> until first pink persists ≥30 sec.

$$\text{mg Oxalic acid}/100 \text{ g product} =$$

$$\text{mL } 0.01N \text{ KMnO}_4 \times 1350 \times (\text{net wt} + 100 \text{ g}) / (\text{wt slurry taken} \times \text{net wt})$$

where 1350 = 0.45 (mg anhyd. oxalic acid equiv. to 1 mL 0.01N KMnO<sub>4</sub>) × [(30/20) × (500/25) (diln factors)] × 100 (to convert to 100 g product).

**32.040****Determination by Atomic Absorption**

Quant. transfer entire contents of centr. tube to 10 mL vol. flask with H<sub>2</sub>SO<sub>4</sub> (1+9) and dil. to vol. with same soln (*soln I*). Pipet 2 mL *soln I* into 50 mL vol. flask contg 10.0 mL La soln,

(f). Dil. to vol. with H<sub>2</sub>O (*soln II*). Transfer 15.0 mL *soln II* to 25 mL vol. flask contg 2 mL La soln. Dil. to vol. with H<sub>2</sub>O.

Pipet 0, 2.0, 4.0, 6.0, 8.0, 10.0, and 12.0 mL CaCO<sub>3</sub> soln, (g)(2), into sep. 50 mL vol. flasks. Pipet 10 mL La soln into each and dil. to vol. with H<sub>2</sub>O.

Set instrument to previously established optimum conditions or according to manufacturer's instructions. Det. *A* of sample and std solns, taking  $\geq 2$  std readings before and after sample readings. Flush burner with H<sub>2</sub>O and check 0 point between readings. Correct for reagent blank reading, if significant, and det. Ca concn from std curve obtained by plotting *A* against  $\mu\text{g Ca/mL}$ .

$$\text{mg Oxalic acid/100 g product} = \frac{(\mu\text{g Ca/mL}) \times 2807.5 \times (\text{net wt} + 100 \text{ g})}{(\text{wt slurry taken} \times \text{net wt})},$$

where 2807.5 = 2.246/1000 (to convert  $\mu\text{g Ca}$  to mg oxalic acid)  $\times [25 \times (50/15) \times (10/2) \times (30/20) \times (500/25)$  (diln factors)]  $\times 100$  (to convert to 100 g product).

**Table 32.02 Operating Parameters for Oxalic Acid Determination**

Wavelength, nm	422.7
Slit width, mm	1-setting 4
Hollow Zn-Ca cathode lamp, ma	15–20
Air, aspirating	9.0 (scale divisions)
Acetylene fuel	9.5 (scale divisions)
Flame	reducing

Sample uptake, mL/min	5
Optimum concn range, $\mu\text{g/mL}$	0–10

#### Lactic Acid—Official Final Action

##### 32.041

##### Preparation of Solution

Weigh 50 g ground and mixed sample into tared centrf. bottle and add 100 mL H<sub>2</sub>O. Make acid to Congo red paper with 1*N* H<sub>2</sub>SO<sub>4</sub>. Adjust wt of contents of bottle to 200 g by addn of H<sub>2</sub>O, shake vigorously, and centrf. Decant supernate and weigh 100 g into 100–110 mL vol. flask. Dil. to 110 mL mark with H<sub>2</sub>O, shake, and pipet 50 mL into continuous extractor (Fig. 16.01). Add 0.5 mL H<sub>2</sub>SO<sub>4</sub> (1+1) and 2 mL 20% Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O soln, and proceed as in 16.030.

If sample contains HOAc added in course of manufacture (e.g., catsup), transfer extd material, after evapn of ether, to beaker, add ca 50 mL H<sub>2</sub>O, and evap. to 20 mL. Again add 50 mL H<sub>2</sub>O and evap. to 20 mL. Neutze with satd Ba(OH)<sub>2</sub> soln and proceed as in 16.031.

##### 32.042 ★ Field Corn in Canned Mixtures ★ of Field and Sweet Corn (11) Official Final Action

See 30.016, 10th ed.

#### DRIED VEGETABLES

##### Water (12)—Official Final Action

(Dry all glassware in oven.)

##### 32.043

##### Preparation of Sample

Grind sample to pass No. 30 sieve and store in tightly sealed container.

★ Surplus method—see inside front cover.

#### Near-Infrared Spectrophotometric Method

(Caution: See 51.053.)

##### 32.044

##### Apparatus

*Spectrophotometer*.—Beckman Instruments DK2A, or equiv., near-IR recording instrument.

##### 32.045

##### Preparation of Standard Curve

Accurately weigh 200, 300, 400, 500, and 600 mg H<sub>2</sub>O into sep. 125 mL g-s erlenmeyers. Pipet 100 mL *N,N*-dimethylformamide (DMF) into each flask. Record *A* of solns in matched quartz or silica cells from 1.8 to 2.1  $\mu\text{m}$ , using for ref. same lot DMF as used for prepn of std solns. Draw baseline between minima at ca 1.82  $\mu\text{m}$  and 2.0  $\mu\text{m}$ . *A* of std soln at max., ca 1.92  $\mu\text{m}$  = total *A* at max. – baseline *A* at max. Plot corrected baseline *A* against mg H<sub>2</sub>O/100 mL DMF.

##### 32.046

##### Determination

Accurately weigh sample contg ca 70–100 mg H<sub>2</sub>O into 50 mL g-s erlenmeyer. Pipet in 20 mL DMF. Tape stopper securely to flask and heat 60 $\pm$ 1 min at 90 $\pm$ 1° in oven. Mech. shake flask 10 min. Cool to room temp. Decant soln into g-s centrf. tube and centrf. at 1500 rpm until soln is clear (ca 5 min). Record *A* of soln and calc. *A* at max. as in 32.045.

$$\% \text{ H}_2\text{O} = (\text{mg H}_2\text{O from std curve} \times 100) / (5 \times \text{mg sample})$$

#### Karl Fischer Method

##### 32.047

##### Apparatus

*Titrimeter*.—Fisher Scientific Co. Model 36, Manual K-F Titrimeter, or equiv., with 2 Pt electrodes. See 31.068.

##### 32.048

##### Reagents

(a) *Karl Fischer reagent*.—Stabilized, with H<sub>2</sub>O equiv. of ca 5 mg H<sub>2</sub>O/mL reagent. Available com. or prep. as in 31.069(a), using ethylene glycol monomethyl ether. Place 50 mL formamide, practical grade, into 200 mL Berzelius beaker contg mag. stirrer. Place in titrimeter and titr. (Titr. slowly near end point until 0.1 mL addn causes meter to deflect to right of 0 and remain 60 sec.) Quickly add accurately weighed amt (0.250–0.350 g) disodium tartrate·2H<sub>2</sub>O. Titr. immediately to same end point. Repeat detn and calc. av.

$$\text{mg H}_2\text{O/mL reagent} = (\text{mg Na}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}_2\text{O} \times 0.1566) / \text{mL reagent}.$$

(b) *Sodium tartrate dihydrate*.—"60 mesh."

##### 32.049

##### Determination

Accurately weigh 2.0–2.5 g sample into 50 mL g-s erlenmeyer. Pipet in 20 mL *N,N*-dimethylformamide (DMF). Ext and centrf. as in 32.046.

Place 50 mL formamide into 200 mL Berzelius beaker and titr. to end point as in stdzg Karl Fischer reagent. Quickly pipet 10 mL sample soln into beaker and titr. to same end point. Det. blank by titrg 10 mL DMF in same manner as sample. Repeat blank detn and calc. av.

$$\% \text{ H}_2\text{O in sample} = [200 (\text{mL reagent for sample} - \text{blank titer}) (\text{mg H}_2\text{O/mL reagent})] / \text{mg sample}.$$

## FROZEN VEGETABLES

Net Contents of Frozen Food Containers  
(13)—Procedure

32.050

## Apparatus

(a) *For packages up to 5 pounds.*—Use scale of adequate capacity with sensitivity of 0.01 oz.

(b) *For packages over 5 pounds.*—Use scale of adequate capacity with sensitivity of 0.025 oz.

32.051

## Procedure

Set scale on firm support and level. Adjust 0 load indicator or rest point and check sensitivity.

(a) *Unglazed frozen foods.*—Remove package from low temp. storage, remove frost and ice from outside of package, and weigh immediately ( $W$ ). Open package; remove contents, including any product particles and frost crystals. Air-dry empty package at room temp. and weigh ( $E$ ). Wt contents =  $W - E$ .

(b) *Glazed frozen foods.*—See 18.001(a).

32.052 Thawing Frozen Vegetables (14)—Procedure

## (FAO/WHO Method)

See 22.006. Use (a), (b), or following, as appropriate to product; e.g., for corn, use air thawing or indirect contact to avoid leaching solids. Do not use direct contact if there is indication of off flavors or odors.

*Direct contact thawing.*—(Applicable to vegetables having few cut surfaces such as brussels sprouts, asparagus, or green beans.) Remove product from package and immerse in  $H_2O$  at  $\leq 30^\circ$ . As soon as individual units can be sepd, drain on screen to remove excess  $H_2O$ , and place on tray for air thawing and examination.

Total Solids in Frozen Spinach (15)  
Official Final Action

32.053

## Apparatus

(a) *Drying dish.*—Al, with tight-fitting cover, 33 × 70 mm id.

(b) *Drying oven.*—Mech. air circulation or gravity convection, 105°.

32.054

## Preparation of Sample

Transfer frozen contents of package, including any product particles and frost crystals, to 2 L beaker. Cover with plastic wrap to prevent evapn and thaw by placing beaker in ca 30°  $H_2O$  bath. Transfer contents to high-speed blender and reduce to smooth, uniform puree while stirring constantly with rubber spatula to maintain proper action of blender. Return blended sample to original beaker and stir to pick up residual  $H_2O$ . Transfer ca 200 g sample to small, sealed container for analysis.

32.055

## Determination

Add ca 15 mg diat. earth filter-aid/sq cm to drying dish. Dry ca 1 hr at 105°, cool in desiccator, and weigh. Add amt sample so dry residue will be >12 but <30 mg/sq cm. Weigh as rapidly as possible to avoid moisture loss. Mix with filter-aid and distribute slurry uniformly over bottom of dish; dil. with  $H_2O$  if necessary to aid distribution. Wash solids on stirring rod into dish. Dry sample by one of following methods:

(a) Place sample in 105° oven with mech. air circulation and provision for interchange with outside air to remove moisture. Dry 4 hr and weigh. Repeat drying and weighing until wt loss in 1 hr drying is  $\leq 1$  mg.

(b) Place sample in 105° gravity convection oven. Monitor

temp. at point near air outlet where temp. will gradually rise at rate proportional to load in oven. When temp. reaches 100° (4–6 hr), continue heating 1 hr and weigh. Repeat drying and weighing as in (a).

When dry, quickly remove dish from oven, cover, and place in desiccator to cool. Weigh as soon as possible after sample reaches room temp.

$$\% \text{ Solids} = [(W_3 - W_1) \times 100] / (W_2 - W_1),$$

where  $W_1$  = tare wt of dish and diat. earth,  $W_2$  = wt of dish and wet sample, and  $W_3$  = wt of dish and dried sample.

Alcohol-Insoluble Solids in Frozen Peas (16)  
Official Final Action

32.056

## Reagents and Apparatus

(a) *Alcohol solns.*—(1) *Extracting soln.*—SDA 3-A (5% MeOH) or reagent (3-A—isopropanol (95+5)). (2) *Washing soln.*—80%. Dil. 8 L 3-A or reagent alcohol to 9.5 L with  $H_2O$ .

(b) *Drying dish.*—Flat-bottom, with tight-fitting cover.

(c) *Drying oven.*—Well ventilated, thermostatically controlled at  $100 \pm 2^\circ$ .

32.057

## Preparation of Sample

Transfer frozen contents of package to plastic bag; tie bag securely and immerse in  $H_2O$  bath with continuous flow at room temp. Avoid agitation of bag during thawing by using clamps or wts. When sample completely thaws, remove bag, blot off adhering  $H_2O$ , and transfer peas to No. 8 sieve, using 8" (20 cm) for container <3 lb (1.36 kg) net wt and 12" (30 cm) for larger amts. If sauce is present, remove with gentle  $H_2O$  spray at room temp. Without shifting peas, incline sieve to aid drainage; drain 2 min. With cloth, wipe surplus  $H_2O$  from lower screen surface. Weigh 250 g peas into high-speed blender, add 250 g  $H_2O$ , and blend to smooth paste. For <250 g sample, use entire sample with equal wt  $H_2O$ .

32.058

## Determination

Weigh 20 g  $\pm 10$  mg paste into 250 mL distn flask, add 120 mL extg soln, and reflux 30 min on steam or  $H_2O$  bath or hot plate. Fit buchner with paper of appropriate size (previously prepd by drying in flat-bottom dish 2 hr at 100°, covering with tight-fit cover, cooling in desiccator, and weighing). Apply vac. and transfer flask contents to buchner so as to avoid running over edge of paper. Suck dry and wash material on filter with 80% alcohol until washings are clear and colorless.

Transfer paper and alcohol-insol. solids to dish used to prep. paper, dry uncovered 2 hr at 100°, cover tightly, cool in desiccator, and weigh at once. From this wt deduct wt dish, cover, and paper. Calc. % by wt of alcohol-insol. solids.

Fibrous Material in Frozen Green Beans (17)  
Official Final Action

32.059

## Apparatus

(a) *Mixer.*—Overhead rotor, drink mixer type with 2 scalloped buttons 2.5 cm diam., spaced ca 2.5 cm apart on mixer spindle. No-load rating  $\geq 12,000$  rpm. Equipped with metal mixer cup.

(b) *Macerating plunger rod.*—No. 7 rubber stopper attached with flat head screw, in inverted position, to end of 0.5" (12.7 mm) wood dowel, 25–30 cm long.

(c) *Fiber sieve assembly.*—Fit 85 mm diam. stainless steel or Monel screen, 30 mesh (595  $\mu$ m) 32 gage, to wide mouth Mason jar closure ring. Attach to glass funnel prepd by cutting off bottom half of wide mouth Mason jar, leaving ca 12 cm side on closure side.

(d) *Fiber washing assembly*.—Glass tube nozzle 75 mm (3") long  $\times$  3 mm ( $\frac{1}{8}$ ") id inserted into rubber hose  $\leq$  6 mm ( $\frac{1}{4}$ ") id which is connected to H<sub>2</sub>O source at controlled pressure such that assembly will deliver H<sub>2</sub>O from nozzle at  $1650 \pm 50$  mL/min.

**32.060****Preparation of Sample**

Place  $\geq 250$  g (9 oz) sample on  $\geq 8$ " No. 8 sieve and place under gentle stream of H<sub>2</sub>O (30–40°) to thaw bean units and wash away any sauce. Remove any extraneous material, including stem end of any unsnipped bean unit.

Place thawed sample in utensil with enough boiling H<sub>2</sub>O to cover. Cover utensil and boil 15 min after H<sub>2</sub>O returns to boil. Drain on No. 8 sieve, cool to room temp. under cold H<sub>2</sub>O, and drain.

**32.061****Determination**

Place ca 250 g cooked sample on tray, break open pods, and remove and discard seeds. Collect on sieve, to permit drainage, enough pods to provide 200 g sample. Cover accumulated pods to prevent drying.

Prep. several clean fiber sieves before starting detn. Remove each used screen from ring, brush with stiff bristle brush to loosen fibrous residue, and rinse under stream of H<sub>2</sub>O. Reset in ring, dry 1 hr at 100°, cool in desiccator, and weigh to 0.2 mg (T g).

Transfer  $200 \pm 0.5$  g deseeded beans to mixer cup and mash with plunger rod. Remove rod and wash adhering material into cup with 275 mL hot H<sub>2</sub>O. Heat almost to bp, carefully add 40 mL 50% (w/w) NaOH soln, with stirring, and bring to boil, adding  $\leq 1$  mL capryl alcohol if necessary to control foaming. Boil 5 min, in fume hood, stirring occasionally.

Transfer cup to mixer and stir 5 min at speed  $\geq 9000$  rpm that does not cause spillage. (Control speed with variable transformer set at 80–90 v, measured with voltmeter.) Add capryl alcohol dropwise as necessary to control foaming. Sample spillage may be prevented by use of large polyethylene funnel with stem removed to pass mixer spindle and with notch at upper cup bracket so that funnel rests on rim of mixer cup.

Attach weighed screen and ring assembly to glass funnel to provide tight joint. Place on ring clamp, and pour mixt. from cup slowly thru screen, washing simultaneously with moving stream of H<sub>2</sub>O from washing assembly until mat is free from pulp. Transfer funnel assembly to warm H<sub>2</sub>O bath to leach remaining NaOH. Return funnel assembly to ring and place few drops phthln on mat. If red color develops, continue washing until alk.-free.

Detach funnel and rest ring and sieve against side wall of a tray to let H<sub>2</sub>O drain. Place ring and sieve assembly in 100° oven, providing free circulation of air thru screen. Dry 3 hr at 100°; cool 15 min in desiccator contg fresh 8–20 mesh CaCl<sub>2</sub>, CaSO<sub>4</sub>, or silica gel. Weigh rapidly to 0.5 mg (W g).

% Fibrous material =  $(W - T) \times 100/\text{g sample}$ .

Report results to 0.001%.

**Aldehydes as Acetaldehyde (18)—Official First Action****32.062****Apparatus**

*Steam distilling apparatus*.—Consists of 500 mL Kjeldahl flask, spray trap, and condenser, preferably all-glass with  $\frac{1}{8}$  joints (Cat. No. JD 1710, SGA Scientific, Inc., is satisfactory). App. with rubber stoppers and connections is suitable if satisfactory blanks are obtained. (Some rubber yields neg. blanks.)

**32.063****Reagents**

(a) *Sodium thiosulfate std soln*.—0.05N. Prep. daily by dilg 0.1N soln, **50.037–50.038**. 1 mL 0.05N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 1.1 mg AcH.

(b) *Iodine std soln*.—0.05–0.0515N. Prep. as in **50.018**, stdze against Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, (a), and adjust concn, if necessary.

(c) *Sodium bisulfite std soln*.—0.05N in ca 10% alcohol. Dissolve 2.60 g NaHSO<sub>3</sub> in 500 mL H<sub>2</sub>O in 1 L vol. flask. Add 100 mL alcohol, mix, and dil. to vol. with H<sub>2</sub>O. Stdze against I soln, (b), and adjust concn, if necessary, so as to be slightly weaker than that of the I soln, but not  $< 0.0485N$ . Prep. fresh daily.

(d) *Aldehyde-free alcohol*.—Use alcohol contg  $< 2$  ppm AcH; if greater, purify as in **19.071(a)**. Det. aldehydes as in **32.064**, using 300 mL freshly boiled and cooled H<sub>2</sub>O and 35 mL of the alcohol, beginning "Pipet in 25 mL NaHSO<sub>3</sub> soln . . ." Det. blank similarly but without alcohol. Difference in titrns  $\times 31$  = ppm aldehydes as  $\lambda\text{CH}$ .

**32.064****Determination**

Sharply strike package of frozen vegetable on surface or edge of table to break up block. Mix well and grind ca 150 g thru food chopper.

Transfer 50 g sample to Kjeldahl flask with ca 150 mL H<sub>2</sub>O. Add 1–2 drops *Dow-Corning Antifoam*, or equiv., and steam distil into 500 mL erlenmeyer, immersed in ice bath and contg 100 mL chilled, freshly boiled H<sub>2</sub>O to cover end of delivery tube. Collect ca .00 mL within 12–15 min. To distillate add 35 mL aldehyde-free alcohol. Pipet in 25 mL NaHSO<sub>3</sub> soln and let stand 30 min, shaking occasionally. Pipet in 25 mL I soln, and titr. with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, using 5 mL starch indicator, **32.065(g)**. Det. blank on 300 mL freshly boiled and cooled H<sub>2</sub>O. Difference in mL  $\times 1.1$  = mg AcH; mg AcH  $\times 1000/\text{wt sample}$  = ppm.

**Catalase (19)—Official First Action****32.065****Reagents***Relatively Stable Reagents*

(a) *Phosphate buffer soln*.—0.1M, pH  $6.95 \pm 0.15$ . Dissolve 15.22 g K<sub>2</sub>HPO<sub>4</sub>·3H<sub>2</sub>O and 4.54 g KH<sub>2</sub>PO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L.

(b) *Sulfuric acid containing molybdate*.—2N. Add 55 mL H<sub>2</sub>SO<sub>4</sub> to ca 800 mL H<sub>2</sub>O, cool, add 0.1 g finely ground (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub>·4H<sub>2</sub>O, agitate until completely dissolved, and dil. to 1 L with H<sub>2</sub>O.

(c) *Sodium thiosulfate (ca 0.01N) in 10% potassium iodide soln*.—Dissolve 100 g KI, 2.50 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O, and ca 1 g Na<sub>2</sub>CO<sub>3</sub> in 500 mL H<sub>2</sub>O and dil. to 1 L. (Need not be stdzd.)

(d) *Iodine std soln*.—0.01N. Prep. as in **50.018**. Stdze against std Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, **50.037–50.038**. (Avoid exposure to excessive light even while in buret.)

*Relatively Unstable Reagents*

(e) *Hydrogen peroxide*.—0.1N. Dil. 0.58 mL 30% H<sub>2</sub>O<sub>2</sub> to 100 mL with cold H<sub>2</sub>O. Keep in refrigerator or ice bath when not in use. Prep. daily.

(f) *20% soln of glucose in buffer soln*.—Dissolve 20 g glucose in 100 mL phosphate buffer soln, (a). Keep refrigerated and prep. weekly.

(g) *Starch indicator*.—Add 1.0 g sol. starch to 100 mL cold H<sub>2</sub>O, stir thoroly, and heat to boiling. Prep. biweekly.

**32.066****Preparation of Extract**

To avoid contamination with oxides of heavy metals, handle samples only with nonmetallic or stainless steel spatulas.

(a) *Undried or frozen vegetables*.—Comminute 50 g portions in high-speed blender 3 min with ca 1 g CaCO<sub>3</sub> and enough H<sub>2</sub>O

to make total vol. 200 mL. Remove larger particles by filtering thru 15 cm (6") gauze-backed cotton milk filter. Assay filtrate within 30 min.

(b) *Dried vegetables*.—Rehydrate 5 g sample and ext as in (a).

**32.067****Determination**

(a) *To demonstrate presence or absence of catalase*.—To 10 mL ext (or less, depending on activity) add H<sub>2</sub>O to total vol. of 43 mL and 5 mL glucose soln, (f). Mix, and add 2 mL 0.1*N* H<sub>2</sub>O<sub>2</sub>. Immediately after addn of H<sub>2</sub>O<sub>2</sub>, mix thoroly, quickly remove "0-time" aliquot of completed reaction mixt. with rapid-flow pipet, and blow it into 125 mL erlenmeyer contg 10 mL H<sub>2</sub>SO<sub>4</sub>-molybdate soln. Count "0-time" from time delivery of aliquot from pipet is started. Remove 10 mL aliquots at 5 and 10 min. (Temp. of reaction mixt. must remain at <20°.) At any time within 1 hr add 5 mL Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>-KI soln to each flask and mix. Let stand 3–5 min; then titr. excess Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> with 0.01*N* I, using ca 10 drops starch indicator.

Perform blank in exactly same manner, except add H<sub>2</sub>O instead of H<sub>2</sub>O<sub>2</sub>, and do not remove 5 and 10 min aliquots. Differences between titer value of blank and of values obtained in presence of H<sub>2</sub>O<sub>2</sub> are 1 soln equivs of H<sub>2</sub>O<sub>2</sub> present at respective times. "Zero-time" titer value should be 0.5–2 mL I soln; differences between blank-titer value and "0-time" titer value should be 3.0–4.5 mL 0.01*N* I. Difference of <3.0 mL (*i.e.*, 1 titer values >2 mL) indicates that the H<sub>2</sub>O<sub>2</sub> was too weak or that catalase activity was so high that large amt of H<sub>2</sub>O<sub>2</sub> was decomposed before "0-time" aliquot was removed. In latter case, differences corresponding to 5 and 10 min may be nearly 0, even when large amts of catalase are present. In such case, catalase content of ext can be detd by method (b), if desired. If 10 mL aliquots of ext are used, blank-titer value is 4–6 mL, and "0-time" titer value is <2 mL, catalase is indicated to be absent (within experimental error) when titer values for 5 and 10 min do not differ from "0-time" titer value by >0.20 mL and 0.40 mL, resp.

(b) *To accurately determine catalase activity of sample in terms of K<sub>t</sub>*.—"Katalase Fähigkeit," K<sub>t</sub> is *k*, first order reaction const (log base 10) detd at 0°, divided by g sample/50 mL reaction mixt. That is, K<sub>t</sub> = *k*/g, and is therefore expression of catalase activity of prepn. Pure catalase has K<sub>t</sub> of 40,000–60,000, depending on source. If K<sub>t</sub> is to be detd, make assay exactly as in (a), except maintain reaction mixt. at 0°. It is generally desirable to obtain 15 min titer value in addn to those described in (a). If sample is enzyme prepn of high activity rather than a vegetable, dissolve suitable amt in dil. buffer, pH 6.5–7.5, preferably contg 2% glucose.

**32.068****Calculation of K<sub>t</sub>**

Value for K<sub>t</sub> for 0–5 min and 5–10 min periods should check at 0°, but at higher temps K<sub>t</sub> (5–10 min) may be <K<sub>t</sub> (0–5 min), because catalase is inactivated by H<sub>2</sub>O<sub>2</sub> at significant rate at higher temps. K<sub>t</sub> is given by following formula:

$$K_t = \frac{\left(\frac{1}{t_b - t_a}\right) \log \left(\frac{\text{blank titer} - \text{titer at } t_a}{\text{blank titer} - \text{titer at } t_b}\right)}{\text{g sample/50 mL reaction mixt.}}$$

where *t<sub>a</sub>* and *t<sub>b</sub>* are initial and final times for 2 titer values under consideration. For exts of undried vegetables prepd as in **32.066**, the g sample in reaction mixt. is obtained with enough accuracy by multiplying mL ext used by 0.25. For most nearly accurate results, enzyme concn should be adjusted so that difference between blank titrn and *t<sub>0</sub>* titrn is 3–4 mL, and difference between blank titrn and *t<sub>10</sub>* titrn is 0.5–1 mL I soln.

**Peroxidase (20)—Official Final Action****32.069****Reagents***Relatively Stable Reagents*

(a) *Phosphate-oxalate buffer soln.*—0.1*M*, pH 6.0. Dissolve 14.2 g Na<sub>2</sub>HPO<sub>4</sub> (or 26.81 g Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O) and 12.6 g H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O in H<sub>2</sub>O with heat, cool, adjust pH to 6.0 with 1*N* NaOH, and dil. to 1 L.

(b) *Oxalic acid soln.*—1*M*. Dissolve 126 g H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(c) *Sodium chloride soln.*—2.0%. Dissolve 20 g NaCl in H<sub>2</sub>O and dil. to 1 L. Cool to 0° and store at 0°.

*Relatively Unstable Reagents*

(d) *Hydrogen peroxide soln.*—0.1*N*. Dil. 0.58 mL 30% H<sub>2</sub>O<sub>2</sub> to 100 mL with cold H<sub>2</sub>O. Stdze iodometrically as follows: To 25 mL 0.1*N* H<sub>2</sub>O<sub>2</sub> add 10 mL 4*N* H<sub>2</sub>SO<sub>4</sub>, 6 mL 1*N* KI, and 3 drops 1*N* (NH<sub>4</sub>)<sub>2</sub>Mo<sub>7</sub>O<sub>24</sub>. Titr. soln with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> to starch end point. Store in refrigerator when not in use. Prep. weekly.

(e) *Indophenol soln.*—0.001*N*. Dissolve 200 mg 2,6-dichloroindophenol (LaMotte Chemical Products Co., Chestertown, MD 21620) or 175 mg Na salt (Eastman Kodak Co.), or equivs, in H<sub>2</sub>O and dil. to 1 L. Stdze against 0.01*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> by titrg I liberated by 50 mL dye after addn of 10 mL 1*N* KI and 10 mL 4*N* H<sub>2</sub>SO<sub>4</sub>. Store in refrigerator. Prep. weekly.

(f) *Ascorbic acid soln.*—0.05*M*. Dissolve 880 mg L-ascorbic acid in 0.1*M* buffer, (a), and dil. to 100 mL. Prep. daily.

**32.070****Preparation of Extract**

Comminute 50 g portions fresh or frozen vegetable tissue in high-speed blender with 200 mL cold 2% NaCl soln. Remove larger particles by filtering thru 15 cm (6") gauze-backed cotton milk filter. Assay filtrate within 30 min.

**32.071****Determination**

Into 400 mL beaker place 75 mL buffer, (a), 50 mL dye, 5 mL ascorbic acid, and enough H<sub>2</sub>O to make total vol. of 250 mL after addn of tissue ext and H<sub>2</sub>O<sub>2</sub>. Adjust to 25±0.5° by warming or cooling as necessary. Place beaker on mag. stirrer and stir mixt. 30 sec at speed just below that which would cause excessive aeration. From pipet add 1–3 mL ext (equiv. to 0.2–0.4 g tissue) and rapidly add 5 mL H<sub>2</sub>O<sub>2</sub> from blowout pipet. Start stopwatch immediately on addn of H<sub>2</sub>O<sub>2</sub>. Continue mixing during addn of H<sub>2</sub>O<sub>2</sub> and until first aliquot is removed.

Within 15–30 sec after adding H<sub>2</sub>O<sub>2</sub>, remove 25 mL aliquot of reaction mixt. with 25 mL rapid-flow pipet adjusted to empty by blowing out in 5 sec, and discharge into 5 mL oxalic acid soln in 125 mL erlenmeyer. Take 4–5 subsequent samples at 1 min intervals and blow out into other 125 mL flasks each contg 5 mL oxalic acid soln. Record time as time pipet is emptied. Titr. residual ascorbic acid with dye soln and calc. first order reaction rate const. Adjust enzyme activity so that const is of order of magnitude of 15–20 × 10<sup>-2</sup> and express peroxidase activity, K<sub>t</sub>, as K<sub>t</sub>/g tissue used. Perform all titrns beyond fading end point to clearly visible pink, permanent 1 min. Adjust all titrns to same end point by comparison with first flask of each series. Add dye rapidly at first and more slowly later.

**32.072****Calculation of K<sub>t</sub> and K<sub>i</sub>**

Under optimal conditions, initial titrn value is 35–40 mL dye and subsequent titrn values decrease to 20–25 mL in 5 min. Calc. first order reaction rate const as for catalase, **32.068**, or take from slope of plot of log mL dye against time. Divide av. K<sub>t</sub> value for several intervals of time (0–1, 1–2, 2–3 min) by wt of vegetable tissue corresponding to vol. of ext in reaction mixt.

## 33. Waters; and Salt

### WATER

#### 33.001 Specific Gravity—Official Final Action

Det. sp gr at 20/20°, using pycnometer, as in 9.011.

#### Specific Conductance (1, 2)

#### 33.002

#### Principle

Conductivity of sample is compared with that of std KCl soln. Method is applicable to drinking, surface, and saline waters, and domestic and industrial wastes.

Synthetic H<sub>2</sub>O samples contg increments of inorg. salts analyzed by 41 analysts in 17 laboratories showed following results:

Increment as sp conductance, μmhos/cm	Std deviation		Bias	
	%	μmhos/cm	%	μmhos/cm
100	7.6	7.55	-2.0	- 2.0
106	7.7	8.14	-0.8	- 0.8
808	7.5	66.1	-3.6	-29.3
848	9.4	79.6	-4.5	-38.5
1640	6.5	106	-5.4	-87.9
1710	7.0	119	-5.1	-86.9

#### 33.003

#### Apparatus and Reagent

(a) *Conductivity meter.*—Self-contained, Wheatstone bridge-type, capable of being read to ±1%.

(b) *Specific conductance cell.*—Choose cell according to expected sp conductance so that measured cell resistance is 500–10,000 ohms. Cell const should be ca 0.1 for solns of low conductivity (<100 μmhos), 1 for moderate, and 10 for highly conducting, such as brines. Check complete assembly with KCl solns of known conductance shown in Table 33:01. Clean new cells with chromic acid cleaning soln and platinize new electrodes before use. Reclean and platinize electrodes whenever readings become erratic or if inspection shows any Pt black has flaked off. To platinize, connect both electrodes together to neg. terminal of 1.5 v dry cell and immerse in soln of 1 g chloroplatinic acid and 12 mg Pb(OAc)<sub>2</sub> in 100 mL H<sub>2</sub>O. Connect pos. terminal to piece of Pt wire and dip into soln. Control current so that only small amt gas is evolved. Discontinue electrolysis when both electrodes are coated. Soln may be saved for subsequent use. Rinse electrodes thoroly and keep immersed in H<sub>2</sub>O when not in use.

(c) *Potassium chloride std soln.*—0.01M. Dissolve 745.6 mg KCl in freshly boiled double-distd H<sub>2</sub>O and dil. to 1 L at 25°. Soln has sp conductance of 1413 μmhos at 25°. It is satisfactory for most waters when using cell with const of 1–2. With other cells, use soln in Table 33:01 and corresponding sp conductance in calcn. Store in g-s Pyrex bottle.

#### 33.004

#### Determination

Temp. must be const thruout detn since sp conductance varies ca 2%/degree. Use 25° if possible; otherwise use near room temp. but between 20–30°.

Place 4 tubes std KCl soln and 2 tubes of each sample in H<sub>2</sub>O bath and let stand 30 min. Rinse cell in 3 tubes of KCl soln and measure resistance of soln 4,  $R_{KCl}$ . Rinse cell thoroly with tube 1 of sample and measure resistance of tube 2,  $R_s$ . Do not repeat measurement of KCl soln unless temp. drift of more than few tenths degree occurs. If samples differ in conductivity by factor

of ≥5, minimize carry-over by rinsing in 2 tubes of sample and measuring third.

#### 33.005

#### Calculation

Calc. cell const,  $C$ , in mhos/cm =  $R_{KCl} \times 0.001413$  at 25°. Specific conductance of sample at 25° =  $C/R_s$  in mhos/cm. Multiply by 10<sup>6</sup> to obtain μmhos/cm.

If temp. is not exactly 25°, measure  $R_{KCl}$  and  $R_s$  at same temp. and calc. sp conductance =  $1413 \times R_{KCl}/R_s$  in μmhos/cm.

#### pH (1, 2)

#### 33.006

#### Principle

pH, which is accepted measure of acidity or alky, is detd by change in potential of glass-satd calomel electrodes, as measured by com. app. stdzd against std buffer solns whose pH values are assigned by NBS. pH of most natural H<sub>2</sub>O falls within 4–9. Majority of waters are slightly basic from presence of CO<sub>3</sub>-HCO<sub>3</sub> system.

Table 33:01 Conductances of KCl Solns at 25°

Concn, M	Conductance, μmhos/cm	
	Equiv.	Specific
0	149.85	
0.0001	149.43	14.94
0.0005	147.81	73.90
0.001	146.95	147.0
0.005	143.55	717.8
0.01	141.27	1,413
0.02	138.34	2,767
0.05	133.37	6,668
0.1	128.96	12,900
0.2	124.08	24,820
0.5	117.27	58,640
1.0	111.87	111,900

Method is applicable to drinking, surface, and saline waters, and domestic and industrial wastes. Oils and greases, by coating electrodes, may cause sluggish response.

Buffered synthetic H<sub>2</sub>O samples analyzed by 44 analysts in 20 laboratories showed following results:

pH	Std deviation, pH units	
	Bias, pH units	
3.5	0.10	-0.01
3.5	0.11	0.00
7.1	0.20	+0.07
7.2	0.18	-0.002
8.0	0.13	-0.01
8.0	0.12	+0.01

#### 33.007

#### Apparatus and Reagent

(a) *pH meter.*—Com. instrument with flow-type electrodes (preferred for relatively unbuffered samples such as condensates) or immersion electrodes. Operate in accordance with manufacturer's instructions.

(b) *Std buffer solns.*—See 50.007 and Table 50:02.

#### 33.008

#### Determination

Thoroly wet electrodes and prep. in accordance with manufacturer's instructions. Stdze instrument with std buffer with pH

near that of sample and then with 2 others to check linearity of electrode response.

Analyze sample as soon as possible, preferably within few hr. Do not open sample bottle before analysis. With immersion electrodes, wash 6–8 times with portions of sample, particularly when unbuffered soln follows buffered soln. Equilibrium, as shown by absence of drift, must be established before readings are accepted.

### Acidity (1, 2)

#### 33.009

#### Principle

Sample is titrd to pH 8.3, using phthln as indicator, and results are reported as mg  $\text{CaCO}_3/\text{L}$ . Method is applicable to drinking and surface waters, domestic and industrial wastes, and saline waters. Synthetic  $\text{H}_2\text{O}$  contg increments of  $\text{HCO}_3^-$  analyzed by 40 analysts in 17 laboratories showed following results:

Added, mg $\text{CaCO}_3/\text{L}$	Std deviation		Bias	
	%	mg $\text{CaCO}_3/\text{L}$	%	mg $\text{CaCO}_3/\text{L}$
20	9.0	1.79	+2.8	+0.55
21	8.2	1.73	+0.5	+0.11

#### 33.010

#### Apparatus

(a) *Illumination*.—Daytime fluorescent lamps provide uniform lighting conditions.

(b) *Potentiometric equipment*.—Automatic titrators and pH meters, suitably calibrated, may be substituted for visual titrn and end point.

#### 33.011

#### Reagents

(a) *Carbon dioxide-free water*.—If pH is <6.0, prep. as in 50.033(a). Deionized  $\text{H}_2\text{O}$  may be substituted if conductance is <2  $\mu\text{mhos}/\text{cm}$  and pH >6.0.

(b) *Sodium hydroxide std soln*.—0.02N. Dil. 20.0 mL 1N NaOH with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$  to 1 L. Store in tightly stoppered Pyrex bottle protected by soda-lime tube. Prep. weekly. Stdze against 0.0200N KH phthalate soln (4.085 g/L) or against stdzd 0.02N HCl or  $\text{H}_2\text{SO}_4$ . Use vol. soln to give acidity approx. that of samples titrd, dild to vol. of sample, with same vol. indicator, and same time intervals as in detn. 1 mL 0.0200N NaOH = 1.00 mg  $\text{CaCO}_3/1.00$  mL.

#### 33.012

#### Preparation of Samples

Collect and store samples in Pyrex or polyethylene bottles. Refrigerate at 4° and perform detn as soon as possible, preferably within 24 hr.

#### 33.013

#### Determination

Use sample vol. requiring <25 mL titrant. If indicator is used, remove free Cl with 1 drop 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , 50.037.

To 50 or 100 mL sample in white porcelain casserole or in erlenmeyer over white surface, add 0.15 mL phthln. Tit. with stdzd 0.02N NaOH to faint pink (pH 8.3).

$\text{mg CaCO}_3/\text{L} = \text{mL NaOH} \times \text{normality NaOH} \times 50,000/\text{mL sample}$ .

### Alkalinity (1, 2)

#### 33.014

#### Principle

Unaltered (undild, unconcd, unfiltered) sample is titrd potentiometrically to pH 4.5. Applicable to drinking and surface waters, domestic and industrial wastes, and saline waters. Suitable for all concn ranges.

Synthetic  $\text{H}_2\text{O}$  contg increments of  $\text{HCO}_3^-$  analyzed by 40 analysts in 17 laboratories showed following results:

Added, mg $\text{CaCO}_3/\text{L}$	Std deviation		Bias	
	%	mg $\text{CaCO}_3/\text{L}$	%	mg $\text{CaCO}_3/\text{L}$
8	16	1.3	+10.6	+0.85
9	12	1.1	+22.3	+2.0
113	4.7	5.3	– 8.2	–9.3
119	4.5	5.4	– 7.4	–8.8

#### 33.015

#### Apparatus

See 33.010(b).

#### 33.016

#### Reagents

(a) *Carbon dioxide-free water*.—See 33.011(a).

(b) *Acid std soln*.—0.02N. Prep. ca 0.1N stock soln by dild 8.3 mL HCl or 2.8 mL  $\text{H}_2\text{SO}_4$  to 1 L. Dil. 200 mL stock soln to 1 L with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ . Stdze against 0.02N  $\text{Na}_2\text{CO}_3$  (1.060 g  $\text{Na}_2\text{CO}_3/\text{L}$ , 50.016(c)) or stdzd 0.02N NaOH, 33.011(b). Use vol. soln to give alky approx. that of samples titrd, dild to vol. of sample, with same vol. indicator and same time intervals as in detn. 1 mL 0.02N acid = 1.00 mg  $\text{CaCO}_3/\text{L}$ .

#### 33.017

#### Preparation of Samples

See 33.012.

#### 33.018

#### Determination

Use sample vol. requiring <25 mL titrant. Tit. potentiometrically to pH 4.5.

$\text{mg CaCO}_3/\text{L} = \text{mL acid} \times \text{normality acid} \times 50,000/\text{mL sample}$ .

### Biochemical Oxygen Demand (BOD) (1, 3)

#### 33.019

#### Principle

Sample is incubated 5 days at 20° in presence of acclimated biological system. Comparison of O content of sample at beginning and end of incubation is measure of BOD.

Method is applicable to raw or treated domestic wastes, industrial water, and industrial waste water. Following classes of materials exert O demand: (1) org. material usable as food by aerobic organisms (source of BOD of many waste waters); (2) oxidizable N from nitrites,  $\text{NH}_3$ , and org. N compds which serve as food for specific bacteria (e.g., *Nitrosomonas* and *Nitrobacter*) (a source of some of O demand of biologically treated effluents); (3) chemically oxidizable materials (e.g.,  $\text{Fe}^{+2}$ ,  $\text{S}^{-2}$ ,  $\text{SO}_3^{-2}$ ) (when present, test must be based upon calcd initial dissolved O content).

Many synthetic org. components of industrial wastes are not degraded by common organisms. Without special seeding material, effect is manifested as retardation of aerobic metabolism because of toxic effect or deficiency or absence of appropriate microorganism. Toxic compds in distd  $\text{H}_2\text{O}$ , frequently Cu, may result in low BOD.

Distd  $\text{H}_2\text{O}$  contg known increments of oxidizable org. material analyzed by 74 analysts in 50 laboratories showed following results:

Increment org. material, mg/L	Std deviation		Bias	
	%	mg/L	%	mg/L
2.2	33	0.7	– 4	– 0.08
194	15	26	–10	–19

**33.020****Apparatus**

- (a) *Incubation bottles*.—250 or 300 mL with glass stoppers.  
 (b) *Incubator*.—Air or H<sub>2</sub>O bath maintained at 20±1° and which excludes light. (*Caution*: Check H<sub>2</sub>O bath to assure that it is electrically grounded.)

**33.021****Reagents**

- (a) *Water*.—Contg ≤0.01 mg Cu/L, obtained by double demineralization of distd H<sub>2</sub>O or distn from all-glass or Sn-lined system.  
 (b) *Calcium chloride soln*.—27.5 g anhyd. CaCl<sub>2</sub>/L.  
 (c) *Ferric chloride soln*.—0.25 g FeCl<sub>3</sub>·6H<sub>2</sub>O/L.  
 (d) *Magnesium sulfate soln*.—22.5 g MgSO<sub>4</sub>·7H<sub>2</sub>O/L.  
 (e) *Phosphate buffer soln*.—pH 7.2. Dissolve 8.50 g KH<sub>2</sub>PO<sub>4</sub>, 21.75 g K<sub>2</sub>HPO<sub>4</sub>, 33.40 g Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O, and 1.70 g NH<sub>4</sub>Cl in ca 500 mL H<sub>2</sub>O and dil. to 1 L.  
 (f) *Seeding material*.—Satisfactory seed may sometimes be obtained or developed from supernate of domestic sewage stored 24–36 hr at 20°, from receiving H<sub>2</sub>O downstream from point of discharge, or, in case of industrial wastes contg org. compds not amenable to oxidn by domestic sewage seed, from acclimated seed developed in laboratory.  
 (g) *Sodium hydroxide soln*.—50 g NaOH/L.  
 (h) *Sodium sulfite soln*.—1.575 g Na<sub>2</sub>SO<sub>3</sub>/L. Prep. fresh as needed.

**33.022****Preparation of Dilution Water**

Store H<sub>2</sub>O, **33.021(a)**, in cotton-plugged bottles long enough to sat. with atm. O at 20°, or aerate with air filtered to remove any oil from compressor (≤1 hr may be required for 19 L (5 gal.)). Add desired vol. of O-satd H<sub>2</sub>O to suitable bottle and add 1 mL each of phosphate buffer, MgSO<sub>4</sub>, CaCl<sub>2</sub>, and FeCl<sub>3</sub> solns/L. Seed this diln H<sub>2</sub>O with seeding material and with vol. found by experience to be most satisfactory for particular waste being examined. Use seeded diln H<sub>2</sub>O within 24 hr of prepn.

Periodically check quality of diln H<sub>2</sub>O, effectiveness of seed, and technic with particular org. compd if known to be present in waste or, for general work, with mixt. of glucose and glutamic acid (150 mg each/ L) which should show BOD ca 220±30 mg/L in 95% of detns. Appreciable divergence requires examination of quality of H<sub>2</sub>O, viability of seeding material, or technic.

**33.023****Preparation of Samples**

Keep time between collection of sample and start of analysis to absolute min. Protect samples from atm. O. If necessary, pretreat samples as follows:

- (a) *Acidity or caustic alkalinity*.—Neutze to ca pH 7 with dil. H<sub>2</sub>SO<sub>4</sub> or 5% NaOH, using pH meter or bromothymol blue as external indicator. pH of seeded diln H<sub>2</sub>O should not be changed by diln of sample.

- (b) *Residual chlorine*.—Let stand 1–2 hr to dissipate Cl. If not effective, use Na<sub>2</sub>SO<sub>3</sub> treatment. Det. vol. to be used by adding 10 mL HOAc (1+1) or H<sub>2</sub>SO<sub>4</sub> (1+49) and 10 mL 10% KI to 1 L sample. Titr. to starch-I end point with Na<sub>2</sub>SO<sub>3</sub> soln. Add indicated vol. to sample, and test small portion with starch-I soln to check that treatment is complete.

- (c) *Toxic substances*.—Remove or neutze. Test for toxicity as follows: Add same amt seed to duplicate set of BOD bottles. Add diln H<sub>2</sub>O to each bottle, leaving room for amt of sample to give final concns of 0.06, 0.12, 0.25, 0.50, 1.0, 2.5, 5, 10, 20, and 40%. Neutze sample, add required vol. sample to duplicate bottles, and fill with diln H<sub>2</sub>O. Det. dissolved O in 1 series ca 15 min after prepn of diln. Det. dissolved O in second series after 3 days. Plot consumption of dissolved O against concn. Mag-

nitude of O concn change will depend on amt of food available and toxicity of sample. If toxicity is factor, O consumption will decrease at higher concns.

- (d) *Supersaturation with oxygen*.—Samples contg >9.2 mg O/L at 20° may be encountered during winter or where algae are actively growing. To prevent loss of O during incubation, reduce O content to satn by transferring sample at ca 20° to partially fill bottle and shake vigorously.

**33.024****Determination**

Sample must be dild with seeded diln H<sub>2</sub>O so that at least 1 diln will achieve dissolved O depletion of 1 mg/ L (ppm) during 5 day test period but will not reduce residual dissolved O to <1 mg/L. (Preliminary chemical O demand (COD) detn, **33.034–33.040**, may serve as guide to est. range of BOD.)

Carefully siphon seeded diln H<sub>2</sub>O into 1 or 2 L graduate, filling it ½ full. Add vol. of carefully mixed sample to desired diln and fill to mark with diln H<sub>2</sub>O. Mix well with plunger-type mixing rod, avoiding entrainment of air. If possible BOD range is large, prep. geometric series of dilns to cover possible range. Siphon, with continued mixing, dild sample to completely fill 3 BOD bottles—1 for incubation, 1 for detn of dissolved O content, and 1 for detn of immediate dissolved O demand (IDOD). Insert stoppers without entrainment of any bubbles. Det. dissolved O by method indicated in **33.027**.

Alternatively, prep. dild samples directly by pipetting sample with wide-tip pipet into BOD bottles of known capacity and filling bottles with seeded diln H<sub>2</sub>O. If diln >1:100 is required, prep. in graduate before adding to BOD bottles.

Prep. blank of seeded diln H<sub>2</sub>O contg vol. used for diln of samples for detn of initial dissolved O content. Prep. control of 2 BOD bottles with unseeded diln H<sub>2</sub>O. Stopper and H<sub>2</sub>O-seal 1 bottle for incubation. (If special H<sub>2</sub>O-sealed bottles are not used, H<sub>2</sub>O-seal by immersion in tray of H<sub>2</sub>O.) Det. dissolved O in other bottle before incubation. Quality of unseeded diln H<sub>2</sub>O is satisfactory if depletion obtained is ≤0.2 mg/L, preferably ≤0.1. Do not use this value as blank correction.

If diln H<sub>2</sub>O is seeded, det. O depletion of seed used in such diln that will result in 40–70% depletion in 5 days. Use this depletion, not seeded blank, to calc. correction due to small amt of seed in diln H<sub>2</sub>O.

Incubate prepd mixts, H<sub>2</sub>O-sealed, 5 days at 20±1° and det. final dissolved O content.

**33.025****Calculation**

Calc. in mg/L (ppm) as follows:

Immediate dissolved O demand (IDOD) =  $(D_c - D_1)/P$ .

When seeding is not required, BOD =  $(D_1 - D_2)/P$ .

When using seeded diln H<sub>2</sub>O, BOD =  $[(D_1 - D_2) - (B_1 - B_2)f]/P$ .

Including IDOD, if small or not detd, BOD =  $(D_c - D_2)/P$ .

Where

$D_0$  = dissolved O (DO) of original diln H<sub>2</sub>O,

$D_1$  = DO in dild sample 15 min after prepn,

$D_2$  = DO of dild sample after incubation,

$S$  = DO of original undild sample,

$D_c$  = DO available in diln at zero time =  $(D_0P) + SP$ ,

$p$  = decimal fraction of diln H<sub>2</sub>O used,

$P$  = decimal fraction of sample used,

$B_1$  = DO of the diln of seed control before incubation,

$B_2$  = DO of the diln of seed control after incubation,

$f$  = ratio of seed in sample to seed in control =  $(\% \text{ seed in } D_1)/(\% \text{ seed in } B_1)$ .

**33.026****Interpretation**

Arbitrary std 5 day incubation period is satisfactory measurement of the O load on receiving water for raw or treated

domestic sewage. It may be misleading for wastes contg org. compds not easily amenable to biological oxidn. Studies with 3 incubation periods on series of dilns of the waste will provide information on lag periods, suitability of inocula, rate of biochem. oxidn, ultimate O demand, and amenability to biochem. self-purification. Particularly important is ratio of 5 day BOD to ultimate O demand.

#### Dissolved Oxygen (1)

(Caution: See 51.018.)

#### 33.027

#### Applications

Azide (Alsterberg) method is ordinarily used; it is not affected by most common interference, nitrite, but most other oxidizing or reducing agents should be absent. Effect of  $\text{Fe}^{+3}$  is eliminated with  $\text{F}^-$ . Permanganate (Rideal-Stewart) method is used in presence of  $\text{Fe}^{+2}$  but not org. matter. Pomeroy-Kirshman-Alsterberg method is used for waters supersatd with O or contg high org. matter content.

#### Method I, Azide Method

#### 33.028

#### Reagents

(a) *Alkaline iodide-sodium azide soln.*—Dissolve 500 g NaOH (or 700 g KOH) and 135 g NaI (or 150 g KI) in  $\text{H}_2\text{O}$ , dil. to 950 mL, and cool. Slowly, with stirring, add soln of 10 g  $\text{NaN}_3$  in 40 mL  $\text{H}_2\text{O}$ . Dild and acidified soln must not give color with starch indicator. Store in dark bottle with rubber stopper.

(b) *Manganese sulfate soln.*—Dissolve 364 g  $\text{MnSO}_4 \cdot \text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , filter, and dil. to 1 L. No more than trace of I should be liberated when soln is added to acidified KI soln.

(c) *Potassium biiodate std soln.*—0.025N. Dissolve 0.8125 g  $\text{KH}(\text{IO}_3)_2$  in  $\text{H}_2\text{O}$  in 1 L vol. flask and dil. to vol.

(d) *Potassium fluoride soln.*—40 g  $\text{KF} \cdot 2\text{H}_2\text{O}/100$  mL. (Caution: KF is toxic and corrosive. See 51.084.)

(e) *Sodium thiosulfate std solns.*—(1) 0.1N.—Dissolve 25 g  $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 1 g NaOH or 5 mL  $\text{CHCl}_3$ , and dil. to 1 L. Stdze against  $\text{KH}(\text{IO}_3)_2$  or  $\text{K}_2\text{Cr}_2\text{O}_7$ , 50.038. (2) 0.025N.—Dil. 250 mL 0.1N to 1 L. 1 mL = 0.2 mg O.

(f) *Starch indicator soln.*—Disperse 5–6 g potato or arrowroot starch in mortar with few mL  $\text{H}_2\text{O}$ . Pour into 1 L boiling  $\text{H}_2\text{O}$ , boil few min, and let settle overnight. Decant clear soln and preserve with 1.3 g salicylic acid or few drops toluene.

#### 33.029

#### Determination

(Add all reagents, except  $\text{H}_2\text{SO}_4$ , well below surface of sample from 10 mL pipets graduated in 0.1 mL, with tips elongated ca 50 mm.)

Add 2.0 mL  $\text{MnSO}_4$  soln and 2.0 mL alk. I- $\text{NaN}_3$  soln to sample in 250 or 300 mL BOD bottle, replace stopper, excluding air bubbles, and invert several times to mix. Let floc settle and repeat mixing. (Water with high chloride concn requires 10 min contact with ppt.) After floc has settled, leaving  $\geq 100$  mL clear supernate, remove stopper and add 2.0 mL  $\text{H}_2\text{SO}_4$  down neck of bottle. (If  $>100$  ppm  $\text{Fe}^{+3}$  is present, add 1.0 mL KF soln before acidifying.) Restopper and mix by inversion until  $\text{I}_2$  is uniformly distributed. Immediately titr. 203 mL (3 mL is allowance for added reagents) with 0.025N  $\text{Na}_2\text{S}_2\text{O}_3$  to pale straw yellow. Add 1–2 mL starch indicator and titr. to disappearance of blue. Disregard reappearance of blue.

$\text{ppm dissolved O} = (\text{mL } 0.025\text{N } \text{Na}_2\text{S}_2\text{O}_3 \times 0.2/200) \times 1000.$

#### Method II, Permanganate Method

#### 33.030

#### Reagents

(a) *Alkaline iodide soln.*—Prep. as in 33.028(a), except omit  $\text{NaN}_3$ .

(b) *Potassium oxalate soln.*—2%. Dissolve 2 g  $\text{K}_2\text{C}_2\text{O}_4 \cdot \text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ . 1 mL equiv. to 1.1 mL  $\text{KMnO}_4$  soln, (c).

(c) *Potassium permanganate soln.*—6.3 g/L.

#### 33.031

#### Determination

Add to sample 0.70 mL  $\text{H}_2\text{SO}_4$  and then 1.0 mL  $\text{KMnO}_4$  soln. If sample is high in Fe, also add 1.0 mL KF soln, 33.028(d). If necessary, add addnl  $\text{KMnO}_4$  soln to maintain violet tinge 5 min. (If  $>5$  mL is required, prep. stronger  $\text{KMnO}_4$  soln to avoid diln of sample.) After 5 min, decolorize with just enough oxalate soln (usually 0.5–1.0 mL) within 2–10 min. Add 2.0 mL  $\text{MnSO}_4$  soln, 33.028(b), and 3.0 mL alk.  $\text{I}_2$  soln, 33.030(a). Stopper bottle and mix. Let ppt settle, remix 20 sec, and let settle until  $\geq 100$  mL clear supernate is present. Acidify with 2.0 mL  $\text{H}_2\text{SO}_4$ . Titr., using vol. of 205 mL, and calc. as in 33.029.

#### Method III, Pomeroy-Kirshman-Alsterberg Method

#### 33.032

#### Reagent

*Alkaline iodide-sodium azide soln.*—Dissolve 400 g NaOH in 500 mL freshly boiled and cooled  $\text{H}_2\text{O}$ . Cool slightly and then add 900 g NaI; mix. Dissolve 10 g  $\text{NaN}_3$  in 40 mL  $\text{H}_2\text{O}$ . Add slowly, with stirring, to alk.  $\text{I}_2$  soln, bringing total vol. to  $\geq 1$  L.

#### 33.033

#### Determination

To sample add 2.0 mL  $\text{MnSO}_4$  soln, 33.028(b), and 2.0 mL alk.  $\text{I}_2$ - $\text{NaN}_3$  soln, 33.032. Stopper and mix by inversion. After ppt has settled, add 2.0 mL  $\text{H}_2\text{SO}_4$  and mix. Titr., using vol. of 203 mL, and calc. as in 33.029.

#### Chemical Oxygen Demand (COD) (1, 3)

#### 33.034

#### Principle

Org. substances are oxidized by  $\text{K}_2\text{Cr}_2\text{O}_7$  in  $\text{H}_2\text{SO}_4$  (1+1) at reflux temp. with  $\text{Ag}_2\text{SO}_4$  as catalyst and  $\text{HgSO}_4$  to remove Cl interference. Excess dichromate is titrd with  $\text{Fe}^{+2}$ , using ortho-phenanthroline as indicator. Method is independent detn of org. matter in sample and has no definable relationship to biological oxygen demand (BOD).

Method is applicable to surface and saline waters and industrial wastes. Apply Method I, using 0.25N reagents, to samples contg  $>50$  mg COD/L; apply low level modification, Method II, using 0.025N reagents, to samples in range 5–50 mg/L; apply special modification, Method III, to saline waters contg  $>1000$  mg Cl/L and  $>250$  mg COD/L.

Org. matter from glassware, atm., and distd  $\text{H}_2\text{O}$  must be excluded. Condition glassware by using it for blank detn to eliminate org. matter.

Distd  $\text{H}_2\text{O}$  contg known increments of oxidizable org. material analyzed by 89 analysts in 58 laboratories showed following results:

Increment org. material, mg/L	Std deviation		Bias	
	%	mg/L	%	mg/L
12.3	34	4	0	0
270	7	18	-2	-5

#### 33.035

#### Preparation of Sample

Collect samples in glass bottles if possible; plastic may be used if it contributes no org. material to sample. Test biologically active samples as soon as possible. Mix or homogenize samples contg settleable materials. Samples may be preserved with  $\text{H}_2\text{SO}_4$ , 2 mL/L.

**33.036****Apparatus and Reagents**

(a) *Reflux apparatus*.—500 mL erlenmeyer or 300 mL r-b flask with 3 joint connected to 30 cm (12") Allihn condenser.

(b) *Distilled water*.—Low in org. matter. Ordinary distd H<sub>2</sub>O is satisfactory; do not use deionized H<sub>2</sub>O.

(c) *Potassium dichromate std solns*.—(1) 0.25*N*.—Dissolve 12.259 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, primary std grade, previously dried 2 hr at 103°, in distd H<sub>2</sub>O and dil. to 1 L. (2) 0.025*N*.—Dil. 100 mL 0.25*N* to 1 L with H<sub>2</sub>O.

(d) *Sulfuric acid reagent*.—Dissolve 23.5 g Ag<sub>2</sub>SO<sub>4</sub> in 9 lb (4.1 kg) bottle H<sub>2</sub>SO<sub>4</sub>. (1–2 days may be required for dissoln.)

(e) *Ferrous ammonium sulfate std soln*.—(1) 0.25*N*.—Dissolve 98 g Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>·6H<sub>2</sub>O in H<sub>2</sub>O, add 20 mL H<sub>2</sub>SO<sub>4</sub>, cool, and dil. to 1 L. Stdze daily against 0.25*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, (c)(1). (2) 0.025*N*.—Dil. 100 mL 0.25*N* to 1 L with H<sub>2</sub>O. Stdze daily against 0.025*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, (c)(2).

(f) *Phenanthroline ferrous sulfate (ferroin) indicator soln*.—Dissolve 1.48 g 1,10-(ortho)-phenanthroline·H<sub>2</sub>O and 0.70 g FeSO<sub>4</sub>·7H<sub>2</sub>O in 100 mL H<sub>2</sub>O.

**33.037****Standardization of Ferrous Solutions**

(a) *Concentrated soln*.—Dil. 25.0 mL 0.25*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, (c)(1), to ca 250 mL with H<sub>2</sub>O. Add 75 mL H<sub>2</sub>SO<sub>4</sub> and cool. Titr. with 0.25*N* Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>, using 10 drops ferroin indicator. Normality = (mL K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> × normality)/mL Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>.

(b) *Dilute soln*.—To 15 mL H<sub>2</sub>O add 10.0 mL 0.025*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, (c)(2). Add 20 mL H<sub>2</sub>SO<sub>4</sub> and cool. Titr. with 0.025*N* Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>, using 1 drop ferroin indicator. Blue-green to reddish brown color change is sharp. Calc. normality as in (a).

**33.038 Method I—High Level**

(Caution: See 51.065 and 51.079.)

Place several boiling chips and 1 g HgSO<sub>4</sub> in reflux flask. Add 5.0 mL H<sub>2</sub>SO<sub>4</sub> and swirl until HgSO<sub>4</sub> dissolves. Place in ice bath and slowly add, with swirling, 25.0 mL 0.25*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>. Slowly, and with swirling, add 70.0 mL H<sub>2</sub>SO<sub>4</sub>-Ag<sub>2</sub>SO<sub>4</sub> reagent. While still in bath, pipet in 50 mL sample (or aliquot dild to 50 mL) with continuous mixing. Attach condenser and reflux 2 hr. (Shorter period may be used on waste H<sub>2</sub>O of const or known composition where time of max. oxidn has been detd previously.)

Cool, and wash down condenser with ca 25 mL H<sub>2</sub>O. If r-b flask has been used, quant. transfer soln to 500 mL erlenmeyer. Dil. to ca 300 mL with H<sub>2</sub>O, and let cool to ca room temp. Add 8–10 drops ferroin indicator, and titr. excess K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> with 0.25*N* Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub> to sharp, reddish end point (*S* mL). Perform blank detn with all reagents, including refluxing, on distd H<sub>2</sub>O in place of sample and det. mL 0.25*N* Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub> required (*B* mL).

$$\text{mg COD/L} = (B - S) \times N \times 8000/V,$$

where *N* = normality Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub> soln and *V* = vol. sample used.

**33.039 Method II—Low Level**

Proceed as in high level detn, 33.038, except use 0.025*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub>.

**33.040 Method III—Saline Waters**

Pipet 50 mL sample of 250–800 mg COD/L and Cl<sup>−</sup> >1000 mg/L (or aliquot dild to 50 mL with distd H<sub>2</sub>O having Cl<sup>−</sup> concn equal to that of sample) into 500 mL erlenmeyer and add 25.0 mL 0.25*N* K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and 5.0 mL H<sub>2</sub>SO<sub>4</sub>. Add 10 mg HgSO<sub>4</sub>/mg Cl in sample and swirl until dissolved. Carefully add 70.0 mL H<sub>2</sub>SO<sub>4</sub>-Ag<sub>2</sub>SO<sub>4</sub> reagent with swirling. Add several boiling chips, attach condenser, and reflux 2 hr. (If volatile org. compds are present

in sample, attach condenser prior to addn of H<sub>2</sub>SO<sub>4</sub>-Ag<sub>2</sub>SO<sub>4</sub> reagent and add reagent thru condenser while cooling flask in ice bath.)

Cool, and proceed as in low level detn, 33.039, including blank. Disregard reappearance of blue-green after end point is reached.

For saline waters, prep. std curve of COD against mg Cl<sup>−</sup>/L, using NaCl solns with intervals of ≤4000 up to 20,000 mg Cl<sup>−</sup>/L, carried thru entire detn.

$$\text{COD, mg/L} = [(B - S) \times N \times 8000 - 50D] \times 1.20/V,$$

where *D* = Cl<sup>−</sup> correction from std curve, and 1.20 is compensation factor to account for extent of Cl<sup>−</sup> oxidn which is dissimilar in org. and inorg. systems. Other symbols are defined in 33.038.

**33.041 Total Solids—Official Final Action**

Thoroughly shake sample, and pipet 100 mL unfiltered sample into weighed Pt dish. If sample contains much suspended matter, shake, pour rapidly into 100 mL graduate, and immediately transfer to weighed Pt dish. Evap. to dryness and heat to const wt at 100°.

**33.042 Solids in Solution—Official Final Action**

Let sample stand until all sediment settles and filter if necessary to secure perfectly clear liq. (Occasionally, clear filtrate can be obtained only by use of alumina cream, 31.021(b); avoid if possible.) Evap. 100–250 mL to dryness in weighed Pt dish. Heat to const wt at 100°.

**33.043 Ignited Residue—Official Final Action**

Ignite residue from 33.041 at 525–550° in furnace or over burner until dish shows dull red glow and ash is white or nearly so. Note any odor or change in color produced during ignition. Det. wt ignited residue and calc. loss on ignition.

**Organic Carbon (1, 3)****33.044****Principle**

Carbonaceous material of water sample is oxidized to CO<sub>2</sub> in stream of O or air in catalytic combustion tube at 950°. Calibrated IR analyzer measures CO<sub>2</sub>.

Method is applicable to 1–150 mg org. C in surface and saline waters and domestic and industrial wastes. Preliminary treatment of sample defines type of C measured: (1) sol., nonvolatile org. C (e.g., natural sugars); (2) sol., volatile org. C (e.g., mercaptans); (3) insol., partially volatile C (e.g., oils); (4) insol., particulate carbonaceous materials (e.g., cellulose fibers); (5) sol. or insol. carbonaceous materials adsorbed or entrapped on insol. inorg. suspended matter (e.g., oily matter adsorbed on silt particles).

Since usefulness of method is in assessing potential O-demanding load of org. material, CO<sub>3</sub> and HCO<sub>3</sub> carbon must be removed before analysis or subtracted from final result.

Distd H<sub>2</sub>O analyzed by 28 analysts in 21 laboratories showed following results on exact increments of oxidizable org. compds:

Added total org. C, mg/L	Std deviation		Bias	
	%	mg/L	%	mg/L
4.9	80	3.9	+15	0.75
107	8	8.3	+1	1.1

**33.045****Preparation of Sample**

Glass bottles are preferable storage containers but polyethylene and Cubitainers (Hedwin Corp., 1209 E Lincoln Way, La

Port, IN 46390) may be used if tests show no contribution of C to samples. Keep interval between collection and analysis at min., store at 4°, and protect from light and O. If samples cannot be analyzed within 2 hr, acidify to pH <2 with HCl or H<sub>2</sub>SO<sub>4</sub>.

**33.046****Apparatus**

(a) *Organic carbon analyzer*.—Dow-Beckman Carbonaceous Analyzer (single channel) or Model No. 915 (dual channel) (Beckman Instruments), or equiv., with air pump, purification train, flow controls, nondispersive-type IR stream analyzer specific for CO<sub>2</sub>, and recorder.

(b) *Syringes*.—(1) 0–50 µL, needle opening ca 150 µm, Hamilton No. 705N, or equiv.; (2) 0–500 µL, needle opening ca 400 µm, for samples with large particulates, Hamilton No. 750N, or equiv.; or (3) push button syringes which ensure uniformity of injection rate, 20 or 200 µL size, Hamilton No. CR700-20 or CR700-200, or equiv.

**33.047****Reagents**

(Caution: See 51.086.)

(a) *Water*.—For diln of samples and prepn of stds, blanks, and reagents. Use CO<sub>2</sub>-free, double distd H<sub>2</sub>O; do not use H<sub>2</sub>O purified by ion exchange.

(b) *Organic carbon std solns*.—(1) *Stock phthalate soln*.—1000 mg C/L. Dissolve 0.2128 g KH phthalate, 50.033(c), in H<sub>2</sub>O, and dil. to 100 mL. (2) *Working solns*.—Prep. solns contg 10, 20, 30, 40, 50, 60, 80, and 100 mg C/L by dilg 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 8.0, and 10.0 mL stock soln to 100 mL with H<sub>2</sub>O.

(c) *Carbonate carbon std solns*.—(1) *Stock soln*.—1000 mg C/L. Dissolve 0.3500 g NaHCO<sub>3</sub> and 0.4418 g Na<sub>2</sub>CO<sub>3</sub> in H<sub>2</sub>O and dil. to 100 mL. (2) *Working solns*.—Prep. identical series with concns as in (b)(2).

(d) *Packing for total carbon tube*.—Dissolve 20 g Co(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O in 50 mL H<sub>2</sub>O and add to 15 g long fiber asbestos in porcelain evapg dish. Mix, and evap. to dryness on steam bath. Place in cold furnace, heat to 950°, and hold at this temp. 1–2 hr. Cool, break up any lumps, and mix adequately but not excessively. With combustion tube held vertically, taper joint up, add ca 1 cm untreated asbestos and then ca 1 g catalyst transferred in small amts with forceps. As it is added, tap or push material with 6 mm glass rod, using only wt of rod to compress material. Do not force packing. When completed, length of packing should be ca 5–6 cm. Test packed tube by measuring flow rate of gas thru it at room temp. and at 950°. Rate should drop <20%.

(e) *Packing for carbonate tube (dual channel instrument)*.—Place small wad of quartz wool or asbestos near exit of carbonate evolution tube. From entrance end add 6–12 mesh quartz chips to length of 10 cm. Add H<sub>3</sub>PO<sub>4</sub> while holding tube vertically and let excess drain.

**33.048****Adjustment of Instrument**

Turn on IR analyzer, recorder, and furnaces, setting total C furnace at 950° and carbonate furnace at 175°. Let warm up >2 hr; leave on continuously for daily operation. Adjust O flow to 80–100 mL/min thru total C tube. With recorder set at appropriate mv range, adjust amplifier gain so that 20 µL sample of 100 mg C/L std gives peak ht ca half scale. Noise level should be <0.5% full scale; if higher, analyzer or recorder may need servicing.

If single channel unit is equipped with large diam. combustion tube and dual channel unit with Hastalloy tube for total C channel, use 100 µL sample in range 1–30 mg C/L.

**33.049****Calibration**

(a) *Dual channel instrument*.—Rinse syringe several times with std soln, fill, and adjust to 20 µL. Wipe off excess with soft paper tissue, taking care that no lint adheres to needle. Remove plug from syringe holder, insert syringe, and inject soln into tube with single, rapid movement of index finger. Leave syringe in holder until flow rate returns to normal; then replace it with plug. Run duplicate detns on each std soln and on blank. Read ht of each peak. Let recorder return to baseline between injections. Subtract blank from each peak and prep. std curve of corrected peak ht against mg C/L.

Turn 4-way valve to direct flow thru low temp. tube and analyzer. Adjust flow to 80–100 mL/min and let baseline stabilize. Inject in duplicate 20 µL each of 20, 40, 60, 80, and 100 mg inorg. C/L std solns and blank. Prep. std curve of corrected peak ht against mg inorg. C/L.

(b) *Single channel instrument*.—Prep. std curve as in (a), par. 1.

**33.050****Determination**

(a) *Dual channel instrument*.—Mix sample thoroly and dil. to bring C content within range of std curve. Inject 20 µL sample in duplicate as in 33.049(a) and det. peak hts corresponding to total and inorg. C. Convert to concn and subtract inorg. C from total C to obtain total org. C. Results may be verified by operating unit as single channel system, injecting acidified, N-purged sample into high temp. furnace, and comparing results.

Filter 100 mL aliquot sample thru prerinsed 0.45 µm fritted glass filter and repeat detn to obtain dissolved C values. Subtract dissolved or inorg. C to obtain dissolved org. C. Results may be verified by operating unit as single channel system, injecting acidified, N-purged, filtered sample into high temp. furnace, and comparing results.

(b) *Single channel instrument*.—Transfer 10–15 mL sample to 30 mL beaker. If sample is not acid-preserved, add 2 drops HCl to reduce pH to ≤2 and purge with CO<sub>2</sub>-free N ca 5–10 min. (Do not use plastic tubing.) Place beaker on mag. stirrer and withdraw 20 µL aliquot while stirring. Inject as in 33.049(a). Prep. and inject filtered samples. Calc. total, inorg., and dissolved C as in (a).

**Total Nitrogen—Kjeldahl Method (1, 4)****33.051****Principle**

Sample is digested with H<sub>2</sub>SO<sub>4</sub> to convert org. N to NH<sub>3</sub>, which is distd after alkalization and detd by nesslerization or titrimetry. Preserve samples by addn of 40 mg HgCl<sub>2</sub>/L and store at 4°. Analyze as soon as possible, as conversion of org. N to NH<sub>3</sub> may occur even with preservation.

Method is applicable to surface and saline waters and domestic and industrial wastes. Some industrial wastes contg materials such as amines, nitro compds, hydrazones, oximes, semicarbazones, and some refractory tertiary amines may not be converted to NH<sub>3</sub>.

Natural H<sub>2</sub>O analyzed by 31 analysts in 20 laboratories showed the following results on exact increments of org. N:

Method	Added, mg N/L	Std deviation		Bias	
		%	mg N/L	%	mg N/L
Colorm.	0.20	100	0.20	+15.5	0.03
Colorm.	0.31	81	0.25	+5.5	0.02
Tit.	4.10	26	1.06	+1.0	0.04
Tit.	4.61	26	1.19	–1.7	–0.08

## 33.052

## Apparatus

(a) *Digestion apparatus*.—See 2.056(a).

(b) *Distillation apparatus*.—See 2.056(b); or use all-glass app. with 800 or 1000 mL distg flask and 500 mL g-s erlenmeyers, marked at 350 and 500 mL, as receivers. Prep. for use by distg mix. of NaOH-Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln and H<sub>2</sub>O (1+1) until distillate is NH<sub>3</sub>-free by Nessler reagent, (j). Repeat each time app. is out of service  $\geq 4$  hr.

(c) *Nessler tubes*.—Matched, ca 300 mm long, 17 mm id, and marked at 225  $\pm$  1.5 mm inside measurement from bottom.

(d) *Spectrophotometer or filter photometer*.—For use at 425 nm.

## 33.053

## Reagents

(Caution: See 51.065, 51.079, and 51.084.)

(a) *Water*.—Distd, NH<sub>3</sub>-free. Pass thru ion exchange column of mixed strongly acidic cation and strongly basic anion exchange resins. Regenerate resins according to manufacturer's instructions.

(b) *Mercuric sulfate soln*.—Dissolve 8 g red HgO in 50 mL H<sub>2</sub>SO<sub>4</sub> (1+5) and dil. to 100 mL with H<sub>2</sub>O.

(c) *Digestion soln*.—Dissolve 267 g K<sub>2</sub>SO<sub>4</sub> in 1300 mL H<sub>2</sub>O and add 400 mL H<sub>2</sub>SO<sub>4</sub>. Add 50 mL HgSO<sub>4</sub> soln, (b), and dil. to 2 L.

(d) *Sodium hydroxide-sodium thiosulfate soln*.—Dissolve 500 g NaOH and 25 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L.

(e) *Phenolphthalein indicator soln*.—Dissolve 5 g phthln in 500 mL alcohol or isopropanol and add 500 mL H<sub>2</sub>O. Add 0.02N NaOH until faint pink.

(f) *Sulfuric acid std soln*.—0.02N. Prep. and stdze as in 50.039–50.041. 1.00 mL = 0.28 mg N.

(g) *Ammonia std solns*.—(1) *Stock soln*.—1.00 mg N/mL. Dissolve 3.819 g NH<sub>4</sub>Cl in H<sub>2</sub>O and dil. to 1 L. (2) *Working soln*.—0.01 mg N/mL. Dil. 10 mL stock soln to 1 L.

(h) *Boric acid soln*.—Dissolve 20 g H<sub>3</sub>BO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L.

(i) *Mixed indicator*.—Mix 2 vols 0.2% alc. Me red with 1 vol. 0.2% alc. methylene blue. Prep. fresh every 30 days. SDA 3-A or 30 denatured alcohol may be used.

(j) *Nessler reagent*.—Dissolve 100 g HgI<sub>2</sub> and 70 g KI in small amt H<sub>2</sub>O. Add slowly, with stirring, to cooled soln of 160 g NaOH in 500 mL H<sub>2</sub>O, and dil. to 1 L. Reagent is stable 1 year if stored in Pyrex container out of direct sunlight. Reagent should give characteristic color, but no ppt, with 0.04 mg NH<sub>3</sub>-N in 50 mL H<sub>2</sub>O within 10 min.

## 33.054

## Digestion and Distillation

Det. sample size as follows:

mg N/L	mL sample
0–5	500
5–10	250
10–20	100
20–50	50.0
50–100	25.0

Place sample, or residue from NH<sub>3</sub> detn (for org. Kjeldahl N only), into 800 mL Kjeldahl flask. Dil., if necessary, to 500 mL and add 100 mL digestion soln, (c). Boil until SO<sub>3</sub> fumes are evolved and soln becomes colorless or pale yellow. Cool, and dil. with 300 mL H<sub>2</sub>O. Add NaOH-Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln slowly down neck of tilted flask to underlay acid soln in amt sufficient to make final soln strongly alk. as shown by phthln (60 mL NaOH-Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln will neutze 20 mL H<sub>2</sub>SO<sub>4</sub>). Connect flask to condenser, with tip of condenser dipping into 50 mL 2% H<sub>3</sub>BO<sub>3</sub> soln in 500 mL g-s erlenmeyer. If soln is to be titrd, 100 or 200 mL H<sub>3</sub>BO<sub>3</sub> may be used. Mix solns and distil 300 mL at 6–10 mL/min. If NH<sub>3</sub>

concn is  $\geq 1$  mg/L, det. titrimetrically, 33.055; if less, det. colorimetrically, 33.056.

## 33.055

## Titrimetric Determination

Add 3 drops mixed indicator, (i), to distillate and titr. with 0.02N H<sub>2</sub>SO<sub>4</sub>, (f), matching end point against blank contg same vol. NH<sub>3</sub>-free H<sub>2</sub>O, H<sub>3</sub>BO<sub>3</sub> soln, and indicator.

mg Total N/L = [(mL std H<sub>2</sub>SO<sub>4</sub> for sample – mL std H<sub>2</sub>SO<sub>4</sub> for reagent blank)  $\times$  normality std H<sub>2</sub>SO<sub>4</sub>  $\times$  14.01  $\times$  1000]/mL sample digested.

## 33.056

## Colorimetric Determination

Prep. series of stds contg 0.0, 0.2, 0.5, 1.0, 1.5, 2.0, 3.0, and 4.0 mL NH<sub>3</sub> working std soln, (g)(2), dild to 50 mL with NH<sub>3</sub>-free H<sub>2</sub>O (contains 0.0, 0.04, 0.10, 0.20, 0.30, 0.40, 0.60, and 0.80 mg NH<sub>3</sub> N/L). Add 1 mL Nessler reagent, (j), and mix. After 20 min, read *A* at 425 nm against 0.0 (blank) std, and plot *A* against concn to obtain std curve. Distil 1 or more high and low std solns daily to ensure adequate recoveries.

As estd by preliminary detn, det. NH<sub>3</sub> in 50 mL aliquot, or aliquot dild to 50 mL, as above, and read NH<sub>3</sub> concn from std curve.

mg Total N/L = [(mg NH<sub>3</sub>-N from curve  $\times$  1000)/mL sample taken for distn]  $\times$  (mL final distillate, including H<sub>3</sub>BO<sub>3</sub> soln/mL distillate taken for nesslerization).

## Ammonia Nitrogen (1, 4)

## 33.057

## Principle

Sample buffered at pH 9.5 is distd into H<sub>3</sub>BO<sub>3</sub> soln. Depending upon concn, NH<sub>3</sub> is detd colorimetrically (0.05–1.0 mg N/L) by nesslerization or titrimetry (1.0–25 mg N/L). Hg, if present as preservative, and residual Cl must be removed by addn of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> before distn.

Method is applicable to surface and saline waters and domestic and industrial wastes. A number of volatile amines will cause turbidity with Nessler reagent. Some volatile compds, such as certain ketones, aldehydes, and alcohols, may cause off color on nesslerization. Some of these, such as HCHO, may be eliminated by boiling at pH 2–3 before distn. Volatile compds, such as hydrazine, influence titrimetric results.

Natural and distd H<sub>2</sub>O analyzed by 24 analysts in 16 laboratories showed the following results on exact increments of ammonium salt:

Method	Type	Added, mg N/L	Std deviation		Bias	
			%	mg N/L	%	mg N/L
Colorm.	Distd.	0.21	58	0.122	–5.54	–0.01
Colorm.	Nat.	0.26	27	0.070	–18.12	–0.05
Titrim.	Distd.	1.71	14	0.244	+0.46	+0.01
Titrim.	Nat.	1.92	15	0.279	–2.01	–0.04

## 33.058

## Apparatus

See 33.052(b), (c), and (d).

## 33.059

## Reagents

See 33.053(a), (f)–(j), and following:

(a) *Borate buffer*.—pH 9.5. Add 88 mL 0.1N NaOH to 500 mL 0.025M Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> (5.0 g anhyd. salt/L), and dil. to 1 L.

(b) *Sodium hydroxide soln*.—1N. Dissolve 40 g NaOH in NH<sub>3</sub>-free H<sub>2</sub>O and dil. to 1 L.

(c) *Dechlorinating reagent*.—Dissolve 3.5 g Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> in NH<sub>3</sub>-free H<sub>2</sub>O and dil. to 1 L. 1 mL will remove 0.5 mg residual Cl in 500 mL sample.

**33.060****Distillation**

Add 500 mL  $\text{NH}_3$ -free  $\text{H}_2\text{O}$  and few boiling chips previously treated with  $\text{NaOH}$  soln to Kjeldahl distg flask.

Adjust 400 mL sample to pH 9.5 with 1N  $\text{NaOH}$ , using pH meter or short range test paper. If sample contains residual  $\text{Cl}$ , remove by adding equiv. amt dechlorinating reagent, (c). Transfer to distg flask and add 25 mL buffer, (a). Distil 300 mL at 6–10 mL/min into 50 mL  $\text{H}_3\text{BO}_3$  soln, **33.053(h)**. Dil. distillate to 500 mL in receiving flask. Det.  $\text{NH}_3$  in 50 mL aliquot as in colorimetric detn. If  $\text{NH}_3$  concn is  $\geq 1$  mg/L, det. titrimetrically, **33.061**; if less, det. colorimetrically, **33.062**.

**33.061****Titrimetric Determination**

Proceed as in **33.055**, using remaining 450 mL distillate.

$\text{mg NH}_3\text{-N/L} = (\text{mL } 0.02\text{N H}_2\text{SO}_4 \times 1000)/\text{equiv. mL sample in aliquot titrd.}$

**33.062****Colorimetric Determination**

Proceed as in **33.056**.

$\text{mg NH}_3\text{-N/L} = (\text{NH}_3 \text{ concn from std curve} \times 1000)/(0.8 \times \text{mL distillate taken for detn.})$

**Nitrate Nitrogen (1, 4)****Brucine Colorimetric Method****33.063****Principle**

Nitrate ion reacts with brucine in  $\text{H}_2\text{SO}_4$  at  $100^\circ$  to form colored compd whose  $A$  is measured at 410 nm. Temp. control of reaction is critical. Applicable to 0.1–2 mg  $\text{NO}_3\text{-N/L}$  in surface and saline waters and domestic and industrial wastes.

Org. matter developing color with  $\text{H}_2\text{SO}_4$  and natural color are compensated for by blank; effect of salinity is compensated for by addn of  $\text{NaCl}$ . Strong oxidizing and reducing agents interfere. Det. presence of free  $\text{Cl}$  with  $o$ -tolidine reagent. Eliminate residual  $\text{Cl}$  by addn of  $\text{NaAsO}_3$  soln. Effect of  $\text{Fe}^{+2}$ ,  $\text{Fe}^{+3}$ , and  $\text{Mn}^{+4}$  is negligible at  $<1$  mg/L.

Natural  $\text{H}_2\text{O}$  analyzed by 27 analysts in 15 laboratories showed the following results on exact increments of inorg. nitrate:

Added, mg N/L	Std deviation		Bias	
	%	mg N/L	%	mg N/L
0.16	58	0.092	-6.8	-0.01
0.19	44	0.083	+8.3	+0.02
1.08	23	0.245	+4.1	+0.04
1.24	17	0.214	+2.8	+0.04

**33.064****Apparatus**

(a) *Spectrophotometer or filter photometer.*—Capable of accommodating 25 mm diam. tubes and measuring  $A$  at 410 nm.

(b) *Tubes.*—Matched tubes for conducting reaction and measuring  $A$ .

(c) *Racks.*—Neoprene, wire coated, evenly spaced, to permit uniform flow of bath  $\text{H}_2\text{O}$  between tubes.

(d) *Water baths.*—(1)  $100^\circ$ .—Boiling  $\text{H}_2\text{O}$  bath of sufficient size so that when tubes are inserted, temp. drop is  $\leq 1-2^\circ$ . Should have tight-fit cover, preferably of gable construction, with circulator or stirrer to maintain uniform temp. *Uniform temp. control of this bath is critical.* (Caution: Check  $\text{H}_2\text{O}$  bath to assure it is electrically grounded.) (2)  $10-15^\circ$ .—For cooling tubes.

**33.065****Reagents**

(a) *Water.*—Use distd or deionized  $\text{H}_2\text{O}$  for prepn of all reagents and stds.

(b) *Salt soln.*—Dissolve 300 g  $\text{NaCl}$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) *Sulfuric acid.*—13N. Carefully add 500 mL  $\text{H}_2\text{SO}_4$  to 125 mL  $\text{H}_2\text{O}$ . Cool, and keep tightly stoppered.

(d) *Brucine-sulfanilic acid reagent.*—Dissolve 1 g brucine sulfate.  $7\text{H}_2\text{O}$  and 0.1 g sulfanilic acid.  $\text{H}_2\text{O}$  in 70 mL  $\text{H}_2\text{O}$ . Stored in dark bottle at  $5^\circ$ , soln is stable several months. Slowly developing pink does not affect usefulness.

(e) *Nitrate std solns.*—(1) *Stock soln.*—100 mg N/L. Dissolve 0.7218 g  $\text{KNO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L. (2) *Working soln.*—1 mg/L. Dil. 10 mL stock soln to 1 L. Prep. fresh weekly.

**33.066****Determination**

(Caution: See **51.018** and **51.030**.)

Preserve samples with 40 mg  $\text{HgCl}_2/\text{L}$  and store at  $4^\circ$ . Adjust pH to ca 7 with  $\text{HOAc}$  (1+3) and, if necessary, filter thru  $0.45 \mu\text{m}$  filter.

Prep. set of matched tubes for blanks, stds, and samples. If necessary to correct for color or for org. matter which will cause color on heating, add extra set of tubes to which all reagents except brucine will be added.

Pipet 10 mL sample, or aliquot dild to 10 mL, into sample tubes. For saline sample, add 2.0 mL 30%  $\text{NaCl}$  soln to samples, stds, and blank tubes. Swirl tubes and place in  $0-10^\circ$  bath. Pipet 10 mL 13N  $\text{H}_2\text{SO}_4$  into each tube and swirl. Let all tubes come to thermal equilibrium. Pipet 0.5 mL brucine reagent to all tubes except color control tubes and swirl. Then place entire rack contg all tubes in boiling  $\text{H}_2\text{O}$  bath for exactly 25 min. Remove rack and transfer to cold  $\text{H}_2\text{O}$  bath and let cool to  $20-25^\circ$ . Dry tubes and read  $A$  against reagent blank at 410 nm.

Prep. set of stds contg 0.1–2 mg N/L and conduct stds along with samples. Color may not follow Beer's law. If necessary, subtract  $A$  of color controls from  $A$  of samples.

**Chloride (1, 2)****Mercuric Nitrate Method****33.067****Principle**

Chloride titrd with mercuric ions forms sol., slightly dissociated  $\text{HgCl}_2$ . In pH range 2.3–2.8, diphenylcarbazone indicates end point by forming purple complex with excess  $\text{Hg}^{+2}$ . Xylene cyanol FF serves as pH indicator and background color to facilitate end point detection.  $\text{NaHCO}_3$  added to both blank and sample followed by const amt of  $\text{HNO}_3$  added with indicators provides pH of  $2.5 \pm 0.1$ . Increasing strength of titrant and modifying indicator mixt. permits detn of high  $\text{Cl}$  concns common in waste water.

$\text{Br}$  and  $\text{I}$  titr. as chloride. Chromate,  $\text{Fe}^{+3}$ , and  $\text{SO}_3^{-2}$  interfere when present at  $>10$  mg/L. Sulfites may be removed with 0.5–1 mL  $\text{H}_2\text{O}_2/50$  mL sample. Methods are applicable to drinking, surface, and saline waters, and domestic and industrial wastes at all  $\text{Cl}$  concns. However, to avoid large titrn vols, use sample contg  $<20$  mg  $\text{Cl}/50$  mL.

Synthetic  $\text{H}_2\text{O}$  samples analyzed by 42 analysts in 18 laboratories showed the following results on exact increments of  $\text{Cl}$ :

Added, mg Cl/L	Std deviation		Bias	
	%	mg Cl/L	%	mg Cl/L
17	9.1	1.54	+2.2	+0.4
18	7.3	1.32	+3.5	+0.6
91	3.2	2.92	+0.1	+0.1
97	3.3	3.16	-0.5	-0.5
382	3.1	11.7	-0.6	-2.3
398	3.0	11.8	-1.2	-4.7

**33.068****Reagents**

(a) *Sodium chloride std soln.*—0.0141*N*. Dissolve 824.1 mg NaCl, dried at 140°, in Cl-free H<sub>2</sub>O, and dil. to 1 L. 1 mL = 0.500 mg Cl.

(b) *Chlorine-free water.*—Redistd or deionized.

*For Low Chloride Concentration*

(c) *Indicator-acidifier reagent.*—(Neutzes 150 mg CaCO<sub>3</sub>/L in 100 mL sample.) Dissolve, in order given, 250 mg *s*-diphenylcarbazone, 4.0 mL HNO<sub>3</sub>, and 30 mg xylene cyanol FF in 100 mL alcohol or isopropanol. Store in dark bottle in refrigerator. For routine analysis of samples with very high or low alky, HNO<sub>3</sub> concn may be adjusted so that final pH when added to samples is 2.5±0.1.

(d) *Mercuric nitrate std soln.*—0.0141*N*. Dissolve 2.3 g Hg(NO<sub>3</sub>)<sub>2</sub> or 2.5 g Hg(NO<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>O in 100 mL H<sub>2</sub>O contg 0.25 mL HNO<sub>3</sub>. Dil. to just under 1 L. Stdze as in 33.069(a), using 5.00 mL aliquot NaCl std soln, (a), and 10 mg NaHCO<sub>3</sub>, dild to 100 mL. Adjust soln to exactly 0.0141*N* and perform final stdzn. Store in dark bottle away from light. 1 mL = 0.500 mg Cl.

*For High Chloride Concentration*

(e) *Mixed indicator.*—Dissolve 5 g *s*-diphenylcarbazone and 0.5 g bromophenol blue in 750 mL alcohol or isopropanol and dil. to 1 L with same solv.

(f) *Mercuric nitrate std soln.*—0.141*N*. Dissolve 25 g Hg(NO<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>O in 900 mL H<sub>2</sub>O contg 5.0 mL HNO<sub>3</sub>. Dil. to just under 1 L. Stdze as in 33.069(b), using 25.00 mL aliquots NaCl std soln, (a), and 25 mL H<sub>2</sub>O. Adjust soln to exactly 0.141*N* and perform final stdzn. Store in dark bottle away from light. 1 mL = 5.00 mg Cl.

**33.069****Determination**

(a) *For low chloride (drinking water).*—To ≤100 mL sample contg ≤10 mg Cl, add 1.0 mL indicator-acidifier, (c). Color should be green-blue. If not, adjust pH of sample to 8 before addn of reagent. Titr. with 0.0141*N* Hg(NO<sub>3</sub>)<sub>2</sub> to definite purple end point. (Soln becomes blue few drops before end point.) Det. blank by titrn of equal vol. H<sub>2</sub>O contg 10 mg NaHCO<sub>3</sub>.

(b) *For high chloride.*—To 50.0 mL sample (5.00 mL if ≥5 mL titrant needed) in 150 mL beaker, add 0.5 mL mixed indicator, (e), and mix well. Color should be purple. Add 0.1*N* HNO<sub>3</sub> dropwise until just yellow. Titr. with 0.141*N* Hg(NO<sub>3</sub>)<sub>2</sub> to first permanent dark purple. Det. blank by titrn of equal vol. H<sub>2</sub>O.

(c) *Calculation.*—mg Cl/L = [(mL sample titrn - mL blank titrn) × normality Hg(NO<sub>3</sub>)<sub>2</sub> × 35,340]/mL sample.

mg NaCl/L = (mg Cl/L) × 1.65.

**Fluoride (5)—Official Final Action****33.070****Reagents**

(a) *Fluoride std soln.*—0.01 mg F/mL. Dissolve 2.21 g NaF (min. purity 98%) in 1 L H<sub>2</sub>O. Dil. 10 mL of this soln to 1 L.

(b) *Thorium nitrate soln.*—Dissolve 0.25 g Th(NO<sub>3</sub>)<sub>4</sub>·12H<sub>2</sub>O or 0.2 g Th(NO<sub>3</sub>)<sub>4</sub>·4H<sub>2</sub>O in 1 L H<sub>2</sub>O.

(c) *Alizarin red indicator.*—0.01% aq. soln Na alizarin sulfonate (alizarin red S).

(d) *Hydrochloric acid.*—Exactly 0.05*N*.

(e) *Sodium hydroxide soln.*—Exactly 0.05*N*.

(f) *Hydroxylamine hydrochloride soln.*—1.0 g/100 mL.

**33.071****Apparatus**

(a) *Claisen flask.*—250 mL.

(b) *Nessler tubes.*—6 long-form 50 mL tubes with double

optically plane disks fused to tubes. Match tubes for length and test for optical similarity as follows: Add ca 40 mL H<sub>2</sub>O, 1 mL indicator, 2 mL 0.05*N* HCl, and H<sub>2</sub>O to mark on tube. To 1 tube add amt of Th(NO<sub>3</sub>)<sub>4</sub> soln such that, after diltg to mark and mixing, color is barely changed to faint pink. Note amt of Th(NO<sub>3</sub>)<sub>4</sub> soln used. Add same amt of Th(NO<sub>3</sub>)<sub>4</sub> soln to each of remaining 5 tubes. Reject tubes showing detectable differences in shade or intensity.

See also 25.051.

**33.072****Preparation of Sample**

If sample has odor of H<sub>2</sub>S, oxidize with 0.1 mL 30% H<sub>2</sub>O<sub>2</sub> soln before evapn.

Place 100 mL sample in porcelain or Pt dish, make alk. to phthln with 10% NaOH soln (avoid excess), and evap. to 20 mL over burner at temp. just below bp. During evapn keep sample alk. by adding small amts of 0.05*N* NaOH from time to time. Transfer the 20 mL evapd sample to Claisen flask contg glass beads or boiling tube previously rinsed with boiling 10% NaOH soln to eliminate all traces of gelatinous SiO<sub>2</sub> accumulating in flask.

Place flask contg sample on insulating board (15 × 15 × 0.6 cm with 2.5 cm center hole) over burner adjusted for medium flame. Close straight neck of flask with 2-hole rubber stopper thru which pass thermometer and stem of small separator with outlet constricted to 2 mm diam. (Adjust thermometer and outlet tube of separator to extend almost to bottom of flask.) Close other neck of flask with solid rubber stopper. (Alternatively, all-glass distn assembly may be used.)

Connect flask with H<sub>2</sub>O condenser; add 20 mL 60% HClO<sub>4</sub> (Caution: See 51.028(a) and (d)) to flask, rinsing evapg dish and separator; then add amt of satd AgClO<sub>4</sub> soln that will ppt chlorides (detd previously by titrn with std AgNO<sub>3</sub> soln), and distil at 132±3°, adding H<sub>2</sub>O dropwise thru separator to maintain temp. during distn. Collect nearly 200 mL distillate. Dil. to vol. (200 mL) and mix well. To det. acidity, use 40 mL distillate, add 1 mL indicator, mix thoroly, and note mL 0.05*N* NaOH required for neutzn.

Repeat prepn and distn, using 100 mL H<sub>2</sub>O in place of sample, to det. blank.

**33.073****Determination**

Prep. 1 std, 1 color comparison tube, and 1 or more sample tubes as follows:

(a) *Color comparison tube.*—To 40 mL H<sub>2</sub>O add 2 mL 0.05*N* HCl, 1 mL alizarin red indicator, 1 mL NH<sub>2</sub>OH·HCl soln, and enough Th(NO<sub>3</sub>)<sub>4</sub> soln to give faint but definite pink end point. Compare all end point colors with this color.

(b) *Sample tube.*—To sample tube contg 40 mL distillate add 1 mL indicator, 1 mL H<sub>2</sub>NOH·HCl soln, and vol. 0.05*N* HCl such that total vol. acid in tube (acidity previously detd plus vol. 0.05*N* HCl added) equals 2 mL 0.05*N* HCl. Dil. to vol. and mix. If in preliminary acidity detn it is found that the 40 mL distillate requires >2 mL 0.05*N* NaOH soln for neutzn, do not add the HCl soln to sample tube, but add to std tube same amt of acid as was found present in sample tube. If 40 mL distillate requires >5 mL 0.05*N* NaOH, repeat distn under conditions favorable to low acidity. From 10 mL buret, graduated to 0.05 mL, add Th(NO<sub>3</sub>)<sub>4</sub> soln with frequent mixing until faint pink appears, comparable to comparison tube, (a). Note vol. Th(NO<sub>3</sub>)<sub>4</sub> soln used.

(c) *Std tube.*—To std tube contg 40 mL H<sub>2</sub>O add 1 mL indicator, 1 mL H<sub>2</sub>NOH·HCl soln, and ≥2 mL 0.05*N* HCl, as was required in sample tube in (b). If aliquot chosen for detn already contains 2–5 mL 0.05*N* acid, add exactly same amt to std tube. Add

exactly same amt of  $\text{Th}(\text{NO}_3)_4$  soln as was added to sample tube. To std tube (now more highly colored than sample tube), add std F soln from 10 mL buret with mixing until color matches that of sample tube. Dil. contents of both std and sample tubes to same vol. Mix soln in each tube and let all air bubbles escape before making color comparisons. Check end point by adding 1–2 drops std F soln to std tube. Distinct color change should develop.

**33.074****Calculation**

Subtract mL F soln required by blank from mL F soln required by sample.

$$\frac{\text{mL F soln} \times \text{mL total distillate} \times 10}{\text{mL aliquot titrd} \times \text{wt sample taken}} = F \text{ (ppm)}$$

*Example:* 100 mL sample, evapd and distd to 200 mL, of which 40 mL aliquot corresponds to 5 mL F soln, gives:

$$(5 \times 200 \times 10) / (40 \times 100) = 2.5 F \text{ (ppm)}$$

★ **Hydrogen Sulfide (6)—Official Final Action** ★**33.075 Iodometric Method**

See 31.016–31.017, 10th ed.

**33.076 Carbonate and Bicarbonate—Official Final Action**

To 100 mL sample add few drops phthln, and if pink is produced, titr. with 0.05N HCl or  $\text{H}_2\text{SO}_4$ , adding drop every 2–3 sec until color disappears. Multiply buret reading by factor 3 to obtain mg  $\text{CO}_3$  ion in 100 mL. To colorless soln from this titrn, or to original soln if no color is produced with phthln, add 1–2 drops Me orange, continue titrn without refilling buret, and note total reading. If  $\text{CO}_3$  is absent, multiply total buret reading by factor 3.05 to obtain value of  $\text{HCO}_3$  ion in mg/100 mL. If  $\text{CO}_3$  is present, multiply reading with phthln by 2 and subtract from total reading of buret. Multiply difference by 3.05 to obtain  $\text{HCO}_3$  ion in mg/100 mL. Express results as mg/L.

**33.077 Silica—Official Final Action**

Make preliminary examination, using 100–250 mL sample, to det. approx. amt of Ca and Mg present, in order to det. amt of sample to be evapd for final analysis.

Evap. amt of sample equiv. to 0.1–0.6 g CaO or 0.1–1 g  $\text{Mg}_2\text{P}_2\text{O}_7$  (usually 1–5 L). Acidify sample with HCl and evap. on steam bath to dryness in Pt dish. Continue drying ca 1 hr. Thoroughly moisten residue with 5–10 mL HCl. Let stand 10–15 min and add enough  $\text{H}_2\text{O}$  to bring sol. salts into soln. Heat on steam bath until salts dissolve. Filter to remove most of  $\text{SiO}_2$  and wash thoroughly with hot  $\text{H}_2\text{O}$ . Evap. filtrate to dryness and treat residue with 5 mL HCl and enough  $\text{H}_2\text{O}$  to dissolve sol. salts, as before. Heat, filter, and wash thoroughly with hot  $\text{H}_2\text{O}$ . Designate filtrate as *Soln X*.

Transfer the two residues to Pt crucible, ignite, heat over blast lamp, and weigh. Moisten contents of crucible with few drops  $\text{H}_2\text{O}$ , add few drops  $\text{H}_2\text{SO}_4$  and few mL HF, and evap. on steam bath under hood. Repeat treatment if all  $\text{SiO}_2$  is not volatilized. Dry carefully on hot plate, ignite, heat over blast lamp, and weigh. Difference between the two wts is wt  $\text{SiO}_2$ . Add wt residue ( $\text{Fe}_2\text{O}_3 + \text{Al}_2\text{O}_3$ ) to that of  $\text{Al}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$  obtained in 33.078. (If residue weighs >0.5 mg,  $\text{BaSO}_4$  may be present in sample. If so, make necessary correction and add to wt  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$  in 33.078.)

★ Surplus method—see inside front cover.

**33.078 Iron and Aluminum—Official Final Action**

Conc. *Soln X*, 33.077, to 200 mL; while still hot, slowly add  $\text{NH}_4\text{OH}$ , stirring constantly, until alk. to Me orange. Boil, filter, and wash 3 times with hot  $\text{H}_2\text{O}$ . Dissolve ppt in hot HCl (1+1). Dil. to ca 25 mL, boil, and again ppt with  $\text{NH}_4\text{OH}$ . Filter, wash thoroughly with hot  $\text{H}_2\text{O}$ , dry, ignite, and weigh as  $\text{Al}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$ . (In presence of  $\text{H}_3\text{PO}_4$ , wt of this residue must be corrected for  $\text{P}_2\text{O}_5$  equiv. to  $\text{H}_3\text{PO}_4$  found in 33.115, allowing for difference in vols of the water used for these detns.) Designate filtrate as *Soln Y*.

**Iron—Official Final Action****33.079 Colorimetric Method**

(Iron <1 mg; not applicable in presence of phosphates)

Fuse, in Pt crucible, ignited ppt of  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ , 33.078, with fused  $\text{KHSO}_4$ , dissolve in  $\text{H}_2\text{O}$ , and ppt Fe and Al with  $\text{NH}_4\text{OH}$ . Filter, dissolve ppt on filter paper in HCl and  $\text{HNO}_3$ , dil. soln, add 3 mL 5%  $\text{NH}_4\text{SCN}$  soln, dil. to suitable vol., and compare color developed with that of calibrated color disks or stds contg known amts of Fe treated similarly.

**33.080 Volumetric Method**

(Caution: See 51.059.)

Fuse residue of  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ , 33.078, in Pt crucible with ca 1 g fused  $\text{KHSO}_4$ . (Fusion takes only few min, and must not be continued beyond time actually needed.) When fusion is complete, set crucible aside to cool. Add  $\text{H}_2\text{SO}_4$  (1+4) and heat crucible until fused mass dissolves. Evap. on steam bath as far as possible; then heat gradually until copious fumes of  $\text{SO}_3$  evolve. Dissolve in  $\text{H}_2\text{O}$  and let stand on steam bath. Cool, transfer to erlenmeyer, and dil. to such vol. that soln contains  $\leq 2.5\%$  free  $\text{H}_2\text{SO}_4$ .

Pass  $\text{H}_2\text{S}$  thru soln to reduce Fe and ppt any Pt contaminating residue from fusion. (Zn may be used instead of  $\text{H}_2\text{S}$  for reducing Fe.) Filter, wash, and again pass  $\text{H}_2\text{S}$  thru soln to reduce all Fe. Expel  $\text{H}_2\text{S}$  by boiling, at same time passing current of  $\text{CO}_2$  thru soln. Test escaping gas with  $\text{Pb}(\text{OAc})_2$  paper to confirm complete removal of  $\text{H}_2\text{S}$ . Discontinue boiling and let flask cool without discontinuing current of  $\text{CO}_2$ . Titr. reduced Fe with std  $\text{KMnO}_4$  soln (1 mL = 1 mg Fe) and calc. as Fe.

**Hardness (1, 2)****33.081 Calculation Method**

Calc. hardness as sum of  $\text{CaCO}_3$  equivs (mg/L) obtained by multiplying concn (mg/L) found of following cations by factor shown:

Cation	Factor	Cation	Factor
Ca	2.497	Al	5.564
Mg	4.116	Zn	1.531
Sr	1.142	Mn	1.822
Fe	1.792		

**EDTA Titrimetric Method****33.082****Principle**

Ca and Mg at pH 10 in presence of dye eriochrome black T are wine red. When completely complexed with EDTA, soln becomes blue. Mg must be present for satisfactory end point and is added as  $\text{MgEDTA}$ . End point sharpness increases with pH, but high pH may cause pptn of  $\text{Ca}(\text{OH})_2$  or  $\text{Mg}(\text{OH})_2$  and cause color changes of dye. pH of  $10.0 \pm 0.1$  is satisfactory compromise. Limit of 5 min for titrn minimizes pptn. Heavy metal interference is minimized by complexing with cyanide.

Method is applicable to drinking and surface waters and domestic and industrial wastes. To avoid large titrn vols, use aliquot contg <25 mg  $\text{CaCO}_3$ .

Synthetic  $\text{H}_2\text{O}$  samples contg exact increments of Ca and Mg salts analyzed by 43 analysts in 19 laboratories showed the following results:

Increment, total hardness as mg $\text{CaCO}_3/\text{L}$	Std deviation		Bias	
	%	mg $\text{CaCO}_3/\text{L}$	%	mg $\text{CaCO}_3/\text{L}$
31	9.4	2.9	-0.87	- 0.003
33	7.6	2.5	-0.73	- 0.24
182	2.7	4.9	-0.19	- 0.4
194	1.5	3.0	-1.04	- 2.0
417	2.3	9.7	-3.35	-13.0
444	2.0	8.7	-3.23	-14.3

**33.083****Reagents**

(a) *Buffer soln.*—Dissolve 16.9 g  $\text{NH}_4\text{Cl}$  in 143 mL  $\text{NH}_4\text{OH}$ , add 1.25 g  $\text{MgEDTA}$ , and dil. to 250 mL with  $\text{H}_2\text{O}$ . (1.179 g  $\text{Na}_2\text{EDTA} \cdot 2\text{H}_2\text{O}$  and 0.780 g  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$  or 0.644 g  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$  dissolved in 50 mL  $\text{H}_2\text{O}$  may be substituted for 1.25 g  $\text{MgEDTA}$ .) Store in tightly stoppered Pyrex or plastic bottle. Dispense from bulb-operated pipet. Discard after 1 month or when 1–2 mL added to sample fails to produce pH  $10.0 \pm 0.1$  at end point of titrn.

(b) *Indicator.*—Mix 0.5 g eriochrome black T and 100 g  $\text{NaCl}$  to prep. dry powd mixt. If end point change is not clear and sharp, prep. new mixt.

(c) *EDTA std soln.*—0.01M. Weigh 3.723 g  $\text{Na}_2\text{EDTA} \cdot 2\text{H}_2\text{O}$  and dil. to 1 L with  $\text{H}_2\text{O}$ . Stdze against Ca std soln as in 33.084. Store in polyethylene bottle and restdze periodically.

(d) *Calcium std soln.*—1.000 mg  $\text{CaCO}_3/\text{mL}$ . Weigh 1.000 g  $\text{CaCO}_3$  (primary std or special reagent low in heavy metals, alkalis, and Mg) into 500 mL erlenmeyer. Place funnel in neck and add, little at a time,  $\text{HCl}$  (1+1) until all  $\text{CaCO}_3$  has dissolved. Add 200 mL  $\text{H}_2\text{O}$  and boil few min to expel  $\text{CO}_2$ . Cool, add few drops Me red indicator, and adjust to intermediate orange with 3N  $\text{NH}_4\text{OH}$  or  $\text{HCl}$  (1+1), as required. Transfer quant. to 1 L vol. flask and dil. to vol.

**33.084****Determination**

Dil. 25 mL sample (or such vol. as to require <15 mL titrant) to ca 50 mL with  $\text{H}_2\text{O}$  in porcelain casserole, add 1–2 mL buffer soln, 250 mg  $\text{NaCN}$  (pH of soln should be  $10 \pm 0.1$ ), and ca 200 mg indicator powder, and titr. with EDTA std soln slowly, with continuous stirring, until last reddish tinge disappears, adding last few drops at 3–5 sec intervals. Color at end point is blue in daylight and under daylight fluorescent lamp. Complete titrn within 5 min from time of buffer addn.

For waters of low hardness (<5 mg/L), use 100–1000 mL sample, proportionately larger amts of reagents, microburet, and blank of distd  $\text{H}_2\text{O}$  equal to sample vol.

Hardness (EDTA) as mg  $\text{CaCO}_3/\text{L} = T \times B \times 1000/\text{mL sample}$ , where  $T$  = mL EDTA std soln and  $B$  = mg  $\text{CaCO}_3$  equiv. to 1.00 mL EDTA std soln.

**33.085 Aluminum—Official Final Action**

To obtain wt  $\text{Al}_2\text{O}_3$ , in absence of phosphates, subtract from wt  $\text{Fe}_2\text{O}_3$  and  $\text{Al}_2\text{O}_3$ , 33.078, the Fe, 33.079 or 33.080, calcd as  $\text{Fe}_2\text{O}_3$ . Calc. as Al.

**33.086 Calcium—Official Final Action**

Conc. *Soln Y*, 33.078, to 150–200 mL, and to this soln, contg equiv. of  $\leq 0.6$  g  $\text{CaO}$  or 1 g  $\text{Mg}_2\text{P}_2\text{O}_7$ , add 1–2 g  $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$

and enough  $\text{HCl}$  (1+1) to clear soln. Heat to bp and neutze with  $\text{NH}_4\text{OH}$ , stirring constantly. Add  $\text{NH}_4\text{OH}$  in slight excess and let stand 3 hr in warm place. Filter supernate and wash ppt once or twice by decantation with 1%  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln. Dissolve ppt in  $\text{HCl}$  (1+1), dil. to 100–200 mL, add little more  $\text{H}_2\text{C}_2\text{O}_4$ , and ppt as above. After letting ppt stand 3 hr, filter, wash with 1%  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln, dry, ignite, heat over blast lamp at  $\geq 950^\circ$ , and weigh as  $\text{CaO}$  and  $\text{SrO}$ . From this wt subtract wt  $\text{SrO}$  equiv. to the Sr, 33.087. Difference is wt  $\text{CaO}$ . Calc. as Ca. Designate combined filtrates and washings as *Soln Z*.

As check on  $\text{CaO}$ , evap. to dryness filtrate from the  $\text{Sr}(\text{NO}_3)_2$  in 33.087, beginning "Filter, and wash with ether-alcohol mixt. . . ." Dissolve the  $\text{Ca}(\text{NO}_3)_2$  in  $\text{H}_2\text{O}$ , ppt as oxalate, filter, wash, ignite at  $950^\circ$ , and weigh as  $\text{CaO}$ .  $\text{CaO} \times 0.7147 = \text{Ca}$ .

**33.087 Strontium (7)—Official Final Action**

Dissolve oxides, 33.086, in  $\text{HNO}_3$  (1+1) and test with spectro-scope for Sr. If Sr is present, transfer  $\text{HNO}_3$  soln to small erlenmeyer. Evap. nearly to dryness over low flame, and heat 1–2 hr at  $150\text{--}160^\circ$  after  $\text{H}_2\text{O}$  is evapd. Break up dried material with stirring rod and add 10–15 mL mixt. of absolute alcohol and ether (1+1) to dissolve the  $\text{Ca}(\text{NO}_3)_2$ . Cork flask and let stand with frequent shaking  $\geq 2$  hr. Decant soln thru 5.5 cm filter, reserving filtrate. Wash residue several times by decantation with small portions of the ether-alcohol mixt. Dry residue and paper, and repeatedly wash paper with small portions of hot  $\text{H}_2\text{O}$ , collecting filtrate in flask contg main portion of  $\text{Sr}(\text{NO}_3)_2$  residue. Add 1 or 2 drops  $\text{HNO}_3$  (1+1), evap., dry, pulverize, and treat with 10–15 mL ether-alcohol mixt. Cork flask and let stand ca 12 hr, shaking occasionally.

Filter, and wash with ether-alcohol mixt. until few drops filtrate evapd on watch glass leave practically no residue. Dry paper and ppt. Dissolve  $\text{Sr}(\text{NO}_3)_2$  in few mL hot  $\text{H}_2\text{O}$ . Add few drops  $\text{H}_2\text{SO}_4$  and then add vol. alcohol equal to vol. soln and let stand 12 hr. Filter, ignite, weigh as  $\text{SrSO}_4$ , and calc. to Sr. Test spectroscopically for Ca and Ba. If these elements are present, det. amt and make necessary correction.

**33.088 Magnesium—Official Final Action**

Conc. *Soln Z*, 33.086, to 200 mL, acidify with  $\text{HCl}$  (1+1), and add 2–3 g  $(\text{NH}_4)_2\text{HPO}_4$  and enough  $\text{HCl}$  (1+1) to produce clear soln when all  $(\text{NH}_4)_2\text{HPO}_4$  is dissolved. When cold, make slightly alk. with  $\text{NH}_4\text{OH}$ , stirring constantly. Add 2 mL excess of  $\text{NH}_4\text{OH}$  and let stand ca 12 hr. Filter supernate and wash 4 times by decantation with  $\text{NH}_4\text{OH}$  (1+10). Dissolve ppt in  $\text{HCl}$  (1+1), dil. to ca 150 mL, add little  $(\text{NH}_4)_2\text{HPO}_4$ , and ppt with  $\text{NH}_4\text{OH}$  as before. Let stand 12 hr, filter, wash  $\text{Cl}$ -free with  $\text{NH}_4\text{OH}$  (1+10), place in porcelain crucible, ignite, heat over blast lamp, and weigh as  $\text{Mg}_2\text{P}_2\text{O}_7$ . Calc. to Mg.  $\text{Mg}_2\text{P}_2\text{O}_7 \times 0.21842 = \text{Mg}$ .

**Cadmium, Chromium, Copper, Iron, Lead, Magnesium,  
Manganese, Silver, Zinc**

**Atomic Absorption Method (8)  
Official First Action**

**33.089****Principle**

Metals in soln are detd directly by AA spectrophotometry; suspended metals are sepd by membrane filtration, or suspension is dissolved and analyzed; Pb and Cd in low concn are chelated, concd, and then extd with org. solv. prior to AA detn. Applicable to surface and saline waters, and domestic and industrial wastes. Three synthetic water samples contg between 0.05 and 1.0 mg each metal/L analyzed by 8–23 laboratories showed results given in Table 33.02.

## 33.090

## Apparatus

(Use Pyrex glassware exclusively; clean thoroly with detergent and H<sub>2</sub>O; rinse with chromic acid cleaning soln, H<sub>2</sub>O, dil. HNO<sub>3</sub>, and H<sub>2</sub>O, in that order. Use deionized distd H<sub>2</sub>O wherever H<sub>2</sub>O is specified in method.)

**Atomic absorption spectrophotometer.**—Spectrophtr capable of operating at conditions given in Table 33:03. Operator must become familiar with settings and operations of his app., using table only as guide. Use Boling burner for aq. solns, and premix burner with solv. (Caution: See 51.006).

## 33.091

## Reagents

- (a) *Deionized distilled water.*—See 33.053(a).  
 (b) *Nitric acid.*—Dil. 500 mL redistd HNO<sub>3</sub> to 1 L with H<sub>2</sub>O. (Caution: Perform distn in hood with protective sash in place.)  
 (c) *Hydrochloric acid.*—Dil. 500 mL HCl to 1 L with H<sub>2</sub>O and distil in all-Pyrex app.  
 (d) *Metal std solns.*—(1) *Stock solns.*—Accurately weigh amt of metal specified in Table 33:04 into beaker and add dissolving medium. When metal is completely dissolved, transfer quant.

Zn	213.9	Oxidizing air-C <sub>2</sub> H <sub>2</sub>	0.1 - 2

<sup>a</sup> With 1% La soln.

to 1 L vol. flask and dil. to vol. with H<sub>2</sub>O. (2) *Working solns.*—Prep. daily. Dil. aliquots of stock solns with H<sub>2</sub>O to make ≥4 std solns of each element within range of detn, Table 33:03. Add 1.5 mL HNO<sub>3</sub>/L to all working std solns before dilg to vol. Add 1 mL LaCl<sub>3</sub>/10 mL Mg working std soln.

(e) *Lanthanum stock soln.*—50 g La/L ca 5% HCl. Slowly add 250 mL HCl to 58.65 g La<sub>2</sub>O<sub>3</sub> (99.99%, Ventron Corp., Alfa Products, 8 Congress St, Beverly, MA 01915, or equiv.), dissolve, and dil. to 1 L.

(f) *Ammonium pyrrolidine dithiocarbamate (APDC) soln.*—Dissolve 1 g APDC in 100 mL H<sub>2</sub>O. Prep. fresh daily.

## 33.092

## Preparation of Sample

(a) *Dissolved metals.*—As soon as practicable after collection, filter known vol. sample thru 0.45 μm membrane. Use first 50–100 mL to rinse flask and discard. Collect filtrate and preserve soln by adding 3 mL HNO<sub>3</sub> (1+1)/L.

(b) *Suspended metals.*—Transfer residue and membrane from (a) to 250 mL beaker and add 3 mL HNO<sub>3</sub>. Cover with watch glass and heat gently to dissolve membrane. Increase heat and evap. to dryness. Cool, and add 3 mL HNO<sub>3</sub>, and heat until digestion is complete, generally indicated by light colored residue. Add 2 mL HCl (1+1), and heat gently to dissolve residue. Wash watch glass and beaker with H<sub>2</sub>O and filter. Wash filter and discard. Dil. filtrate with H<sub>2</sub>O to concn within range of instrument.

(c) *Total metal.*—Transfer aliquot of well mixed sample to beaker and add 3 mL HNO<sub>3</sub>. Heat, and evap. to dryness. (Do not boil.) Continue as in (b), beginning "Cool, and add 3 mL HNO<sub>3</sub>, ..."

## 33.093

## Determination

(P interference in Mg detn is eliminated by adding La stock soln to sample and working std solns so that final dilns contain 1% La.)

(a) *General method.*—Set up instrument as in Table 33:03, or previously established optimum settings. Secondary or less sensitive lines (*Spectrochim Acta* 17, 710(1961)) may be used to reduce necessary diln, if desired. Read 4 std solns within range before and after each group of 6–12 samples, and re-establish 0.4 each time. Prep. calibration curve from av. of each std before and after sample group. Read sample concn from plot of A against mg/L.

(b) *Special extraction method.*—When Pb or Cd concn is too low for direct detn, transfer sample aliquot to 250 mL beaker and dil. to 100 mL with H<sub>2</sub>O. Prep. blank and stds in same manner. Adjust pH of sample and std solns to 2.5 with HCl, using pH meter. Transfer quant. to 200 mL vol. flask, add 2.5 mL APDC soln, and mix. Add 10 mL methyl isobutyl ketone and shake vigorously 1 min. Let layers sep.; then add H<sub>2</sub>O until ketone layer is in neck of flask. (Centrfg may be necessary.) Aspirate ketone layer and record readings of stds and samples

**Table 33:04 Preparation of Metal Standard Solutions**

Metal <sup>a</sup>	Wt, g	Compd	Dissolving medium (1 L total)
Cd	1.142	CdO	5 mL redistd HNO <sub>3</sub>
Cr	1.923	CrO <sub>3</sub>	H <sub>2</sub> O + 10 mL redistd HNO <sub>3</sub>
Cu	1.000	Cu, electrolytic	5 mL redistd HNO <sub>3</sub>
Fe	1.000	Fe wire	5 mL redistd HNO <sub>3</sub>
Pb	1.599	Pb(NO <sub>3</sub> ) <sub>2</sub>	H <sub>2</sub> O + 10 mL redistd HNO <sub>3</sub>
Mg	0.829	MgO	10 mL redistd HNO <sub>3</sub> <sup>b</sup>
Mn	1.583	MnO <sub>2</sub>	10 mL HCl
Ag	1.575	AgNO <sub>3</sub>	H <sub>2</sub> O + 10 mL redistd HNO <sub>3</sub>
Zn	1.000	Zn	10 mL HNO <sub>3</sub>

<sup>a</sup> Final concn = 1000 mg/L except for Mg (500 mg/L).

<sup>b</sup> Add 1 mL La stock soln to 10 mL working std soln.

against blank. (Fuel-to-air ratio should be adjusted to as blue a flame as possible, since org. solv. adds to fuel supply.) Prep. calibration curve from av. of each std and read sample concn from plot (mg/L).

**33.094****Calculations**

(a) *General method.*—mg Metal/L = (mg metal in aliquot/L)  $\times F$  where  $F$  = final diln/mL aliquot.

(b) *Special extraction method.*—mg Metal/L = mg metal in aliquot/L.

**Mercury****Flameless Atomic Absorption Method (9)  
Official Final Action****33.095****Principle**

Org. Hg is oxidized to inorg. Hg by  $\text{KMnO}_4$ ,  $\text{K}_2\text{S}_2\text{O}_8$ , and heat. The Hg is reduced to elemental state with stannous ion, and Hg is aerated from soln thru measuring cell in closed system.  $A$  is measured in AA spectrophtr.

Method is applicable to detn of 0.2–10  $\mu\text{g}$  Hg/L of drinking, surface, and saline waters and domestic and industrial wastes. Interference from Cl or  $\leq 20$  mg S/L is eliminated by oxidn with  $\text{KMnO}_4$ ; 10 mg Cu/L does not interfere. Analysis without reagents will det. if absorbing interfering volatile org. compds are present.

Natural waters analyzed by 76–82 laboratories showed the following results on exact increments of org. and inorg. Hg compds:

Added, $\mu\text{g}$ Hg/L	Std deviation		Bias	
	%	$\mu\text{g}$ Hg/L	%	$\mu\text{g}$ Hg/L
0.21	79	0.28	+66	+0.14
0.27	67	0.28	+53	+0.14
0.51	79	0.54	+32	+0.16
0.60	55	0.39	+18	+0.11
3.4	44	1.5	+ 0.34	0.0
4.1	29	1.1	- 7.1	-0.3
8.8	42	3.7	- 0.4	0.0
9.6	39	3.6	- 5.2	-0.5

**33.096****Apparatus**

(Rinse all glassware with chromic acid cleaning soln or  $\text{HNO}_3$  (1+1) and Hg-free  $\text{H}_2\text{O}$  before use.)

(a) *Atomic absorption spectrophotometer.*—Equipped with Hg hollow cathode lamp and gas flow-thru cell (Fig. 33.01), 115  $\times$  25 (id) mm with quartz windows cemented in place. Use at 253.7 nm with operating conditions specified by manufacturer.

(b) *Air pump.*—Peristaltic pump capable of delivering ca 1 L air/min. Use Tygon tubing for all connections.

(c) *Flowmeter.*—Capable of measuring air flow of 1 L/min.

(d) *Lamp.*—Small reading lamp contg 60 watt bulb to prevent condensation of moisture inside cell. Position lamp to warm cell (See Fig. 33.01.). Alternatively, use  $\text{Mg}(\text{ClO}_4)_2$ -filled drying tube, 33.097(a).

(e) *Digestion flask.*—250 mL flat-bottom boiling flask fitted with 2-hole rubber stopper. Use straight glass frit of coarse porosity for gas inlet.

**33.097****Reagents**

(a) *Magnesium perchlorate.*—Place 20 g  $\text{Mg}(\text{ClO}_4)_2$  in 150  $\times$  18 (id) mm drying tube (Fig. 33.01); replace as needed. (Caution: See 51.064.)

(b) *Mercury absorbing media.*—Add one of following to 250 mL gas-washing bottle fitted with 2-hole rubber stopper and

attach to aeration app. as by-pass (See Fig. 33.01): (1) *Potassium permanganate-sulfuric acid soln.*—Equal vols 0.1N  $\text{KMnO}_4$  and  $\text{H}_2\text{SO}_4$  (1+9). (2) *Iodine-potassium iodide soln.*—0.25%  $\text{I}_2$ -3% KI soln. Alternatively, vent Hg vapor into exhaust hood.

(c) *Sodium chloride-hydroxylamine sulfate soln.*—Dissolve 120 g NaCl and 120 g  $(\text{NH}_2\text{OH})_2\cdot\text{H}_2\text{SO}_4$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(d) *Stannous sulfate soln.*—Disperse 100 g  $\text{SnSO}_4$  in  $\text{H}_2\text{O}$  contg 14 mL  $\text{H}_2\text{SO}_4$  and dil. to 1 L. Stir suspension with mag. stirrer continuously during use.

(e) *Mercury std solns.*—(1) *Stock soln.*—1000  $\mu\text{g}$ /mL. Dissolve 0.1354 g  $\text{HgCl}_2$  in 75 mL  $\text{H}_2\text{O}$ , add 10 mL  $\text{HNO}_3$ , and dil. to 100 mL with  $\text{H}_2\text{O}$ . (2) *Intermediate soln.*—10  $\mu\text{g}$ /mL. Pipet 10 mL stock soln into 500 mL  $\text{H}_2\text{O}$ , add 2 mL  $\text{HNO}_3$ , and dil. to 1 L with  $\text{H}_2\text{O}$ . Prep. fresh daily. (3) *Working soln.*—0.1  $\mu\text{g}$ /mL. Pipet 10 mL intermediate soln into 500 mL  $\text{H}_2\text{O}$ , add 2 mL  $\text{HNO}_3$ , and dil. to 1 L with  $\text{H}_2\text{O}$ . Prep. fresh daily.

**33.098****Preparation of Sample**

(a) *Dissolved mercury.*—Proceed as in 33.092(a).

(b) *Suspended mercury.*—Transfer residue and membrane from (a) to digestion flask and proceed as in 33.099.

(c) *Total mercury.*—Preserve soln by adding 2 mL  $\text{HNO}_3$ /L and proceed as in 33.099.

**33.099****Determination**

Transfer 100 mL sample or aliquot dild to 100 mL, contg  $\leq 1.0$   $\mu\text{g}$  Hg, to digestion flask. Slowly add 5 mL  $\text{H}_2\text{SO}_4$  and 2.5 mL  $\text{HNO}_3$ , with mixing. Add 15 mL 5%  $\text{KMnO}_4$  soln, shake, and add addnl  $\text{KMnO}_4$  until purple color lasts  $\geq 15$  min. Add 8 mL 5%  $\text{K}_2\text{S}_2\text{O}_8$  soln, heat 2 hr in 95°  $\text{H}_2\text{O}$  bath, and cool to room temp.

Adjust output of pump to ca 1 L/min and connect app. as in Fig. 33.01, except for gas inlet. With pump working and spectrophtr zeroed, add 6 mL  $\text{NaCl}(\text{NH}_2\text{OH})_2\cdot\text{H}_2\text{SO}_4$  soln to reduce excess  $\text{KMnO}_4$  (purple color disappears); let stand 30 sec, and add 5 mL  $\text{SnSO}_4$  soln. Immediately connect digestion flask gas inlet to aeration app. and aerate without manual agitation.  $A$  will reach max. within 30 sec. Record  $A$ . When pen levels off (ca 1 min), open by-pass valve and continue aeration until  $A$  returns to min. value. Close bypass valve, remove stopper and frit from digestion flask, and continue aeration to flush system.

Check for interfering volatile org. compds by placing same vol. sample or dild sample into digestion flask. Connect flask to aeration app. and aerate without manual agitation and measure  $A$  after 30 sec. Subtract  $A$  from reading obtained on sample with reagents added.

Prep. std curve by dilg 0, 0.5, 1.0, 2.0, 5.0, and 10.0 mL aliquots Hg working std soln to 100 mL, and adding to series of digestion flasks. Proceed as in par. 1, beginning "Slowly add 5 mL  $\text{H}_2\text{SO}_4$  ..."

Plot  $A$  against  $\mu\text{g}$  Hg. Det.  $\mu\text{g}$  Hg in sample from curve.

$$\mu\text{g Hg/L} = W \times (1000/V),$$

where  $W$  =  $\mu\text{g}$  Hg in sample and  $V$  = mL sample.

**Barium—Official Final Action**

(It is not necessary to look for Ba if sulfate is present in appreciable amt unless sample contains large amt of bicarbonate or chloride, which may hold in soln small amts of both sulfate and Ba.)

**Gravimetric Method (10)****33.100****Reagents**

(a) *Ammonium dichromate soln.*—Dissolve 100 g of the  $\text{SO}_4$ -free salt in  $\text{H}_2\text{O}$  and dil. to 1 L.

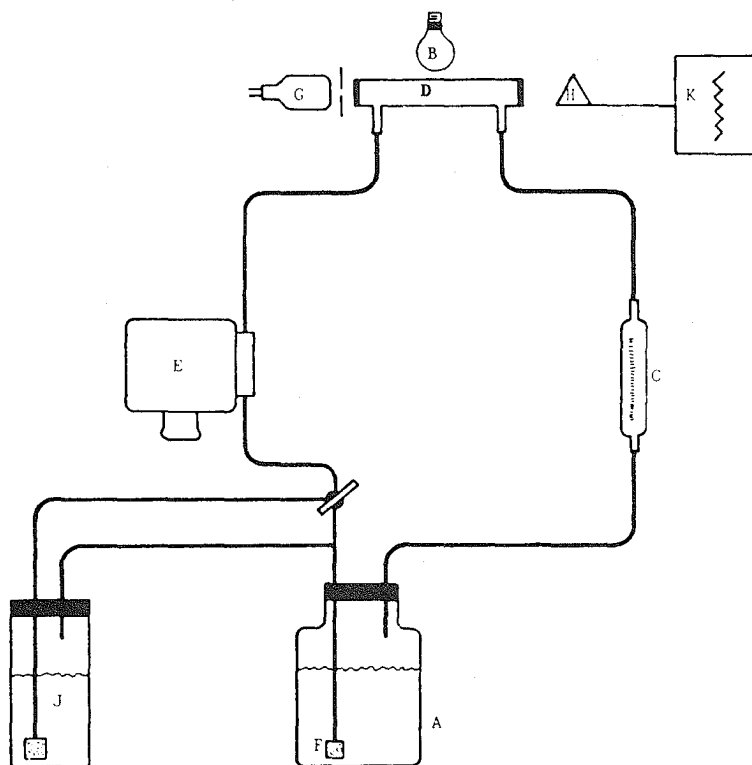

FIG. 33:01—Apparatus for determination of mercury by flameless atomic absorption closed recirculating system: A, reaction flask; B, 60 watt light bulb; C, rotameter, 1 L air/min; D, absorption cell with quartz windows; E, air pump, 1 L air/min; F, glass tube with fritted end; G, hollow cathode Hg lamp; H, atomic absorption detector; J, gas washing bottle contg 0.25%  $I_2$  in 3% KI soln; K, recorder, any compatible model.

(b) *Ammonium acetate soln.*—Dissolve 300 g of the salt in  $H_2O$ , neutze with  $NH_4OH$ , and dil. to 1 L.

(c) *Dilute ammonium acetate wash soln.*—Dil. 20 mL (b) to 1 L.

(Reaction of acetate solns should be alk. rather than acid.)

### 33.101

#### Determination

Acidify 1–5 L portion of sample with HCl and conc. to ca 200 mL. (If ppt forms, filter off and test for Ba.) Add ca 0.5 g  $NH_4Cl$ , and ppt Fe and Al with  $NH_4OH$ . Boil, filter, and wash. To filtrate, add excess (10 mL)  $NH_4OAc$  soln, (b), keeping total vol. ca 200 mL. Heat to bp, and add, with stirring, ca 5 mL  $(NH_4)_2Cr_2O_7$  soln. Let settle and cool. Decant clear liq. thru filter and wash ppt by decantation with dil.  $NH_4OAc$  soln until filtrate is no longer perceptibly colored (ca 100 mL wash soln).

Place beaker under funnel, dissolve ppt on paper with warm  $HNO_3$  (1+1), using as little as possible, and wash paper. Add little more acid to dissolve ppt in beaker, and then  $NH_4OH$  until ppt that forms no longer redissolves. Heat to bp; add, with stirring, 10 mL  $NH_4OAc$  soln, (b), and 2 mL  $(NH_4)_2Cr_2O_7$  soln; let cool slowly, and wash ppt free of chromate with dil.  $NH_4OAc$  soln by decantation and filtration. Dry ppt, ignite moderately to const wt, and weigh as  $BaCrO_4$ . Calc. as Ba, using factor 0.5421.

### 33.102 Volumetric Method

Proceed as in 33.101 thru "... wash ppt free of chromate with dil.  $NH_4OAc$  soln ..." (after second pptn). Dissolve ppt in ca 10 mL HCl (1+1) and hot  $H_2O$ . Wash filter, dil. soln to ca 400 mL, and add ca 50 mL freshly prepd 10% KI soln. Mix carefully and titr. liberated  $I_2$  after 3 or 4 min with 0.1N  $Na_2S_2O_3$ . 1 mL 0.1N  $Na_2S_2O_3$  = 4.578 mg Ba.

### Potassium (1, 2)

#### Atomic Absorption Method

### 33.103

#### Principle

Method is applicable to detn of 0.01–2 mg K/L of surface and saline waters and domestic and industrial wastes. Na may interfere if present at much higher levels than K but effect may be avoided by approx. matching Na concn of stds with that of sample.

Synthetic  $H_2O$  analyzed by 19 analysts in 10 laboratories showed the following results on exact increments of K salt:

Added, mg K/L	Std deviation		Bias	
	%	mg K/L	%	mg K/L
1.5	11	0.17	+4.8	0.07
1.4	16	0.22	+6.6	0.09
8.0	8	0.64	+7.6	0.60
7.5	9	0.66	+8.7	0.64
20.0	6	1.11	+7.4	1.5
19.0	8	1.58	+7.4	1.4

### 33.104

#### Apparatus

*Atomic absorption spectrophotometer.*—Equipped with Boln-type burner, set at 766.5 nm.

### 33.105

#### Reagents

(a) *Deionized distilled water.*—See 33.053(a). Use for prepn of reagents and stds, and as diln  $H_2O$ .

(b) *Potassium std solns.*—(1) *Stock soln.*—100 mg K/L. Dissolve 0.1907 g KCl, dried at  $110^\circ$ , in  $H_2O$ , and dil. to 1 L. (2) *Working solns.*—Prep. dil. std solns in range of interest at time of analysis. If  $HNO_3$  is used to preserve samples, add corresponding amt to working std solns.

## 33.106

## Determination

(Caution: See 51.006.)

Follow manufacturer's instructions for app. operation. Optimize conditions for max. absorption and stability. Beginning with blank and working toward highest std, aspirate solns and record readings. Repeat std solns and samples enough times to secure reliable av. reading for each soln. If necessary, dil. sample with H<sub>2</sub>O to bring into range for direct reading.

For instruments which read directly in concn, set curve corrector to read out proper concn. Otherwise, plot calibration curve, using concn range producing absorption of 0–80%. Before plotting, convert % absorption to absorbance:  $A = \log(100/\%T) = 2 - \log \%T$ , where  $\%T = 100 - \% \text{ absorption}$ . Curves are frequently nonlinear. Increase number of stds in that portion of curve.

Read mg K/L from calibration curve or directly from readout system.

mg K/L in sample = (mg K/L) in aliquot  $\times D$ ;  $D = (\text{mL aliquot} + \text{mL H}_2\text{O added})/\text{mL aliquot}$ .

## Sodium (1, 2)

## Atomic Absorption Method

## 33.107

## Principle

Method is applicable to detn of 1–200 mg Na/L in surface and saline waters and domestic and industrial wastes.

Synthetic H<sub>2</sub>O analyzed by 22 analysts in 12 laboratories showed the following results on exact increments of Na salts:

Added, mg Na/L	Std deviation		Bias	
	%	mg Na/L	%	mg Na/L
4.1	3.4	0.14	+1.9	0.07
3.8	5.0	0.19	+2.9	0.11
55.0	3.6	1.99	+0.9	0.5
52.0	3.7	1.93	+0.8	0.4
155	2.4	3.75	+0.0	0.0
149	2.7	3.97	–0.1	0.0

## 33.108

## Apparatus

Atomic absorption spectrophotometer.—See 33.104. Use Na hollow cathode lamp, 330.2 nm, Belling burner, and oxidizing air-C<sub>2</sub>H<sub>2</sub> flame. For greater sensitivity (0.005–0.2 mg/L), use 589.0 nm line.

## 33.109

## Reagents

(a) Deionized distilled water.—See 33.053(a).

(b) Sodium std solns.—(1) Stock soln.—1000 mg Na/L. Dissolve 2.542 g NaCl, dried at 140°, in H<sub>2</sub>O, and dil. to 1 L. (2) Working solns.—Prep. dil. std solns in range of interest at time of analysis. If HNO<sub>3</sub> is used to preserve samples, add corresponding amt to working std solns.

## 33.110

## Determination

Proceed as in 33.106, using Na parameters and std solns.

## Phosphorus (1, 4)

## 33.111

## Definitions

(a) Phosphorus.—(P). All P present in sample, regardless of form, measured by persulfate digestion method. (1) Orthophosphate.—(P, ortho). Inorg. P, (PO<sub>4</sub><sup>3–</sup>), in sample as measured by direct colorimetric analysis. (2) Hydrolyzable phosphorus.—(P, hydro). P as measured by H<sub>2</sub>SO<sub>4</sub> hydrolysis method minus orthophosphate; includes polyphosphates, (P<sub>2</sub>O<sub>7</sub>)<sup>4–</sup>, (P<sub>3</sub>O<sub>10</sub>)<sup>5–</sup>,

and some org. P. (3) Organic phosphorus.—(P, org) = P – [(P, ortho) + (P, hydro)].

(b) Dissolved phosphorus.—(P-D). P present in filtrate of sample filtered thru 0.45  $\mu\text{m}$  pore filter, measured by persulfate digestion method. (1) Dissolved orthophosphate.—(P-D, ortho). Inorg. P as measured by direct colorimetric method. (2) Dissolved hydrolyzable phosphorus.—(P-D, hydro). P as measured by H<sub>2</sub>SO<sub>4</sub> hydrolysis – (P-D, ortho). (3) Dissolved organic phosphorus.—(P-D, org) = (P-D) – [(P-D, ortho) + (P-D, hydro)].

(c) Insoluble phosphorus.—(P-I). When sufficient amt is present, calc. following: (1) P-I = (P) – (P-D). (2) Insoluble orthophosphate.—(P-I, ortho) = [(P, ortho) – (P-D, ortho)]. (3) Insoluble hydrolyzable phosphorus.—(P-I, hydro) = [(P, hydro) – (P-D, hydro)]. (4) Insoluble organic phosphorus.—(P-I, org) = [(P, org) – (P-D, org)].

## 33.112

## Principle

Ammonium molybdate and K antimonyl tartrate react in acid soln with dil. solns of PO<sub>4</sub><sup>3–</sup> to form Sb phosphomolybdate complex which is reduced to intensely blue complexes by ascorbic acid. Method is specific for orthophosphate and for compds that can be converted to orthophosphate. Various forms of P are detd, depending on pretreatment, in range 0.01–0.5 mg P/L.

Method is applicable to surface and saline waters and domestic and industrial wastes. Most commonly measured forms are total P, dissolved P, orthophosphate, and dissolved orthophosphate. Hydrolyzable P is normally found only in sewage-type samples. Concns of Cu, Fe, silicate, and arsenate many times greater than those in sea water do not interfere. Interference of HgCl<sub>2</sub>, used as preservative, is overcome by adding min. of 50 mg NaCl/L to samples.

Natural H<sub>2</sub>O analyzed by 33 analysts in 19 laboratories showed following results on exact increments of org. phosphate:

Added, mg P/L	Std deviation		Bias	
	%	mg P/L	%	mg P/L
0.110	30	0.033	+ 3.1	+0.003
0.132	39	0.051	+12.0	+0.016
0.772	17	0.130	+ 3.0	+0.023
0.882	15	0.128	– 0.9	–0.008

Natural H<sub>2</sub>O analyzed by 26 analysts in 16 laboratories showed following results on exact increments of orthophosphate:

Added, mg P/L	Std deviation		Bias	
	%	mg P/L	%	mg P/L
0.029	34	0.010	–5.0	–0.001
0.038	21	0.008	–6.0	–0.002
0.335	5.4	0.018	–2.8	–0.009
0.383	6.0	0.023	–1.8	–0.007

## 33.113

## Apparatus

(a) Glassware.—Wash all glassware with hot HCl (1+1) and rinse with H<sub>2</sub>O. Remove last traces of P by filling with H<sub>2</sub>O contg all color-developing reagents. Use treated glassware only for P detns and after use, rinse with H<sub>2</sub>O and keep covered until used again. Under such conditions, hot HCl and reagent treatment need be applied only occasionally. Never use com. detergents on glassware.

(b) Photometer.—Spectrophtr or filter photometer measuring at 880 nm, using  $\geq 2.5$  cm light path.

## 33.114

## Reagents

- (a) *Dilute sulfuric acid*.—5*N*. Dil. 70 mL  $\text{H}_2\text{SO}_4$  to 500 mL.
- (b) *Potassium antimonyl tartrate soln.*—Weigh 1.3715 g  $\text{K(SbO)C}_4\text{H}_4\text{O}_6 \cdot 0.5\text{H}_2\text{O}$ , dissolve in ca 400 mL  $\text{H}_2\text{O}$ , and dil. to 500 mL. Store in dark g-s bottle at 4°.
- (c) *Ammonium molybdate soln.*—Dissolve 20 g  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in 500 mL  $\text{H}_2\text{O}$ . Store in plastic bottle at 4°.
- (d) *Ascorbic acid soln.*—0.1*M*. Dissolve 1.76 g in 100 mL  $\text{H}_2\text{O}$ . Stable 1 week at 4°.
- (e) *Combined reagent*.—Warm reagents (b)–(d) to room temp., and add with mixing in following order: 50 mL 5*N*  $\text{H}_2\text{SO}_4$ , 5 mL K antimonyl tartrate soln, 15 mL  $\text{NH}_4$  molybdate soln, and 30 mL ascorbic acid soln. If turbidity forms, shake, and let stand few min before proceeding. Stable 1 week at 4°.
- (f) *Hydrolyzing acid soln.*—Slowly add 310 mL  $\text{H}_2\text{SO}_4$  to 600 mL  $\text{H}_2\text{O}$ , cool, and dil. to 1 L.
- (g) *Phosphorus std solns.*—(1) *Stock soln.*—50 mg P/L. Dissolve and dil. 0.2197 g  $\text{KH}_2\text{PO}_4$ , dried at 105°, to 1 L. (2) *Intermediate soln.*—0.5 mg/L. Dil. 10.0 mL stock soln to 1 L. (3) *Working solns.*—Dil. 0.0, 1.0, 3.0, 5.0, 10.0, 20.0, 30.0, 40.0, and 50.0 mL intermediate soln to 50 mL to prep. std solns contg 0.0, 0.01, 0.03, 0.05, 0.10, 0.20, 0.30, 0.40, and 0.50 mg P/L.

## 33.115

## Determination

Store samples in plastic or Pyrex containers. If analysis cannot be performed on day of collection, preserve with 40 mg  $\text{HgCl}_2/\text{L}$  and refrigerate at 4°. In such case, add 50 mg  $\text{NaCl}/\text{L}$  before analysis.

(a) *Phosphorus*.—Add 1 mL hydrolyzing acid soln to 50 mL sample in 125 mL erlenmeyer. Add 0.4 g  $\text{NH}_4$  persulfate, and boil gently on preheated hot plate 30–40 min or until vol is 10 mL. Do not let sample evap. to dryness. Alternatively, autoclave 30 min at 121°. Cool, add few drops phthln, adjust to pink with 1*N*  $\text{NaOH}$ , and then to colorless with 1 drop hydrolyzing acid soln. Cool, and dil. to 50.0 mL. If turbid, filter. Proceed as in (c), beginning "Add 8.0 mL combined reagent, . . ."

(b) *Hydrolyzable phosphorus*.—Proceed as in (a), except omit addn of  $\text{NH}_4$  persulfate.

(c) *Orthophosphate*.—Add 1 drop phthln to 50.0 mL sample; if red develops, add hydrolyzing acid soln dropwise until color is discharged. Add 8.0 mL combined reagent, and mix thoroly. After specific time within 10–30 min, measure *A* at 880 nm against reagent blank as ref.

(d) *Std curve and calculation*.—Process stds and blank as in (c) and plot *A* against mg P/L. Include blank and  $\geq 2$  std solns with each series of samples. If stds do not agree with std curve within  $\pm 2\%$ , prep. new std curve. Obtain mg P/L sample directly from std curve.

## Automated Method (1)

## 33.116

## Principle

See 33.111–33.115. Developed color is measured automatically.

Natural  $\text{H}_2\text{O}$  analyzed by 6 laboratories showed following results on exact increments of orthophosphate:

Added, mg P/L	Std deviation		Bias	
	%	mg P/L	%	mg P/L
0.04	47	0.019	+16.7	+0.007
0.04	35	0.014	– 8.3	–0.003
0.29	30	0.087	–15.5	–0.05
0.30	22	0.066	–12.8	–0.04

## 33.117

## Apparatus

- (a) *Glassware*.—See 33.113(a).
- (b) *Automatic analyzer*.—AutoAnalyzer with following modules (Technicon Instruments Corp.): Sampler I, manifold, proportioning pump, 50° bath, colorimeter with 50 mm tubular flowcell and 650 nm filter, and recorder. See Fig. 33:02.

## 33.118

## Reagents

- Prep. reagents 33.114(a), (d), and (f), and following:
- (a) *Potassium antimonyl tartrate soln.*—Weigh 0.3 g  $\text{K(SbO)C}_4\text{H}_4\text{O}_6 \cdot 0.5\text{H}_2\text{O}$ , dissolve in ca 50 mL  $\text{H}_2\text{O}$ , and dil. to 100 mL. Store in dark g-s bottle at 4°.
- (b) *Ammonium molybdate soln.*—Dissolve 4 g  $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ . Store in plastic bottle at 4°.
- (c) *Combined reagent*.—Prep. as in 33.114(e). 100 mL is enough for 4 hr operation. Prep. fresh for each series.
- (d) *Wash water*.—Add 40 mL hydrolyzing acid soln, 33.114(f), to ca 1 L  $\text{H}_2\text{O}$  and dil. to 2 L (not used when only orthophosphate is detd).
- (e) *Phosphorus std solns.*—(1) *Stock soln.*—0.1 mg P/L. Dissolve and dil. 0.4393 g  $\text{KH}_2\text{PO}_4$ , dried at 105°, to 1 L. (2) *Intermediate soln 1.*—0.01 mg P/L. Dil. 100 mL stock soln to 1 L. (3) *Intermediate soln 2.*—0.001 mg P/L. Dil. 100 mL intermediate soln 1 to 1 L. (4) *Working solns.*—Dil. 0.0, 2.0, 5.0, and 10.0 mL intermediate soln 2 and 2.0, 5.0, 8.0, and 10.0 mL intermediate soln 1 to 100 mL to prep. std solns contg 0.00, 0.02, 0.05, 0.10, 0.20, 0.50, 0.80, and 1.00 mg P/L, resp.

## 33.119

## Determination

Store and prep. samples as in 33.115.

(a) *Phosphorus*.—Proceed as in 33.115(a), but det. orthophosphate as in (c), below.

(b) *Hydrolyzable phosphorus*.—Proceed as in 33.115(a), omitting addn of  $\text{NH}_4$  persulfate, and det. orthophosphate as in (c), below.

(c) *Orthophosphate*.—Set up manifold as in Fig. 33:02. Let colorimeter and recorder warm up 30 min. Run baseline with all reagents but with  $\text{H}_2\text{O}$  thru sample line. Adjust dark current and operative opening on colorimeter to obtain stable baseline. Place wash  $\text{H}_2\text{O}$ , (d), in sampler in pairs, for other than ortho-P, and  $\text{H}_2\text{O}$  for ortho-P, leaving every third position vacant. Set sample timing at 1 min. Place std solns in sampler in vacant positions in order of decreasing concn and complete filling of sampler tray with unknown samples. Change sample line from  $\text{H}_2\text{O}$  to sampler and begin analysis.

(d) *Std curve and calculation*.—Prep. std curve by plotting peak hts against mg P/L. Obtain sample concn from peak ht. Reanalyze any sample whose computed value is  $< 5\%$  of its immediate predecessor.

## Sulfate

## Turbidimetric Method (1, 2)

## 33.120

## Principle

Sulfate is pptd in dil.  $\text{HCl}$  with  $\text{BaCl}_2$  under controlled conditions to form  $\text{BaSO}_4$  crystals of uniform size. *A* of suspension is measured and sulfate concn is obtained from std curve.

Method is applicable to drinking and surface waters and domestic and industrial wastes. Dil. samples to concn of  $\leq 40$  mg  $\text{SO}_4/\text{L}$ . Color and suspended matter interfere. Some suspended matter is removed by filtration. Remaining interference is corrected by blank which omits  $\text{BaCl}_2$ .

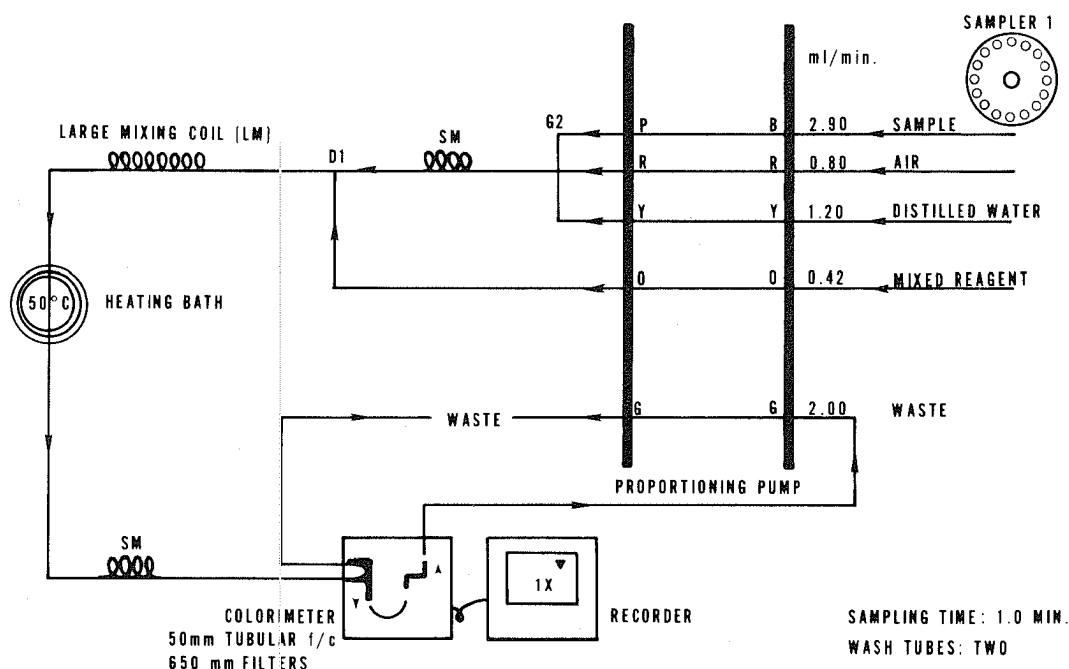

FIG. 33.02—Phosphorus manifold

Synthetic H<sub>2</sub>O samples contg exact increments of inorg. SO<sub>4</sub> analyzed by 34 analysts in 16 laboratories showed following results:

Increment as mg SO <sub>4</sub> /L	Std deviation		Bias	
	%	mg SO <sub>4</sub> /L	%	mg SO <sub>4</sub> /L
8.6	27	2.3	-3.7	-0.3
9.2	20	1.8	-8.3	-0.8
110	7.1	7.9	-3.0	-3.3
122	6.1	7.5	-3.4	-4.1
188	5.1	9.6	0.0	+0.1
199	5.9	11.8	-1.7	-3.4

**33.121****Apparatus**

(a) *Magnetic stirrer*.—Adjustable, but once set must operate at const speed. Stirring bars must be of identical shape and size. Exact speed is not critical, but it should be const for each series of samples and stds and should be at max. at which no splashing occurs. Timing device to permit operation for exactly 1 min is desirable.

(b) *Photometer*.—Nephelometer, spectrophtr set at 420 nm with 4–5 cm cell, or filter photometer with filter having max. *T* near 420 nm with 4–5 cm cell.

**33.122****Reagents**

(a) *Conditioning reagent*.—Mix 50 mL glycerol with soln of 30 mL HCl, 300 mL H<sub>2</sub>O, 100 mL alcohol or isopropanol, and 75 g NaCl.

(b) *Barium chloride*.—Crystals, 20–30 mesh. Dispense from 0.2–0.3 mL measuring spoon.

(c) *Sulfate std soln*.—100 µg SO<sub>4</sub>/mL. Dil. 10.41 mL 0.0200*N* H<sub>2</sub>SO<sub>4</sub> to 100 mL, or dissolve 147.9 mg anhyd. Na<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L.

**33.123****Determination**

Pipet 5 mL conditioning reagent into 100 mL sample or aliquot dild to 100 mL in 250 mL erlenmeyer, and mix on mag. stirrer.

While stirring, add spoonful of BaCl<sub>2</sub> crystals and begin timing. Stir exactly 1 min at const speed. Immediately transfer some soln into cell and measure turbidity at 30 sec intervals for 4 min. Record max. reading. Conduct blank detn without BaCl<sub>2</sub> and subtract reading.

Prep. std curve by carrying 0–40 mg SO<sub>4</sub>/L, in 5 mg increments, thru entire detn. Introduce std soln with every 3–4 samples.

mg SO<sub>4</sub>/L = mg SO<sub>4</sub> from curve × 1000/mL sample.

**33.124 Gravimetric Method**

Make preliminary examination, using 100–250 mL sample, to det. approx. amt of sulfates. (Alkali salts present can be approximated by calcg amt of Na necessary to combine with excess of acids—HCl, H<sub>2</sub>SO<sub>4</sub>, and H<sub>2</sub>CO<sub>3</sub>—over Ca and Mg.)

Take enough sample (usually 1–5 L) to yield ≤1 g BaSO<sub>4</sub> and ≤0.5 g mixed chlorides. Acidify with HCl (1+1), evap. to dryness in Pt dish, and remove SiO<sub>2</sub> by 2 evapns as in 33.077, using ≤2 mL HCl for final soln. Combine filtrate and washings from SiO<sub>2</sub> detns and conc. to 150–200 mL. Heat to bp and ppt with slight excess of 10% BaCl<sub>2</sub>·2H<sub>2</sub>O soln, added very slowly and with const stirring. Cover, and let stand on steam bath ca 12 hr. Filter, thoroly wash BaSO<sub>4</sub> ppt with hot H<sub>2</sub>O until Cl-free, dry, ignite over Bunsen burner and weigh.

If sulfate content of sample is unusually large, proceed as far as concn of SiO<sub>2</sub> filtrates, as above. Add 50 mL HCl, heat to bp, and ppt with BaCl<sub>2</sub> soln as before. Evap. to dryness, take up in H<sub>2</sub>O and few drops HCl, digest until ppt settles, wash by decantation, filter, ignite, and weigh. Calc. to SO<sub>4</sub> ion.

**33.125 Preparation of Sample—Manganese, Iodine, Bromine, Arsenic, and Boric Acid—Official Final Action**

Evap. 0.5–2 L sample to dryness after addn of small amts of solid Na<sub>2</sub>CO<sub>3</sub>. Boil residue thus obtained with H<sub>2</sub>O, transfer to filter, and wash thoroly with hot H<sub>2</sub>O. Use residue remaining on filter for detn of Mn. Dil. alk. filtrate to definite vol. and use for detn of I, Br, As, and H<sub>3</sub>BO<sub>3</sub>.

**Manganese—Official Final Action****Persulfate Method****33.126****Reagents**

(a) *Silver nitrate soln.*—Dissolve 2 g  $\text{AgNO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(b) *Manganese std soln.*—0.1 mg/mL. Dissolve 0.2877 g  $\text{KMnO}_4$  in ca 100 mL  $\text{H}_2\text{O}$ , acidify soln with  $\text{H}_2\text{SO}_4$  (1+1), and slowly heat to bp. Slowly add enough 10%  $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  soln to discharge color. Cool, and dil. to 1 L.

**33.127****Determination**

Dissolve insol. residue, **33.125**, in excess  $\text{HNO}_3$  (1+1), evap. to dryness, treat with  $\text{H}_2\text{O}$ , and add ca 1 mL  $\text{HNO}_3$  and little of the  $\text{AgNO}_3$  soln. If ppt of  $\text{AgCl}$  appears, add addnl  $\text{AgNO}_3$  soln until all  $\text{Cl}$  is pptd. Add excess of ca 10 mL  $\text{AgNO}_3$  soln for each mg  $\text{Mn}$  present in sample. Filter, add 1 g  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  to filtrate, and place beaker or flask contg soln on steam bath until pink color develops (ca 20 min). Compare color developed with stds similarly prepd by treating solns contg known amts of std  $\text{Mn}$  soln with dil.  $\text{HNO}_3$ ,  $\text{AgNO}_3$  soln, and  $(\text{NH}_4)_2\text{S}_2\text{O}_8$ .

**33.128 ★ Bismuthate Method (11) ★**

See 31.037–31.038, 10th ed.

**Iodide and Bromide—Official First Action**

(This method is qual. and approx. quant. For accurate quant. methods for iodides, see **33.149**.)

**33.129****Determination**

(Caution: See 51.039, 51.040, 51.047, and 51.048.)

Evap. aliquot of alk. filtrate, **33.125**, to dryness; add 2–3 mL  $\text{H}_2\text{O}$  to dissolve residue and enough alcohol to make ca 90% alcohol. (This ppts chlorides.) Heat to bp, filter, and repeat soln and pptn once or twice. Add 2 or 3 drops 10%  $\text{NaOH}$  soln to combined alc. filtrates and evap. to dryness. Dissolve last residue in 2–3 mL  $\text{H}_2\text{O}$  and repeat pptn with alcohol, heating, and filtering. Add drop of 10%  $\text{NaOH}$  soln to this alc. filtrate and evap. to dryness.

Dissolve residue in little  $\text{H}_2\text{O}$ , acidify with  $\text{H}_2\text{SO}_4$  (1+5), using 3 or 4 drops excess, and transfer to small flask. Add 4 drops 0.2%  $\text{NaNO}_2$  soln and ca 5 mL  $\text{CS}_2$ . Shake until all  $\text{I}$  is extd and filter off acid soln from  $\text{CS}_2$ . Wash flask, filter, and contents with cold  $\text{H}_2\text{O}$  and transfer  $\text{CS}_2$  contg the  $\text{I}$  in soln to Nessler tube, using ca 5 mL  $\text{CS}_2$ . In washing filter, make contents of tube to definite vol., usually 12–15 mL, and compare color with that of other tubes contg known amts of  $\text{I}$  dissolved in  $\text{CS}_2$ . Prep. these std tubes by treating measured amts of soln of known  $\text{KI}$  content as above, beginning "... acidify with  $\text{H}_2\text{SO}_4$  (1+5), ..."

Sep. transfer acid soln of sample and stds from which  $\text{I}$  has been removed to small flasks. To stds add definite measured amts of bromide soln of known concn, and to each flask contg sample and stds add 5 mL  $\text{CS}_2$ . Add *satd and freshly prepd*  $\text{Cl-H}_2\text{O}$ , 1 mL at time, shaking after each addn until all  $\text{Br}$  is set free. Avoid large excess of  $\text{Cl}$ , as a bromo-chloride may form and change color reaction.

Filter off aq. soln from  $\text{CS}_2$  thru moistened filter, wash contents of filter 2 or 3 times with  $\text{H}_2\text{O}$ , and then transfer to Nessler tube with ca 1 mL  $\text{CS}_2$ . Repeat extn of filtrate twice, using 3 mL  $\text{CS}_2$  each time. Combined  $\text{CS}_2$  exts usually total 11.5–12 mL. Add enough  $\text{CS}_2$  to tubes to make definite vol., usually 12–15 mL, and compare sample with stds. If, when using this method near

its upper limit, amts of  $\text{CS}_2$  recommended do not ext all  $\text{Br}$ , make 1 or 2 addnl extns with  $\text{CS}_2$ , transfer exts to another tube, and compare color with some of lower stds. Add readings thus obtained to others.

Results closely approximating true values for  $\text{I}$  and  $\text{Br}$  can be obtained in shorter time on most samples by omitting extns with alcohol and comparing color of  $\text{CS}_2$  solns directly in extn flasks.

**33.130 ★ Bromide in Presence of Chloride but not Iodide (72)—Official First Action**

See 31.040–31.043, 10th ed.

**33.131 ★ Bromide in Presence of Chloride and Iodide (13)—Official Final Action**

See 31.044–31.046, 10th ed.

**Arsenic—Official Final Action****33.132****Reagents and Apparatus**

See 25.006 and 25.007.

**33.133****Determination**

Take portion of alk. filtrate, **33.125**, contg  $\leq 0.03$  mg  $\text{As}_2\text{O}_3$ . If amt taken is  $> 10$  mL, evap. soln to ca that vol. on steam bath. Transfer soln into generator of app., **25.007**, with aid of ca 10 mL  $\text{H}_2\text{O}$ , add 20 mL  $\text{H}_2\text{SO}_4$  (1+2), and proceed as in **25.010** or **25.012**, beginning with addn of  $\text{KI}$  reagent.

**★ Boric Acid ★****33.134 Qualitative Test—Procedure**

See 31.049, 10th ed.

**33.135 Quantitative Method (14)—Official First Action**

Titrn with  $\text{NaOH}$  in presence of mannitol. See 31.050–31.051, 10th ed.

**33.136 Lead**

See 25.095–25.100.

**33.137 Method of Reporting Results (75)—Procedure**

Report radicals and anhyd. salts in mg/L or, in case of highly concd waters, in g/L. For benefit of physicians, in case of medicinal waters, also report salts in terms of grains/qt, using factor 0.014600 to convert mg/L to grains/qt. In reporting salts in terms of grains/qt, convert salts that have  $\text{H}_2\text{O}$  of crystn to hydrated form as expressed in USP and in NF, and convert  $\text{Mg}(\text{HCO}_3)_2$  to  $\text{MgCO}_3$  and  $\text{Ca}(\text{HCO}_3)_2$  to  $\text{CaCO}_3$ . Use following factors in these calcns:

When complete analysis is made, report error of analysis and state how it is distributed. Report only significant figures.

Report  $\text{Fe}$  and  $\text{Al}$  together when present in unimportant amts and in calcns consider them as  $\text{Fe}$ . When  $\text{Fe}$  and  $\text{Al}$  are present in larger amts, make sepn and report each sep.

In calcg hypothetical combinations of anions and cations, join  $\text{NO}_2$ ,  $\text{NO}_3$ ,  $\text{BO}_3$ , and  $\text{AsO}_4$  to  $\text{Na}$ ;  $\text{I}$  and  $\text{Br}$  to  $\text{K}$ ; and  $\text{PO}_4$  to  $\text{Ca}$ . Assign residual cations in following order:  $\text{NH}_4$ ,  $\text{Li}$ ,  $\text{K}$ ,  $\text{Na}$ ,  $\text{Mg}$ ,

★ Surplus method—see inside front cover.

in following order: Cl,  $\text{ICO}_3$  is present to join, to form  $\text{CaSiO}_3$ , and  $\text{Fe}_2\text{O}_3$ , and  $\text{Al}_2\text{O}_3$ , resp. reciprocals in uniting se of comparison, in calcs in order specified

ed by dividing its wt salt is obtained by f basic element and alt.

ions by use of equiv. follows:

or, for highly concd d, by corresponding d K are to be detd act sum of values om sum of reacting s reacting value of

en detd, sums of uld be very nearly

equal. In this case, if difference is reasonable and well within limit of accuracy of methods used, it may be distributed equally among all radicals detd, or among those believed to be less accurately detd than others. If difference is unreasonably great, repeat analysis in whole or in part. Sums of reacting values of acid and basic radicals must be equal before calcn is made. Obtain reacting values of the salts by subtracting in succession reacting values of radicals in specified order. To convert these values to mg/L of respective salts, multiply each of them by the equiv. combining wt of respective salt.

### SALT (16)

#### 33.138 Preparation of Sample—Procedure

If sample is coarser than "20 mesh," grind so that all will pass No. 20 sieve, but avoid undue grinding so that as much as possible will be retained on No. 80 sieve. Mix sample by quartering and weigh all needed portions as nearly at same time as possible.

#### 33.139 Moisture—Official First Action

Place ca 10 g sample in dry, weighed 200 mL erlenmeyer. Weigh flask and sample. Spread sample evenly over bottom of

flask by shaking gently and insert small funnel in neck. Heat flask and sample for periods of 1 hr each at ca 250° until 2 consecutive weighings agree within 5 mg. Occasionally shake flask so that sample will dry evenly. Report loss of wt as H<sub>2</sub>O.

### 33.140 Matters Insoluble in Water—Official First Action

Place 10 g sample in 250 mL beaker, add 200 mL H<sub>2</sub>O at room temp., and let stand 30 min, stirring frequently. Filter thru weighed gooch with asbestos mat dried at 110°. Transfer residue to gooch with aid of policeman, using total of ≤50 mL H<sub>2</sub>O. Wash residue with ca ten 10 mL portions H<sub>2</sub>O, until 10 mL filtrate shows only faint opalescence upon addn of few drops AgNO<sub>3</sub> soln. Dry crucible and contents to const wt at 110°. Report increase in wt gooch as "matters insol. in H<sub>2</sub>O" and report results in % on H<sub>2</sub>O-free basis. If matters insol. in H<sub>2</sub>O are >0.1%, det. their nature.

### 33.141 Matters Insoluble in Acid (17) Official First Action

Treat 10 g sample with 200 mL HCl (1+19), boil 2–3 min, and let stand 30 min, stirring frequently. Filter thru gooch with mat dried at 110°. Wash, dry at 110°, cool, and weigh. Express results in %.

### 33.142 Preparation of Solution for Sulfate, Calcium, and Magnesium—Procedure

Weigh ca 20 g sample, transfer to 400 mL beaker, and dissolve in 200 mL HCl (1+3). Cover beaker, heat to bp, and continue boiling gently 10 min. Filter thru paper and wash residue with small amts of hot H<sub>2</sub>O until filtrate is Cl-free. Unite filtrate and washings, cool, and dil. to 500 mL (*Soln X*).

### 33.143 Sulfate—Official First Action

Place 250 mL *Soln X*, 33.142, in 400 mL beaker, heat to bp, and add slight excess hot 10% BaCl<sub>2</sub> soln dropwise while stirring. Conc. by heating gently and finally evap. to dryness on steam bath. Facilitate removal of free acid by stirring partly dried residue. Wash ppt by decantation with small amts of hot H<sub>2</sub>O, finally transferring ppt to close-grain filter paper with aid of policeman and stream of hot H<sub>2</sub>O. Test filtrate for presence of Ba. Wash ppt on paper until filtrate is Cl-free. Dry and ignite paper contg ppt over Bunsen flame. Report % SO<sub>4</sub> in sample on H<sub>2</sub>O-free basis.

### 33.144 Calcium—Official First Action

Place remainder of *Soln X* in 400 mL beaker. Add excess of 10% H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O soln (10 mL usually is enough). Add few drops Me orange; neutze while hot by adding NH<sub>4</sub>OH dropwise, stirring constantly. Add ca 1 mL excess NH<sub>4</sub>OH, stir, and let stand in warm place 3 hr. Decant supernate thru filter, reserving filtrate for detn of Mg. Test filtrate for Ca with (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln. Wash ppt in beaker once with 10 mL 1% (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln, decanting thru filter paper. Combine filtrate and washings. Dissolve ppt on paper with hot HCl (1+1), using same beaker; dil. to 100 mL, add little more H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln, and ppt as before. Let stand 3 hr, filter, and wash with 1% (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> soln as before, reserving filtrate and washings. Transfer ppt to crucible, dry, ignite, and heat over blast lamp to const wt (CaO). Report as % Ca on H<sub>2</sub>O-free basis.

### 33.145 Magnesium—Official First Action

Combine filtrates and washings from Ca detn, conc. if necessary by boiling gently to ca 150 mL, and proceed as in 33.088. Report as % Mg on H<sub>2</sub>O-free basis.

### 33.146 Lead

See 25.095–25.100.

### Iodine in Iodized Salt (18)—Official Final Action

#### 33.147

#### Reagents

(a) *Bromine water*.—(Caution: See 51.047.) For alternative method, 33.149(b), det. approx. concn (mg Br/mL) by adding measured vol. from buret to flask contg 50 mL H<sub>2</sub>O, 5 mL 10% KI soln, and 5 mL H<sub>2</sub>SO<sub>4</sub> (1+9), and titrg liberated I with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

(b) *Sodium thiosulfate*.—0.005*N*. Prep. daily by dilg 0.1*N* soln, 50.037–50.038.

(c) *Starch soln*.—1% (freshly prepd). See 2.144(b).

(d) *Potassium iodide control soln*.—0.3270 g KI/250 mL. Dil. 50 mL to 250 mL, and use 5 mL (= 1.0 mg I and 1.308 mg KI) for control.

#### 33.148

#### Preparation of Sample

Dissolve 50 g sample in H<sub>2</sub>O and dil. to 250 mL in vol. flask. Take 25, for 33.149(a), or 50 mL, for 33.149(b), aliquot for analysis.

#### 33.149

#### Determination

(a) *Application when Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> content is ≤0.5%.*—Place sample aliquot in 600 mL beaker and dil. to ca 300 mL. Neutze to Me orange with H<sub>3</sub>PO<sub>4</sub> and add 1 mL excess. Proceed as in 7.115, third par.

(b) *Alternative method. Not applicable in presence of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.*—Pipet 50 mL sample soln into 200 mL erlenmeyer. Neutze to Me orange with 2*N* H<sub>2</sub>SO<sub>4</sub>. Add Br-H<sub>2</sub>O dropwise from buret in amt equiv. to 20 mg Br. After few min destroy greater portion of remaining free Br by adding 1% Na<sub>2</sub>SO<sub>3</sub> soln dropwise while mixing. Wash down neck and sides of flask with H<sub>2</sub>O and complete removal of Br by adding 1 or 2 drops 5% phenol soln. Add 1 mL 2*N* H<sub>2</sub>SO<sub>4</sub> and 5 mL 10% KI soln, and titr. liberated I with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln, adding 1 mL starch indicator near end of titrn. Correct detn for blank on reagents and make 1 or more control detns, using 50 mL 20% reagent grade NaCl soln to which has been added appropriate amts of dil. control KI soln. 1 mL 0.005*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 0.1058 mg I and 0.1384 mg KI.

### 33.150 Method of Reporting Results—Procedure

(In absence of added drying agents such as MgCO<sub>3</sub>, Ca phosphate, etc.)

Convert sulfate to CaSO<sub>4</sub> and unused Ca to CaCl<sub>2</sub>, unless sulfate in sample exceeds amt necessary to combine with Ca, in which case convert Ca to CaSO<sub>4</sub> and unused sulfate first to MgSO<sub>4</sub> and remaining sulfate, if any, to Na<sub>2</sub>SO<sub>4</sub>. Convert unused Mg to MgCl<sub>2</sub>. Add percentages of CaCl<sub>2</sub> and MgCl<sub>2</sub>. Report on H<sub>2</sub>O-free basis % of matter insol. in H<sub>2</sub>O, of SO<sub>4</sub>, of Ca, of Mg, of CaSO<sub>4</sub>, of CaCl<sub>2</sub>, and of MgCl<sub>2</sub>. Also report results of qual. examination of matters insol. in H<sub>2</sub>O, if amt is >0.1% on H<sub>2</sub>O-free basis.

## 34. Color Additives

(Number in brackets following name of a color represents number of that color as listed in Society of Dyers and Colourists' "Colour Index," third edition, 1971.)

In conformity with common usage, thruout this chapter the reagent designated as "amyl alcohol" is actually "isoamyl alcohol.")

#### 34.004 ★ Water-Soluble Dyes (7) ★ Official Final Action

Immiscible solv. method. See 34.004–34.006, 11th ed.

#### SYNTHETIC ORGANIC COLOR ADDITIVES IN FOODS (3)

(Amaranth\*, ponceau 3R\*, ponceau SX\*, erythrosine, orange I\*, light green SF yellowish\*, fast green FCF, guinea green B\*, brilliant blue FCF, indigotine, naphthol yellow S\*, sunset yellow FCF, tartrazine, yellow AB\*, yellow OB\*, orange SS\*, and oil red XO\*.)

#### 34.005 ★ Immiscible Solvent Method ★ Official First Action

See 34.007–34.008, 11th ed.

#### Chromatographic Method

#### 34.006 Identification—Procedure

(a) *Oil-soluble dyes.*—Prep. soln of the isolated dye of suitable concn in  $\text{CHCl}_3$ . Det. spectrophtric curve of this soln and compare curve with those of known dyes in  $\text{CHCl}_3$  solns detd on same instrument under same conditions. If spectrophtric data cannot be correlated with that of known color, unknown color may be mixt. In such cases, proceed as in 34.009–34.013.

(b) *Water-soluble dyes.*—Prep. ca neut. soln of the dye in concn suitable for spectrophtric analysis with cells and instruments available. Divide soln into 3 portions and to 1 portion add few crystals of  $\text{NH}_4\text{OAc}$ . To second portion add  $\text{HCl}$  to make ca 0.1*N*. To third portion add  $\text{NaOH}$  soln to make ca 0.1*N*. Det. spectrophtric curves of the 3 solns and compare with corresponding curves of known dyes detd under same conditions on same instrument.

If spectrophtric data of unknown color cannot be correlated with that of a known color, unknown color may be mixt. In such cases subject unknown color soln to chromatgy. For oil-sol. colors, paper chromatgc procedure of JAOAC 35, 423(1952); 36, 802(1953), or following column chromatgc method may be used.

\* No longer permitted in United States.

★ Surplus method—see inside front cover.

#### 34.007

#### Preparation of Column

Lightly tamp glass wool plug into constricted end of chromatgc tube ca 100 cm long  $\times$  2.54 cm diam. Prep. thin aq. slurry of ca 40 g *powd cellulose*, such as SolkaFloc BW 40 (Brown Co., Berlin, NH 03570), and pour into column. Let liq. drain as cellulose settles and add more slurry as needed until all is added. When liq. level drops almost to top of adsorbent bed, add wash of 20%  $\text{NaCl}$  soln. Just before last of this soln enters adsorbent, close constricted end of column. Column may be used immediately or may be stored for several weeks before use. (Column described is adequate for 0.5–2.0 mg total dye. Column size may be varied if more or less dye is present.)

#### 34.008

#### Chromatographic Separation

To neut. aq. soln of the color add enough  $\text{NaCl}$  to make 20% soln. Pour soln into column so that adsorbent bed is not disturbed; then open constricted end of tube. When last of soln is ready to pass into adsorbent bed, add few mL 20%  $\text{NaCl}$  soln. If any color moves down column at moderate rate, continue washing with 20%  $\text{NaCl}$  soln. If all color remains at or near top of column, change to 10%  $\text{NaCl}$  soln. If this soln fails to move any color down column, change to 5%  $\text{NaCl}$  soln. Continue lowering  $\text{NaCl}$  concn by half until concn is found which moves color down column at moderate rate.

Continue adding appropriate concn of  $\text{NaCl}$  soln until color is eluted and collected. If color seps into 2 or more bands as it progresses down column, collect each band sep. In some cases it may be necessary to change to still more dil.  $\text{NaCl}$  soln to elute upper bands of color. If  $\geq 2$  bands of color are found, examine each spectrophtric as in 34.006(b). If this procedure gives no indication that  $>1$  color is present, it may be assumed that color is not mixt.

#### Chromatographic Separation of Oil-Soluble Color Additives (4)—Official First Action

#### 34.009

#### Principle

Eleven oil-sol. color additives are sepd chromatgc. Colors in fractions are identified spectrophtric. Steps are given in Table 34:01.

#### 34.010

#### Apparatus

*Chromatographic tubes.*—20 (id)  $\times$  300 mm, with stopcock and fritted glass plate (or glass fiber disk over glass wool plug). With device to deliver air pressure at top.

#### 34.011

#### Reagents

(a) *Florisil.*—60–100 mesh. Activated at 650° (1200°F) by manufacturer (Floridin Co). Store at 130° in g-s bottle. For use, add 1.5 mL  $\text{H}_2\text{O}$  to 100 g Florisil in g-s bottle, shake to break up lumps, and mix thoroly. Let stand overnight before use.

(b) *Alumina.*—80–200 mesh. Adsorption, for chromatgc analysis. Heat 100–200 g 1 hr at 400°. Store in tightly stoppered bottle in desiccator.

(c) *Adsorptive magnesia.*—Fisher Scientific Co. No. S-120.

(d) *Celite 545.*—Johns-Manville Products Corp.

(e) *Silicic acid.*—100 mesh. For chromatgy (Mallinckrodt Chemical Co. No. 2847, or equiv.).

(f) *Solvents.*—Reagent grade. Pet ether, ether, alcohol,  $\text{CHCl}_3$ , *n*-hexane, benzene, and  $\text{CH}_3\text{CN}$ . Redistil  $\text{CH}_3\text{CN}$  from  $\text{H}_3\text{PO}_4$  and  $\text{P}_2\text{O}_5$ , if necessary.

\* No longer permitted in the United States.

## ANALYSIS OF COMMERCIAL SYNTHETIC ORGANIC COLOR ADDITIVES

### 34.015 Specifications for Certifiable Synthetic Organic Color Additives

Color Additive Amendment of 1960 to Federal Food, Drug, and Cosmetic Act provides for listing of color additives that are safe for use in foods, drugs, or cosmetics, and for certification of batches of those colors. "Code of Federal Regulations," Title

21, Part 74 provides listings of such color additives; provisionally listed colors are found in Part 81. Colors must be free from impurities to extent avoidable by good manufacturing practice. Color certification examines each batch for color content, subsidiary colors, intermediates, heavy metals, volatile matter, and inorg. salts.

Methods no longer used and colors and their specifications applicable to colors previously certifiable will be found in 9th, 10th, 11th, and 12th eds of *Official Methods of Analysis*. (See also Tables (e), (f), (g), and (h) below.)

**34.016 Preparation of Sample—Official Final Action**

Thoroughly mix and promptly weigh portion required. If weighing cannot be made directly into dish in which detn is to be made, use weighing bottles, placing in each bottle amt approximating wt required, and weighing immediately.

**Pure Dye****By Titration with Standard Titanous Chloride Solution—Official Final Action****34.017****Apparatus**

See Fig. 34:01.

**34.018****Reagents**

(a) *Titanous chloride std soln.*—0.1*N*. See 50.042–50.043. See Tables 34:02 and 34:03 for factors.

(b) *Potassium dichromate std soln.*—See 50.024.

(c) *Indicator.*—For many dyes  $\text{TiCl}_3$  titrn end point is indicated by sharp decoloration. For some dyes change is so gradual that excess of  $\text{TiCl}_3$  ( $\leq 0.3$  mL ca 0.1*N* soln) is required, and suitable std soln of some other dye must be used for back-titrn (methylene blue serves well). In other cases it is better to use indicator that is reduced after original dye has reacted with the  $\text{TiCl}_3$ . Known amt of FD&C Green No. 2 serves well for this purpose.

**34.019****Determination**

(a) Prep. 1.0% soln of sample in  $\text{H}_2\text{O}$  and place vol. soln equiv. to ca 20 mL 0.1*N*  $\text{TiCl}_3$  in 500 mL wide-mouth erlenmeyer. Add 15 g Na citrate and  $\text{H}_2\text{O}$  to bring vol. to 150–200 mL. Heat to bp and titr. with std  $\text{TiCl}_3$  soln.

(b) Prep. 0.5% soln of sample in alcohol. Proceed as in (a), substituting 50% alcohol for  $\text{H}_2\text{O}$ .

(c) Proceed as in (a), substituting 15 g Na acid tartrate for Na citrate.

(d) Proceed as in (c), using as indicator vol. FD&C Green No. 2 soln (freshly prepd) contg ca 10 mg dye. Det.  $\text{TiCl}_3$  soln equiv. to vol. indicator soln used and deduct this vol. from total required for titrn.

(e) Prep. 0.5% soln of sample in alcohol. Proceed as in (d), substituting 50% alcohol for  $\text{H}_2\text{O}$ .

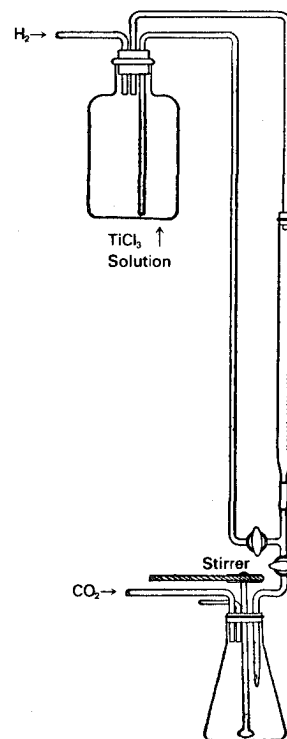

FIG. 34:01—Titanous chloride titration apparatus

(f) (JAOAC 24, 904(1941); 32, 644(1949)). In wide-mouth erlenmeyer dissolve 0.2 g sample in 5 mL  $\text{H}_2\text{SO}_4$ , using stirring rod to break up any lumps, and mix well. Dil. with 100 mL alcohol and heat, with stirring, until all dye is in soln. Dissolve 20 g Na acid tartrate in 100 mL boiling  $\text{H}_2\text{O}$  and add 20 mL 30% NaOH soln. Stirring rapidly, add this soln to alc. dye soln. Titr. resulting soln with std  $\text{TiCl}_3$  soln.

(g) Place sample equiv. to ca 20 mL 0.1N  $\text{TiCl}_3$  in 50 mL beaker, and pour 2 mL fuming  $\text{H}_2\text{SO}_4$  (20% free  $\text{SO}_3$ ) down side of beaker. Stir well with glass rod and place on steam bath. After 30 min pour sulfonated product into 500 mL wide-mouth erlenmeyer contg 100 g ice. Add few g cracked ice to material remaining in beaker and wash all color into flask. Add 50 mL alcohol and 20 g Na acid tartrate, heat, and titr. in usual manner.

(h) Proceed as in (g), but sulfonate at room temp.

**Table 34:03 Conversion Factors—Precipitated Color Acids to Specified Salts**

Color	Factor
FD&C Red No. 3	1.074 <sup>a</sup>
D&C Red No. 22	1.068
D&C Red No. 28	1.056
D&C Orange No. 11	1.075

<sup>a</sup> Includes 1 molecule  $\text{H}_2\text{O}$  of crystn.

#### 34.020 Gravimetrically—Official Final Action

(a) Prep. 1.0% soln of sample in  $\text{H}_2\text{O}$ . Transfer 50 mL aliquot to 500 mL beaker, heat to bp, add 25 mL HCl (1+49), and again bring to bp. Wash down sides of beaker with little  $\text{H}_2\text{O}$ , cover with watch glass, and keep on steam bath several hr or overnight. Cool to room temp., transfer ppt to weighed gooch with HCl

(1+199), and wash with two 10–15 mL portions  $\text{H}_2\text{O}$ . Dry crucible and ppt 3 hr at 135°, cool in desiccator, and weigh.

% Pure dye = wt ppt  $\times$  conversion factor

(Table 34:03)  $\times$  100/wt sample

(b) Prep. 1.0% soln of sample in ca 0.1N NaOH and proceed as in (a). No factor is required since colors for which this method is specified are not salts.

#### ★ From Nitrogen Content—Official Final Action ★

##### 34.021 Micro-Kjeldahl Method

See 34.027–34.029, 11th ed.

#### ★ From Sulfur Content ★

##### 34.022 Fusion Method—Official Final Action

See 34.030, 11th ed.

##### 34.023 Perchloric Acid Digestion Method (5) Official First Action

See 34.031–34.032, 11th ed.

#### By Spectrophotometric Measurement (6) Official Final Action

##### 34.024 Apparatus

(a) *Spectrophotometer*.—Capable of accurate measurement of solns in region 400–750 nm; preferably with effective slit width of  $\leq 10$  nm.

(b) *Two or more matched absorption cells*.

##### 34.025 Reagents

(a) *Std sample of dye to be determined*.—Std samples should be carefully prepd and of highest attainable purity. Pure dye content of std samples must be accurately known for quant. results.

(b) *Solvents*.—Free from suspended matter.

##### 34.026 Standardization

Prep. series of solns of known concns of std sample and det.  $A (= \log (1/T))$  of solns, corrected for  $A$  due to solv. and cell, at suitable wavelength. (Wavelength at which  $A$  is max. is usually selected.) Adjust concns of solns to give  $A$  values of 0.4–1.0 with instrument and cells used. Plot or tabulate data obtained.

##### 34.027 Determination

Prep. sample soln in solv. used in stdzn. (Soln must be of such concn that  $A$  obtained will be in range covered by stds examined.) Det.  $A$  of this soln under same conditions used in stdzn.

Calc. "pure dye" content of sample from  $A$  of sample soln and  $A'$  of std soln:

Pure dye =  $(A/\text{concn sample})(\text{concn std}/A') \times \text{purity of std.}$

If straight line does not result when  $A'$  and concn data obtained from examination of std soln are plotted, i.e., if Beer's law does not hold, det. concn of "unknown" soln by comparison with data obtained from known soln of very nearly same concn.

##### 34.028 Volatile Matter—Official Final Action

Accurately weigh ca 2 g sample into tared weighing bottle ca 4 cm diam., and dry in air oven at temp. prescribed, 34.015, 6 hr or overnight. Cool over efficient desiccant and reweigh. Report loss in wt as volatile matter.

★ Surplus method—see inside front cover.

## INSOLUBLE MATTER

## 34.029 Water-Insoluble Matter—Official Final Action

Dissolve 2 g sample in 200 mL hot H<sub>2</sub>O and let soln cool to room temp. Filter thru gooch, fitted with glass fiber disk, dried at 135°, and weighed. Wash with cold H<sub>2</sub>O until washings are colorless, dry 3 hr at 135°, cool in desiccator, and weigh. Report increase in wt as H<sub>2</sub>O-insol. matter.

34.030 Carbon Tetrachloride-Insoluble Matter  
Official Final Action

(Caution: See 51.040 and 51.049.)

Mix 0.2–0.5 g sample with 100 mL CCl<sub>4</sub> in 250 mL beaker, stir, and heat to bp. Filter hot soln thru weighed gooch, transfer residue in beaker to filter, and wash with 10 mL portions CCl<sub>4</sub> until washings are colorless. Dry 3 hr at 100–105° and weigh. Report increase in wt as CCl<sub>4</sub>-insol. matter.

## 34.031 Toluene-Insoluble Matter—Official Final Action

Proceed as in 34.030, but substitute toluene for CCl<sub>4</sub>.

## 34.032 Benzene-Insoluble Matter—Official Final Action

(Caution: See 51.039, 51.040, and 51.045.)

Proceed as in 34.030, but substitute benzene for CCl<sub>4</sub>.

## 34.033 Acetone-Insoluble Matter—Official First Action

Proceed as in 34.030, but substitute acetone for CCl<sub>4</sub>.

## 34.034 Alcohol-Insoluble Matter—Official First Action

Proceed as in 34.030, but substitute alcohol for CCl<sub>4</sub>.

34.035 ★ Carbon Tetrachloride—Insoluble Matter ★  
Official First Action

See 34.046, 11th ed.

## 34.036 Xylene-Insoluble Matter—Official First Action

Proceed as in 34.030, but substitute xylene for CCl<sub>4</sub>.

34.037 Insoluble Matter (Alkaline Solution)  
Official First Action

Proceed as in 34.029, but use 1% NaOH soln or NH<sub>4</sub>OH (1+14) instead of H<sub>2</sub>O.

Intermediates in FD&C Blue No. 1 (10)  
Official Final Action

## 34.046

## Principle

FD&C Blue No. 1 (C.I. No. 42090) is more strongly adsorbed on cellulose from concd (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> soln than are dye intermediates. Benzaldehyde sulfonic acids (SB), i.e., composite of *ortho* (OSB), *meta* (MSB), and *para* (PSB) isomers, and *N*-ethyl-*N*-(3-sulfobenzyl) sulfanilic acid (ESBSA) can be estd from UV absorption spectra of eluate fractions between 350 and 230 nm.

## 34.047

## Apparatus

(a) *Chromatographic tube*.—400 mm long × 24 mm id with sealed-in coarse fritted disk. Attach short length of clean, rubber tube with pinchcock.

(b) *Spectrophotometer*.—Suitable for use in quartz UV region. (Recording spectrophtr is preferred.)

## 34.048

## Reagents

(a) *Eluent*.—Dissolve 400 g (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in H<sub>2</sub>O and dil. to 1 L. Eluant should be free of Fe and other UV absorbing impurities. Test for purity as follows: Slurry eluant with 1/5 its wt of cellulose powder and filter. A should be ≤0.08 in the 350–230 nm region when measured in 1 cm cell against H<sub>2</sub>O.

(b) *Cellulose powder*.—Whatman "Ashless Powder Chemically Prepared, Standard Grade," or equiv.

(c) *Ammonium sulfate*.—Grind to fine powder.

## 34.049

## Preparation of Chromatographic Column

Slurry 24 g cellulose powder in 140 mL eluant. Close pinchcock and pour slurry into tube. Open pinchcock and let eluate drain at ≤5 mL/min until liq. is only 1–2 mm above level of packed cellulose. Close cock.

## 34.050

## Separation of Intermediates

Place 0.200 g sample in 50 mL beaker. Add 10 mL H<sub>2</sub>O and stir to dissolve. Add 2 g cellulose powder and mix. Add 7 g (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> powder and mix well. Transfer mixt. to top of prepd column. Rinse beaker with 5 mL eluant and add washings to column. Let column drain until flow nearly ceases. Add eluant to column and adjust flow rate to ≤5 mL/min. Immediately collect 10.0±0.05 mL fractions. Collect as many 10.0 mL fractions as necessary to remove compds from column; 30 fractions should be enough, but exact number can be detd by inspection of fractions. Record spectra from 350 to 230 nm against eluant in 1.00 cm fused silica absorption cells, dilg fractions with eluant if necessary.

★ Surplus method—see inside front cover.

## 34.051

## Calculations

Examine spectra to det. compds present. Calc. to nearest 0.01%, with min. report of "<0.05%."

OSB, MSB, and PSB elute together and generally appear between fractions 7 and 15 with absorption max. near 252, 246, and 251 nm, resp. Calc. as SB at 252 nm, i.e., isoabsorptive point of OSB and MSB.

If *o*-chlorobenzoic acid and/or *o*-sulfobenzoic acid are present in sample, they will be eluted just ahead of SB; sepn may not be complete. Benzoic acids are identified by small max. or shoulders near 270 nm, but are not estd by this method. To calc. fraction as SB, ratio  $A_{252}/A_{274}$  must be  $\geq 2.0$ .

ESBSA generally appears between fractions 15 and 30 and has absorption max. near 274 nm.

Any fraction whose absorption cannot be attributed to above compds should be noted and  $A$  at peak reported.

% SB =  $0.0969 \times \Sigma A_{252}$ , where  $\Sigma A_{252}$  = sum of  $A$  (corrected for diln if dild) of all fractions contg SB; and  $0.0969 = 100/(51.6 \times 20.0 \times 1)$ , where 100 = factor for conversion to %, 51.6 =  $A$  at 252 nm of mixt. of 92% (OSB + MSB) + 8% PSB, 20.0 = effective sample concn in g/L, and 1 = path length in cm.

% ESBSA =  $0.0806 \times \Sigma A_{274}$ , where  $\Sigma A_{274}$  = sum of  $A$  of all fractions contg ESBSA; and  $0.0806 = 100/(62.0 \times 20.0 \times 1)$ , where 100 = factor for conversion to %, 62.0 = ESBSA  $A$  at 274 nm, 20.0 = effective sample concn in g/L, and 1 = path length in cm.

% Other absorbers =  $0.10 \times \Sigma A_x$ , where  $\Sigma A_x$  = sum of  $A$  at wavelength max. of detected absorber; and  $0.10 = 100/(50 \times 20.0 \times 1)$ , where 100 = factor for conversion to %, 50 = assumed  $a$ , 20.0 = effective sample concn in g/L, and 1 = path length in cm.

**34.052 ★ Lake Red C Amine in D&C Red Nos. 8 ★ and 9 (17)—Official Final Action**

See 34.065–34.066, 11th ed.

**Intermediates in FD&C Yellow No. 6 (12)  
Official First Action**

## 34.053

## Principle

FD&C Yellow No. 6 (C.I. No. 15985) is more strongly adsorbed on cellulose from concd  $(\text{NH}_4)_2\text{SO}_4$  soln than are dye intermediates. Sulfanilic acid and Schaeffer's salt elute sep. with 40%  $(\text{NH}_4)_2\text{SO}_4$ ; 6,6'-oxybis(2-naphthalenesulfonic acid) (DONS) elutes with 20%  $(\text{NH}_4)_2\text{SO}_4$ . Each intermediate is detd by UV spectrophotometry.

## 34.054

## Apparatus

(a) *Chromatographic tube*.—Approx. 20 (id)  $\times$  400 mm with sealed-in coarse fritted disk (Corning No. 38450, or equiv.). Attach short length of clean rubber tube with pinchcock.

(b) *Spectrophotometer*.—See 34.047(b); with 5 cm cells.

## 34.055

## Reagents

(All reagents must be free of UV-absorbing impurities. Test for purity as follows: Conduct blank as in detn.  $A$  of each fraction should be  $\leq 0.4$  in 210–370 nm region in 5 cm cell against  $\text{H}_2\text{O}$ .)

(a) *Ammonium sulfate solns*.—(1) 40%.—Dissolve 400 g in  $\text{H}_2\text{O}$  and dil. to 1 L in vol. flask. (2) 20%.—Dissolve 400 g in  $\text{H}_2\text{O}$  and dil. to 2 L in vol. flask.

(b) *Cellulose powder*.—Whatman CF 11, or equiv.

## 34.056

## Preparation of Chromatographic Column

Slurry 30 g cellulose powder in 200 mL 40%  $(\text{NH}_4)_2\text{SO}_4$  soln. With pinchcock open, pour slurry into tube and let eluant drain to surface of cellulose. Wash column with 200 mL same eluant, let drain until liq. is 1–2 mm above level of packed cellulose, and close pinchcock.

## 34.057

## Separation of Intermediates

Place 0.500 g sample in 100 mL vol. flask. Dissolve in  $\text{H}_2\text{O}$ , dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 5 mL into 50 mL beaker. Add 2 g cellulose powder and mix. Add 7 g  $(\text{NH}_4)_2\text{SO}_4$  powder and mix. Transfer quant. to tube, using ca 5 mL 40%  $(\text{NH}_4)_2\text{SO}_4$  soln, and let drain just to surface of cellulose. Open pinchcock, add 250 mL 40%  $(\text{NH}_4)_2\text{SO}_4$ , and immediately begin collecting  $50 \pm 1$  mL fractions. After eluant has just passed into column, elute with 20%  $(\text{NH}_4)_2\text{SO}_4$  and collect 50 mL fractions until color elutes (ca 1 L).

Record spectra in 5 cm cells from 370 to 210 nm against 40%  $(\text{NH}_4)_2\text{SO}_4$  soln for fractions 1–8 and 20%  $(\text{NH}_4)_2\text{SO}_4$  soln for remaining fractions, dilg with respective eluant, if necessary.

## 34.058

## Calculations

Examine spectra to det. compds present. Calc. to nearest 0.01%, with min. report of "<0.02%."

Sulfanilic acid normally elutes in fractions 3–6; Schaeffer's salt in fractions 8–10; and DONS in fractions 16–23.

% Sulfanilic acid (as Na salt, MW 195.2)  
=  $0.496 \times \Sigma[(A_1 - A_2)_{250} - (A_3 - A_4)_{360}]$

% Schaeffer's salt (as Na salt, MW 246.2)  
=  $0.131 \times \Sigma[(A_1 - A_2)_{232} - (A_3 - A_4)_{360}]$

% DONS (as di-Na salt, MW 474.4)  
=  $0.234 \times \Sigma[(A_1 - A_2)_{240} - (A_4)_{360}]$ ,

where  $\Sigma[(A_1 - A_2) - (A_3 - A_4)]$  = sums of  $A$  of eluates ( $A_1, A_3$ ) at indicated wavelengths, corrected for solv. blanks ( $A_2, A_4$ ), if necessary, of all fractions contg the appropriate compd;  $0.496 = 100/(80.7 \times 5 \times 0.5)$ ,  $0.131 = 100/(305 \times 5 \times 0.5)$ , and  $0.234 = 100/(171 \times 5 \times 0.5)$ , where 100 = factor for conversion to %, 0.5 = effective sample concn in g/L, 5 = path length in cm, and 80.7, 305, and 171 =  $a$  (L/g-cm) of sulfanilic acid, Schaeffer's salt, and DONS, resp.

**4,4'-(Diazoamino)dibenzene-sulfonic Acid  
(DAADBSA) in FD&C Yellow No. 6**

**High Pressure Liquid Chromatographic Method (13)  
Official First Action**

## 34.059

## Apparatus and Reagents

(a) *Liquid chromatograph*.—DuPont Model 830 with gradient elution accessory and Model 835 multiwavelength detector with 365 nm filter (No. 835052907), or equiv. system. Operating conditions: chart speed, 0.5"/min; eluant flow rate, 1.00 mL/min; detector sensitivity, 0.02  $A$  unit full scale (AUFS); temp., ambient; gradient, 0–100% secondary eluant run in nonlinear, slow start mode (function 4, clockwise) at 1%/min; injection vol., 5  $\mu\text{L}$ . Since peak size varies with eluant flow rate, check flow before injecting each sample, and adjust as necessary.

(b) *Liquid chromatographic column*.—No. 316 stainless steel,  $1000 \times 2.1$  (id) mm, packed with DuPont No. 820960005 SAX (strong anion exchange) resin. Ready-to-use column is available as DuPont No. 830950405.

(c) *Eluants*.—(1) *Primary eluant*.—0.01M aq.  $\text{Na}_2\text{B}_4\text{O}_7$  (2 g/L). (2) *Secondary eluant*.—0.01M aq.  $\text{Na}_2\text{B}_4\text{O}_7$  (2 g/L) in 0.50M aq.  $\text{NaClO}_4 \cdot \text{H}_2\text{O}$  (70.2 g/L).

★ Surplus method—see inside front cover.

**34.060 Sample Preparation and Resolution**

Accurately weigh ca 1.000 g sample into 10 mL vol. flask, and dissolve and dil. to vol. with primary eluant.

Before injecting first sample, run blank (0–100%) gradient; then pump primary eluant thru column 14 min. Immediately inject 5.0  $\mu$ L sample soln into chromatograph, using  $\mu$ L syringe. Start 0–100% gradient at once and maintain final composition until chromatogram is complete (ca 50 min). Pump primary eluant thru column 14 min; then inject next sample. (*Blank* 0–100% gradient can be run at 10%/min; however, sample gradients must be run at 1%/min.)

**34.061 Calibration**

Accurately weigh ca 0.2000 g (100% basis) DAADBSA into 5 mL vol. flask, and dissolve and dil. to vol. with primary eluant. Prep. soln of ca 1.000 g DAADBSA-free FD&C Yellow No. 6 in 10 mL primary eluant, as in **34.060**. Transfer 5  $\mu$ L DAADBSA soln to DAADBSA-free FD&C Yellow No. 6 soln with  $\mu$ L syringe, mix, and inject. Add 2 more 5  $\mu$ L portions DAADBSA soln, mix, and inject into chromatograph after each addn. This provides min. of 3 stds (0.02, 0.04, and 0.06% DAADBSA). Addnl stds contg 0.005, 0.03, and 0.05% DAADBSA are desirable.

**34.062 Calculations**

Det. area (peak ht  $\times$  width at half ht, in sq mm) of DAADBSA peak in each spiked sample. Correct area for any area due to DAADBSA in FD&C Yellow No. 6, plot area against % DAADBSA added, and use this plot to det. % DAADBSA in samples. Report results to nearest 0.001% as DAADBSA disodium salt, MW 401.32.

**Intermediates in FD&C Red No. 40 (14)**  
**Official First Action**

**34.063 Principle**

FD&C Red No. 40 (C.I. No. 16035) is more strongly adsorbed on cellulose from concd  $(\text{NH}_4)_2\text{SO}_4$  soln than are dye intermediates. 5-Amino-4-methoxy-2-toluenesulfonic acid (CSA) and Schaeffer's salt elute sep. with 40%  $(\text{NH}_4)_2\text{SO}_4$ ; 6,6'-oxybis(2-naphthalensulfonic acid) (DONS) elutes with 20%  $(\text{NH}_4)_2\text{SO}_4$ . Each intermediate is detd by UV spectrophotometry.

**34.064 Apparatus**

See **34.054**.

**34.065 Reagents**

See **34.055**.

**34.066 Preparation of Chromatographic Column**

See **34.056**. Prep. and elute similar column as blank. Blank need be repeated only when new reagents are introduced.

**34.067 Separation of Intermediates**

Weigh 0.100 g sample into 50 mL beaker. Add 5 mL  $\text{H}_2\text{O}$  and stir to dissolve. Proceed as in **34.057**, beginning "Add 2 g cellulose powder . . .", except elute with ca 1.5 L 20%  $(\text{NH}_4)_2\text{SO}_4$ .

**34.068 Calculations**

See **34.058**. CSA normally elutes in fractions 4–6, Schaeffer's salt in fractions 8–10, and DONS in fractions 16–30.

% CSA (as free acid, MW 217.2)  

$$= 0.186 \times \Sigma[(A_1 - A_2)_{252} - (A_3 - A_4)_{360}]$$

% Schaeffer's salt (as Na salt, MW = 246.2)  

$$= 0.395 \times \Sigma[(A_1 - A_2)_{282} - (A_3 - A_4)_{360}]$$

% DONS (as di-Na salt, MW 474.4)  

$$= 0.0585 \times \Sigma[(A_1 - A_2)_{240} - (A_3 - A_4)_{360}]$$

Effective sample concn is 2 g/L; 53.8, 25.3, and 171 =  $a$  (L/g-cm) of CSA, Schaeffer's salt, and DONS, resp; see **34.058** for calcn of constants.

**METALS****Lead—Official Final Action****Method I (20)**

(Applicable to colors not contg Ca, Ba, or Sr)

**34.081****Reagents**

- (a) *Lead std solns.*—See 25.095(a).
- (b) *Dilute nitric acid.*—1%. See 25.095(b).
- (c) *Citric acid soln.*—50%. Special grade—low in Pb. See 25.095(d).
- (d) *Diphenylthiocarbazon (dithizone) soln.*—Stock soln of purified dithizone in  $\text{CHCl}_3$  contg 1.00 mg/mL. Also working soln contg 20 mg/L. See 25.095(e).
- (e) *Potassium cyanide soln.*—10%. Dissolve 50 g phosphate-free KCN in  $\text{H}_2\text{O}$  and dil. to 500 mL. (Caution: See 51.050.)
- (f) *Hydroxylamine hydrochloride soln.*—10%. Dissolve 10 g  $\text{H}_2\text{NOH.HCl}$  in 20 mL  $\text{H}_2\text{O}$  and make slightly alk. with  $\text{NH}_4\text{OH}$ . Ext Pb with dithizone. Remove excess dithizone with  $\text{CHCl}_3$  and boil off any  $\text{CHCl}_3$  remaining in aq. phase. Acidify with  $\text{HCl}$  and dil. to 100 mL.
- (g) *Thymol blue indicator.*—0.1%. Dissolve 0.1 g thymol blue in  $\text{H}_2\text{O}$ , add enough 0.1N  $\text{NaOH}$  to change color to blue, and dil. to 100 mL.

**34.082****Preparation of Sample**

(Caution: See 51.019, 51.026, 51.028, and 51.030.)

Transfer 5.00 g sample to 500 mL Kjeldahl flask, add 10 mL  $\text{H}_2\text{SO}_4$  and 10 mL  $\text{HNO}_3$ , and heat. When  $\text{SO}_3$  fumes begin to evolve, add 5 mL  $\text{HNO}_3$  and heat until  $\text{SO}_3$  again evolves. Repeat addn of  $\text{HNO}_3$  each time  $\text{SO}_3$  fumes appear until dye is completely in soln and digest is yellow. Then add 10 mL of mixt. of  $\text{HNO}_3$  and 60–70%  $\text{HClO}_4$  (1+1), and continue heating until digest is colorless or pale yellow and bulk of  $\text{H}_2\text{SO}_4$  is evapd.

Cool flask under running  $\text{H}_2\text{O}$  and neutze soln by addns of small portions of  $\text{NH}_4\text{OH}$ . Add 20 mL citric acid soln and adjust to pH 8.5–9 with  $\text{NH}_4\text{OH}$ , using 4 drops thymol blue indicator. Add 5 mL 10% KCN soln.

★ Surplus method—see inside front cover.

Transfer alk. soln to 250 mL Pyrex separator. Ext Pb with 20 mL portion dithizone soln contg 20 mg/L. (Note: If enough Fe is present to cause excessive oxidn of dithizone as indicated by yellow color in  $\text{CHCl}_3$  layer, add 10 mL 10%  $\text{H}_2\text{NOH.HCl}$  soln to reduce the Fe.) Let  $\text{CHCl}_3$  layer settle and drain into another separator. Wash down floating globules of  $\text{CHCl}_3$  with two 5 mL portions of less concd dithizone soln (4 mg/L) and add to receiving separator. Repeat extns with the more concd dithizone soln until no more red Pb dithizonate is observed. Make 2 more extns with 10 mL portions less concd dithizone soln.

Add 25 mL 1%  $\text{HNO}_3$  to separator contg combined dithizone exts. Shake, let settle, and drain green dithizone layer into another separator contg addnl 25 mL 1%  $\text{HNO}_3$ . Shake, let layers sep., and discard  $\text{CHCl}_3$  fraction. Combine 1%  $\text{HNO}_3$  exts.

**34.083****Determination**

Det. Pb in combined 1%  $\text{HNO}_3$  exts as in 25.100.

**Method II (21)**

(Applicable to Al lakes)

**34.084****Apparatus**

See Fig. 34.02. Pptn tube B is fitted with inlets for addn of sample and of  $\text{H}_2\text{S}$  and for release of  $\text{H}_2\text{S}$  and transfer of pptd PbS to filter in C (fine porosity fritted glass covered with Celite)

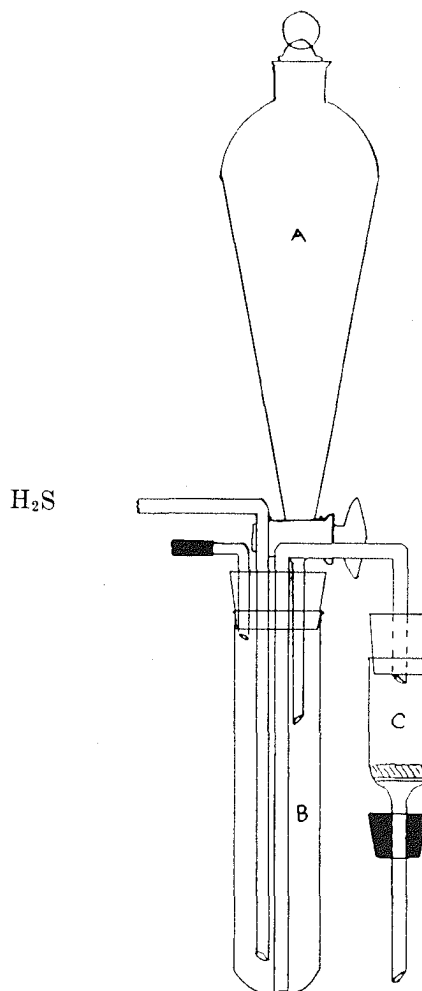

FIG. 34.02—Sulfiding apparatus (full scale)

or other similar filter-aid). For 20–300  $\mu\text{g}$  Pb, ca 0.5 g filter-aid is enough to allow rapid filtration with complete retention of ppt. Filter must be thoroly washed with  $\text{HNO}_3$  followed by  $\text{H}_2\text{O}$  before use.

Wash all glassware successively with scouring powder,  $\text{H}_2\text{O}$ ,  $\text{HNO}_3$ , and again with  $\text{H}_2\text{O}$ . Wash pptn app. with  $\text{HNO}_3$  and  $\text{H}_2\text{O}$  between detns.

**34.085****Reagents**

All reagents should be Pb-free. See 25.095. Any source of  $\text{H}_2\text{S}$  may be used. Scrub gas first with  $\text{H}_2\text{SO}_4$  (1+1), and then with  $\text{H}_2\text{O}$  before passing into soln.

**34.086****Determination**

(Caution: See 51.019, 51.026, 51.028, 51.030, and 51.059.)

Weigh 2 g sample into 500 mL Kjeldahl flask, add 10 mL  $\text{H}_2\text{SO}_4$  and 10 mL  $\text{HNO}_3$ , and digest over low flame until  $\text{SO}_3$  fumes appear. Add 5 mL portions  $\text{HNO}_3$  (waiting until  $\text{SO}_3$  fumes appear before adding each succeeding portion) until all org. matter is in soln. Slowly add 5–10 mL mixt. of  $\text{HNO}_3$  and 60–70%  $\text{HClO}_4$  (1+1), and continue digestion until white ppt formed shows first signs of spattering. Let flask cool, and cautiously add 5 mL  $\text{H}_2\text{O}$  and then few drops  $\text{NH}_4\text{OH}$ . Vigorously swirl flask and cool under running  $\text{H}_2\text{O}$ . Add 20 mL citric acid soln, 34.081(c), and adjust to pH 3.0–3.4 (bromophenol blue) with  $\text{NH}_4\text{OH}$ . Add 1 mL  $\text{CuSO}_4$  soln (1 mg Cu/mL) and transfer soln to pptn tube, B, of sulfiding app., Fig. 34.02. Bubble  $\text{H}_2\text{S}$  thru soln 3–5 min at ca 2 bubbles/sec and filter resulting suspension thru C at rate of ca 1 drop/sec. When filtration is complete, remove receiver contg filtrate and attach suction test tube.

Add 3 mL hot  $\text{HNO}_3$  thru separator A and draw thru filter; follow with 2 mL hot  $\text{H}_2\text{O}$ . Detach filter and pass addnl 3 mL hot  $\text{HNO}_3$  thru filter, wetting all sides. Again follow with 2 mL hot  $\text{H}_2\text{O}$ . If filter is still colored with PbS, wash again with hot  $\text{HNO}_3$  and  $\text{H}_2\text{O}$ . Wash dissolved sulfides into pptn tube B, wetting all sides to take up any residual PbS and then into 50–100 mL g-s erlenmeyer. Stopper, and shake few sec; remove stopper and boil until soln clears, to remove last traces of  $\text{H}_2\text{S}$  and to coagulate any free S present.

Transfer soln to 250 mL separator. Wash flask with two 5 mL portions  $\text{H}_2\text{O}$  and add washings to main soln. Add 10 mL citric acid soln, 5 mL 10% KCN soln, and few drops of  $\text{H}_2\text{NOH.HCl}$  soln, 34.081(f), to prevent oxidn of dithizone; adjust pH to 8.5–9.5 (thymol blue) with  $\text{NH}_4\text{OH}$ .

Immediately ext with 20 portions dithizone, 34.081(d), using the more dil. soln unless exceptionally large amts of Pb are present. Shake 20–30 sec, let layers sep., and note color of  $\text{CHCl}_3$  phase. (Pb dithizone complex is red, but color may be masked by excess green dithizone, giving intermediate hues of purple and crimson. Color of  $\text{CHCl}_3$  ext gives first indication of amt of Pb present, and progress of extn can be followed by noting color of successive exts.)

Drain  $\text{CHCl}_3$  layer into 125 mL short-stem separator contg 25–30 mL  $\text{H}_2\text{O}$  made ammoniacal with one drop  $\text{NH}_4\text{OH}$  (sp gr 0.90). Continue extn until 2 successive exts with small portions of more dil. dithizone solns show the neg. color (green, not bluish or purple), combining exts in smaller separator. Shake, let layers sep., drain  $\text{CHCl}_3$  fraction into another small separator, and repeat washing process as before. Drain  $\text{CHCl}_3$  fraction as cleanly as possible into 100 or 150 mL beaker, and pass small portion of dil. dithizone soln thru separators in succession so as to wash out small portions of ext persisting in aq. fraction. Add to beaker and evap.  $\text{CHCl}_3$  with gentle heat on steam bath. Take up dry residue with 3–4 mL  $\text{HNO}_3$ , and heat by swirling over

low flame. Dil. to ca 25 mL and continue heating 1–2 min to expel oxides of N. Add small piece of litmus paper, neutze with  $\text{NH}_4\text{OH}$ , and dil. to 50 mL. Add 0.5 mL  $\text{HNO}_3$  and proceed as in 25.100.

**34.087 Method III (21)**

(Applicable to Ca, Ba, and Sr lakes)

Place 2 g sample, 4 g  $\text{Na}_2\text{CO}_3$ , 6 g  $\text{K}_2\text{CO}_3$ , and 0.5 g  $\text{NaNO}_3$  in Pt crucible and mix thoroly. Heat carefully until sample is carbonized; then heat to ca  $850^\circ$  and hold at that temp. 15 min. (If temp.-controlled furnace is available, it is only necessary to place fusion mixt. in cold furnace and raise temp. gradually to  $850^\circ$  over 2 hr period. Usually 15 min heating at  $850^\circ$  will complete fusion.)

Let crucible and contents cool to  $<100^\circ$ ; then add 2 or 3 mL  $\text{H}_2\text{O}$  and heat over low flame, using care to prevent spattering, until contents can be sepd from crucible. Transfer fused mixt. to 150 mL beaker with aid of ca 25 mL hot  $\text{H}_2\text{O}$ . Boil until caked material is completely disintegrated, and filter thru retentive paper. Wash residue on filter with two 15 mL portions hot 5%  $\text{Na}_2\text{CO}_3$  soln. Pb will be in both filtrate and residue. Transfer filtrate to separator and ext Pb from filtrate as in 34.086.

Dissolve residue on filter in 10–20 mL  $\text{HCl}$  (2+5), wash filter with  $\text{H}_2\text{O}$ , and add washings to filtrate. Boil soln to expel  $\text{CO}_2$ ; then transfer to separator and ext Pb as above. Combine with  $\text{CHCl}_3$  exts from sol. portion of fusion products and det. total Pb as in 34.086.

**SOLUBLE MATTER—OFFICIAL FIRST ACTION****34.100 Water-Soluble Matter**

Place 5 g well powd sample in 500 mL erlenmeyer or wide-mouth bottle, add 200 mL H<sub>2</sub>O, stopper, and shake vigorously. Repeat mixing several times during 2 hr period. Filter, and evap. 100 mL filtrate in weighed Pt dish on steam bath. Dry in oven at 100–105°, cool in desiccator, and weigh. Report increase in wt as H<sub>2</sub>O-sol. matter. Test small portions of remainder of filtrate for chlorides, sulfates, and nitrates. If more than traces are present, make proper analyses on aliquot portions of filtrate.

**34.101 Chloroform-Soluble Matter**

Weigh 5 g sample into cellulose thimble and ext in Soxhlet app. with CHCl<sub>3</sub> 16 hr. Transfer ext to separator and wash with 30 mL portions H<sub>2</sub>O until washings are practically colorless. Ext combined washings with ca 30 mL CHCl<sub>3</sub> and add washings to main ext. Drain CHCl<sub>3</sub> ext into weighed dish. Wash separator with few mL CHCl<sub>3</sub> and add washings to dish. Evap. at room temp., dry in desiccator to const wt (±0.5 mg), and weigh. Report as CHCl<sub>3</sub> ext.

## 35. Cosmetics

### GENERAL METHODS

#### Water and Ethyl Alcohol (1)—Official First Action

##### 35.001

##### Principle

Sample is dissolved or dispersed in ethylene glycol monomethyl ether, which also serves as internal std, and H<sub>2</sub>O and alcohol are detd by GLC, using relatively inert column, perfluorocarbon substrate coated with high MW polyethylene glycol, to minimize tailing.

##### 35.002

##### Apparatus

**Gas chromatograph.**—With thermal conductivity detector operated at following temps (°): Detector ca 250, injection port ca 260, oven, ca 100; He flow rate, 50 mL/min; bridge current, as directed by manufacturer.

##### 35.003

##### Standard Solutions

Prep. 3 std solns in 125 mL g-s flasks contg H<sub>2</sub>O and absolute alcohol, weighed to 0.1 mg, in ethylene glycol monomethyl ether weighed to 10 mg, as follows:

H <sub>2</sub> O, mg	Alcohol, mg	Ethylene Glycol Monomethyl Ether, g
125	375	24.50
250	250	24.50
375	125	24.50

H<sub>2</sub>O content of ethylene glycol monomethyl ether should be <0.05%. Use same batch for stds and samples. Com. product is usually satisfactory, but because of hygroscopicity, *expose solns to air as little as possible.*

##### 35.004

##### Preparation of Column

Weigh 10 g polyethylene glycol 20000 (Carbowax 20M) into 800 mL beaker, dissolve completely in ca 400 mL warm CH<sub>2</sub>Cl<sub>2</sub>, and cool to ca 0°. Slurry cold soln with 190 g precooled (ca 0°) Fluoropak 80, 40–60 mesh (Applied Science Laboratories). Transfer to 15 cm crystg dish, place in hood, and evap. to dryness at room temp. with occasional stirring. Recool to ca 0° and screen thru No. 40 on No. 60 precooled screen. Pack fraction remaining on No. 60 in 4.6 m (15') × ¼" precooled Cu column, using vibrator. (Use of cooled column packer (Press-Pak, available from Alltek Associates, 202 Campus Dr, Arlington Hts, IL 60004) at 35 lb/sq in. (240 kPa) N pressure allows packing of cooled, precoiled column.)

##### 35.005

##### Standardization

Inject 3 µL of one of std solns with 10 µL syringe and det. elution time of ethylene glycol monomethyl ether. (Order is alcohol, H<sub>2</sub>O, and glycol ether.) Adjust oven temp., if necessary, so latter elutes in 15–20 min. With satisfactory column, pen will return to within 1% of recorder 0 between alcohol and H<sub>2</sub>O peaks. Det. sample size for each std soln such that response for smallest peak is ≥¼ full scale on ×1 attenuation. Det. all attenuations necessary to keep all peaks on chart scale. (Too large samples will overload column and skew glycol ether peak.)

With some gas chromatographs, alcohol peak response will vary with time interval between emergence of glycol ether of previous injection and injection of sample. Thus, inject all samples (std curves and actual detns) at same time interval after

emergence of glycol ether. This requires use of preliminary sample. If time sequence is broken, inject another preliminary sample to re-establish sequence.

Obtain chromatograms, in duplicate, and on same day, for each std soln, using sample sizes and attenuations detd above. Duplicate sample sizes to 0.1 µL and use same technic for injecting and withdrawing syringe needle. Det. peak ht of each component, correcting for attenuation.

Calc. ratios: peak ht H<sub>2</sub>O/peak ht ethylene glycol monomethyl ether ( $R_{PW}$ ), and wt H<sub>2</sub>O/wt ethylene glycol monomethyl ether ( $R_{WW}$ ). Average the 2  $R_{PW}$  values for each std soln and plot av.  $R_{PW}$  values against corresponding  $R_{WW}$  values. Draw best straight line thru 3 points. Make same calcs for alcohol stds, and plot corresponding  $R_{PA}$  and  $R_{WA}$  values. (Curves should be straight lines intersecting x or y axis near origin.)

##### 35.006

##### Determination

Accurately weigh sample contg ca 100–400 mg H<sub>2</sub>O and/or alcohol into 125 mL g-s flask, add 24.50±0.1 g ethylene glycol monomethyl ether, and mix thoroly. (Complete soln is unnecessary but glycol ether phase should contain all the H<sub>2</sub>O and alcohol.) Det. proper sample size as in 35.005, recording necessary attenuations. From good chromatogram, calc.  $R_{PW}$  and  $R_{PA}$  values. Read  $R_{WW}$  and  $R_{WA}$  values from std curves. From latter values prep. *final std soln* of 24.50 g ethylene glycol monomethyl ether plus H<sub>2</sub>O and/or alcohol which approximates (within 10%) curve of sample. Det., in sequence, (a) curve of proper size sample, (b) curve of adjusted *final std soln*, and repeat (a) and (b), in that order. Det. av.  $R_{PW}$  and  $R_{PA}$  values of unknown and final std solns, then  $R_{WW}$  and  $R_{WA}$  of std soln.

For H<sub>2</sub>O:  $R_{WW}(\text{sample}) = R_{PW}(\text{sample}) \times R_{WW}(\text{std})/R_{PW}(\text{std})$ ; wt H<sub>2</sub>O (sample) = wt ethylene glycol monomethyl ether (sample) ×  $R_{WW}(\text{sample})$ ; and % H<sub>2</sub>O (sample) = (wt H<sub>2</sub>O/wt sample) × 100.

For alcohol:  $R_{WA}(\text{sample}) = R_{PA}(\text{sample}) \times R_{WA}(\text{std})/R_{PA}(\text{std})$ ; wt alcohol (sample) = wt ethylene glycol monomethyl ether (sample) ×  $R_{WA}(\text{sample})$ ; and % alcohol (sample) = (wt alcohol/wt sample) × 100.

#### Propylene Glycol (2)—Official Final Action

(Applicable to all types of cosmetics)

##### 35.007

##### Apparatus

(a) **Distillation apparatus.**—All-glass, with 20/40 joints: 250 mL r-b flask, elec. heating mantle, 20 mL Barrett H<sub>2</sub>O trap with stopper, and driptip condenser.

(b) **Gas chromatograph.**—With H flame detector and capable of operating at ca 200°.

(c) **GLC column.**—1.8 m (6') × ¼" od Cu or Al column packed with 80–100 mesh Chromosorb 101. Pack resin in column, using vibrator and column packer, 35.004, operated at 25–35 lb (170–240 kPa) pressure. Heat column overnight at 240° with He flow rate ca 100 mL/min. Condition column with propylene glycol as in 35.010. Inject enough aq. soln of propylene glycol-trimethylene glycol (1+1) to give ≥½ full-scale response. If column is satisfactory, 2 symmetrical peaks will be obtained. Reject batches of Chromosorb 101 which give unsymmetrical peaks.

##### 35.008

##### Reagents

(a) **Propylene glycol.**—Eastman Kodak Co. No. 1321, or equiv.; assay by periodate oxidn as in 19.009 (a).

(b) *Trimethylene glycol*.—Propylene glycol-free.

(c) *Isooctane (2,2,4-trimethylpentane)*.—Bp 99–100°.

(d) *Propylene glycol and trimethylene glycol std solns*.—10 mg/mL. Prep. sep. std solns. Accurately weigh ca 1.0 g std, dissolve in H<sub>2</sub>O, transfer to 100 mL vol. flask, and dil. to vol.

### 35.009 Separation of Propylene Glycol by Co-distillation

(Caution: See 51.011, 51.039, and 51.062.)

Accurately weigh sample contg ca 2–40 mg propylene glycol into 250 mL r-b flask. Add 8–10 mL H<sub>2</sub>O and few boiling chips. Connect flask to distn app. and add, thru condenser, enough isooctane to fill H<sub>2</sub>O trap and provide 25–40 mL isooctane in distn flask. Adjust voltage on heating mantle so that isooctane distils at 5–10 mL/min. Continue distn 30 min after all H<sub>2</sub>O appears to be collected in trap. Drain as much H<sub>2</sub>O as possible (leave ca 0.25 mL in H<sub>2</sub>O trap) into small g-s container. (Stoppered 25 mL graduate is convenient.) Remove heat from distn flask and, when boiling stops, disconnect flask from app. and add 5 mL H<sub>2</sub>O. Reconnect to app. and distil as before. Drain distillate into container contg first H<sub>2</sub>O distillate. Repeat with second 5 mL portion H<sub>2</sub>O. Mix combined distillates.

### 35.010 Preparation of Instrument

With Chromosorb 101 column in gas chromatograph, set column temp. at ca 180°, injection port and detector temps at ca 300°, and He flow rate near 70 mL/min. If necessary, adjust column temp. to elute propylene glycol in ca 6 min. Condition column by initial 0.5  $\mu$ L injection of propylene glycol. Column must be conditioned in this manner once a day before use for detg propylene glycol. Use 5  $\mu$ L aq. test soln contg ca 1 mg propylene glycol/mL and adjust H and air flow to flame detector until max. response is obtained. (See manufacturer's directions.) Note range and attenuation settings needed to keep peak on scale.

Establish rough calibration curve of peak ht response against wt propylene glycol by injecting known amts propylene glycol and observing response.

### 35.011

#### Determination

Det. approx. propylene glycol content of aq. soln, obtained by codistn of sample with isooctane, by injecting known amt distillate into chromatograph. To sample soln add known aliquot of std trimethylene glycol soln (preferably sample soln should contain approx. equal wts propylene glycol and trimethylene glycol). Prep., from accurately measured aliquots of stds, soln contg approx. same wt propylene glycol and trimethylene glycol as prep sample and dil. to approx. same vol. as sample soln.

Det., by trial injections, resp. vols of sample and std solns required to give nearly equal responses of ca ¾ full-scale for propylene glycol. Alternately inject these vols sample and known solns, making  $\geq 2$  injections of each soln. Det. sample and its corresponding std at same range and attenuation settings.

### 35.012

#### Calculations

From chromatograms, calc. following peak ht ratios for sample, *R*, and std, *R'*, resp.:

$R$  = peak ht propylene glycol/peak ht trimethylene glycol

$R'$  = peak ht propylene glycol/peak ht trimethylene glycol,

Using av. values of *R* and *R'*, calc. amt propylene glycol in sample.

mg Propylene glycol =  $(R/R') \times \text{mg propylene glycol (std)} \times [\text{mg trimethylene glycol (sample)}]/[\text{mg trimethylene glycol (std)}]$

(If same aliquot of trimethylene glycol is used for prep sample and std, last factor = 1.)

## DEODORANTS AND ANTIPERSPIRANTS

### Aluminum and Zinc (3)—Official Final Action

#### 35.013

#### Reagents

(a) *8-Hydroxyquinoline soln*.—Dissolve 5.0 g 8-hydroxyquinoline in 12 mL HOAc, dil. to 100 mL with H<sub>2</sub>O, and filter if not clear. Prep. fresh soln  $\leq 2$  weeks.

(b) *Ammonium acetate soln*.—Approx. 2*N*. Dissolve 150–160 g NH<sub>4</sub>OAc in 1 L H<sub>2</sub>O and filter if not clear.

(c) *Hydrochloric acid*.—Approx. 2*N* (1+5).

(d) *Ammonium hydroxide*.—Approx. 2*N*. Vol. of NH<sub>4</sub>OH required to neutze 20 mL 2*N* HCl, (c), should be known to within  $\pm 2$  mL.

#### 35.014

#### Preparation of Sample

(a) *Liquids*.—Dil. 5 mL sample to 250 mL with H<sub>2</sub>O in vol. flask. If perfume oils sep., filter before taking aliquot for analysis.

(b) *Creams and pastes*.—Accurately weigh 2–3 g sample into 250 mL beaker. Add 5 mL HCl (HNO<sub>3</sub> if chlorides are to be detd) and ca 50 mL H<sub>2</sub>O, and heat until oils liquefy and sep.; cool until oils solidify, and decant aq. layer thru fluted paper into 250 mL vol. flask. Return filter to original beaker and macerate thoroly. Repeat above extn twice, decant as before, and finally thoroly wash residue and paper with H<sub>2</sub>O. (It is unnecessary to return filter paper to beaker after these extns.) Cool combined exts to room temp., dil. to vol. with H<sub>2</sub>O, and mix.

(c) *Solids*.—Accurately weigh 2–3 g sample into 250 mL beaker, add 5 mL HCl (HNO<sub>3</sub> if chlorides are to be detd) and ca 50 mL H<sub>2</sub>O, and heat to bp. Cool, and filter thru fluted paper into 250 mL vol. flask. If filtrate is cloudy, refilter thru fine quant. paper. Thoroly wash beaker and paper with H<sub>2</sub>O. Cool flask and contents to room temp., dil. to vol. with H<sub>2</sub>O, and mix.

#### 35.015

#### Determination

(a) *Interfering metals absent*.—Take aliquot of sample soln contg 12–25 mg Al or 20–60 mg Zn. Add 1–2 drops phthln, and then add 2*N* NH<sub>4</sub>OH until neut. or until faint permanent turbidity results. Add 5 mL HOAc (1+9), dil. to ca 100 mL, and heat to 70–90°. Add 10 mL 8-hydroxyquinoline soln and then slowly add NH<sub>4</sub>OAc soln until 20 mL (see Note) in excess of vol. required to produce permanent ppt has been added. If permanent ppt forms on addn of 8-hydroxyquinoline, add only 20 mL NH<sub>4</sub>OAc soln. Heat below bp 2–5 min and set aside 30–60 min. (Moderate excess of 8-hydroxyquinoline is required for complete pptn. If enough reagent has been added, soln will be yellow at this point; if it is not, repeat detn, using larger vol. of 8-hydroxyquinoline soln.) Filter thru tared gooch, wash thoroly with H<sub>2</sub>O, dry 1–2 hr at 130–140°, cool, and weigh. Dry again 30 min, cool, and weigh. Repeat to const wt ( $\pm 0.3$  mg). (Alternatively, ppt may be dried overnight.)

Wt ppt  $\times 0.05871$  = Al;

Wt ppt  $\times 0.1848$  = Zn

*Note:* Final pH of soln from which metals are pptd should be 4.9–5.1. Vol. of NH<sub>4</sub>OAc soln required to produce this pH should be detd experimentally each time new set of reagents is prepd. If NH<sub>4</sub>OAc is of usual purity, ca 20 mL soln will be required.

(b) *In presence of magnesium*.—Ppt as in (a) and set aside ca 30 min. Decant most of liq. thru quant. paper (part or all of ppt may be transferred to paper if necessary) and discard filtrate. Place beaker used for pptn under funnel and dissolve ppt on paper in hot 2*N* HCl (20 mL is usually enough if added in several small portions). Wash paper and funnel with 20–30 mL H<sub>2</sub>O. Add 2 mL 8-hydroxyquinoline soln, 5 mL HOAc (1+9), and vol.

of 2*N*  $\text{NH}_4\text{OH}$  equiv. to 2*N*  $\text{HCl}$  used to dissolve ppt (do not use excess). Dil. to ca 100 mL, heat to 70–90°, and proceed as in (a), beginning “. . . slowly add  $\text{NH}_4\text{OAc}$  soln . . .”

#### Zinc (4)—Official Final Action

##### 35.016

##### Reagent

**8-Hydroxyquinoline soln.**—Dissolve 5.0 g 8-hydroxyquinoline in 12 mL  $\text{HOAc}$ , dil. to 100 mL with  $\text{H}_2\text{O}$ , and filter if soln is not clear. (Soln is stable ca 1 week. If only tech. grade base is available, purify by recrystn from alcohol (2+1), using 6 mL solv. for each g base, before prep g soln.)

##### 35.017

##### Determination

Pipet aliquot of sample soln, **35.014**, contg 20–50 mg Zn, into 400 mL beaker. Adjust soln to slight acidity, add 1 g  $\text{NH}_4$  tartrate if Al is present, and then add 2 mL 8-hydroxyquinoline soln for each 10 mg Zn present; dil. to 200 mL and heat to 60–80°. Neutze excess acid by adding  $\text{NH}_4\text{OH}$  (1+4) until Zn complex salt that forms on addn of each drop just redissolves on stirring. Slowly add, with stirring, 45 mL  $\text{NH}_4\text{OAc}$  soln, **35.013(b)**, and let mixt. come to room temp.

Det. pH of soln; if pH is not 5.7–5.9, adjust with the  $\text{NH}_4\text{OH}$  soln, and let mixt. stand 10–20 min to achieve equilibrium. Decant thru tared gooch and wash ppt in beaker twice with hot  $\text{H}_2\text{O}$ , decanting each wash into crucible. Finally transfer ppt to crucible and again wash with hot  $\text{H}_2\text{O}$ . (Total vol. washings should be >200 mL.) Dry crucible and ppt 2 hr at 130–140°, cool, and weigh. Reheat 30 min at 130–140°; cool, reweigh, and repeat heating, cooling, and weighing to const wt.  $\text{Wt ppt} \times 0.1712 = \text{wt Zn}$ .

#### 35.018 Aluminum—Official Final Action

Multiply wt Zn found, **35.017**, by 5.411 to obtain equiv. wt 8-hydroxyquinoline salt, multiply by appropriate factor for aliquot taken, and subtract from wt combined Al and Zn salts, **35.015**.  $\text{Difference} \times 0.05871 = \text{wt Al}$ .

#### Soluble Zirconium in Antiperspirant Aerosols

##### Colorimetric Method (5)—Official First Action

##### 35.019

##### Reagents

(a) **Alizarin red S (sodium alizarin sulfonate) soln.**—Dissolve 1.5 g alizarin red S indicator (Allied Chemical Corp., or equiv.) in 300 mL hot  $\text{H}_2\text{O}$ . Cool and filter thru double layer of rapid, medium porosity paper (Whatman No. 12, 24 cm folded, or equiv.). Dil. filtrate to 1 L with  $\text{H}_2\text{O}$ , and refilter. Soln is stable  $\geq 1$  month.

(b) **Zirconyl chloride octahydrate.**—Fisher No. Z-80, or equiv. Assay as in **35.020**.

##### 35.020

##### Assay of Standard

Accurately weigh 500–600 mg  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$  into 400 mL beaker and dissolve in 50 mL  $\text{H}_2\text{O}$ . Add 4 g  $\text{NH}_4\text{NO}_3$  and warm on steam bath to ca 50°. Slowly add, with stirring, 100 mL  $\text{NH}_4\text{OH}$  and continue heating 20 min. Filter while hot thru 15 cm Whatman No. 42, or equiv., paper. Complete transfer of ppt with 2–3 portions 2%  $\text{NH}_4\text{NO}_3$  in  $\text{NH}_4\text{OH}$  (2+98). Carefully fold paper and place in ca 50 mL Pt crucible. Dry in oven at 105°. Partially cover crucible and gently heat with Meker burner until paper is well charred. Continue heating at max. burner temp. to const wt.

$$\% \text{ Zr} = \text{ZrO residue} \times 74.03 / \text{wt } \text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$$

##### 35.021

##### Preparation of Standard Curve

Dissolve  $\text{ZrOCl}_2 \cdot 8\text{H}_2\text{O}$  contg 200 mg Zr in 70 mL  $\text{H}_2\text{O}$  in 200 mL vol. flask. Add 110 mL  $\text{HCl}$ , cool, and dil. to vol. with  $\text{H}_2\text{O}$ . Prep. this 1 mg/mL stock soln fresh weekly. Pipet 2, 5, 10, and 15 mL stock soln into 100 mL vol. flasks. Dil. each to vol. with  $\text{HCl}$  (55+45), and mix. Pipet 5 mL each dil. std and, as blank, 5 mL  $\text{HCl}$  (55+45) into sep. 100 mL vol. flasks for color development (0, 100, 250, 500, and 750  $\mu\text{g Zr}/100 \text{ mL}$ ). Add to each flask 10.0 mL alizarin red S soln, (a), and 8 mL  $\text{H}_2\text{O}$ . Swirl and place in  $75 \pm 3^\circ \text{H}_2\text{O}$  bath. Monitor temp. of solns with thermometer in 100 mL vol. flask contg 23 mL  $\text{H}_2\text{O}$  added at room temp. and placed simultaneously in bath. Swirl flasks occasionally while heating. After solns reach 70°, keep flasks in bath addnl  $6.5 \pm 1$  min. Remove and let cool 20 min at room temp. Dil. each to vol. with  $\text{H}_2\text{O}$  and mix. Measure *A* in 2 cm cells against blank at 525 nm, scanning on recording spectrophtr from 700–460 nm. Plot *A* against  $\mu\text{g Zr}/100 \text{ mL}$ .

(If 750  $\mu\text{g Zr}/100 \text{ mL}$  cannot be read on *A* scale, use higher range of spectrophtr or 14.0 mL aliquot (700  $\mu\text{g Zr}/100 \text{ mL}$ ).)

##### 35.022

##### Preparation of Sample

Remove cap and any paper wrapping from aerosol can. Record wt of can to nearest 0.01 g. Replace cap and freeze contents by placing inverted can in beaker contg mixt. of solid  $\text{CO}_2$  and acetone and cooling  $\geq 1$  hr. Transfer can to smaller beaker in exhaust hood and cautiously open bottom end with can opener, keeping end partially attached to can. Let volatile gases escape at room temp. Remove dip tube after initial thawing when gas evolution has subsided, but keep tube with can in beaker. Place beaker on steam bath, and heat gently to evolve higher boiling gases. Increase heat slowly and maintain until bubbling subsides. Place beaker contg can and dip tube in 70° forced-draft oven 45 min. Raise temp. to 115° and maintain 2.5 hr, stirring occasionally with stainless steel spatula. Remove from oven and let cool to room temp. Thoroughly mix contents, including any portion clinging to sides, to form homogeneous conc. Weigh can plus contents, spatula, and dip tube. Stir contents ca 1 min and weigh again. Repeat stirring and weighing until wt is const to within 0.01 g. Record wt and immediately transfer contents to g-s weighing bottle (quant. transfer unnecessary). Stopper bottle and protect from further wt loss by opening only when necessary.

Remove cap from can and thoroly remove remaining contents from can, spatula, and dip tube with  $\text{H}_2\text{O}$  and alcohol. Dry cap, can, spatula, and dip tube to const wt at 110°. Obtain wt of conc. by subtracting latter wt from wt previously recorded after drying contents. Obtain wt of intact can contents by subtracting wt of clean, dry can (without cap) and dip tube from gross wt initially recorded.

##### 35.023

##### Determination

Record gross wt of prepd sample in weighing bottle. Mix sample briefly and remove ca 1 g with spatula. Calc. wt removed as difference in gross wt.

Transfer sample as completely as possible from spatula to lower half of 600 mL beaker. Thoroly wipe spatula with small piece of filter paper and add paper to beaker. Add 5 mL alcohol and break up sample with glass rod. Slowly add 200 mL  $\text{HCl}$  while stirring vigorously. Heat to bp on steam bath. Boil 2–3 min and immediately transfer thru funnel to 1 L vol. flask. Complete transfer with 200 mL and 150 mL portions hot  $\text{HCl}$ . Warm flask on steam bath and shake vigorously 3–4 min. Rinse beaker with 450 mL  $\text{H}_2\text{O}$ , add to flask, and mix thoroly. Cool to room temp., dil. to vol. with  $\text{HCl}$ , and mix thoroly. Let undissolved material settle and coagulate. Filter portion thru double layer of

24 cm Whatman No. 12, or equiv., folded paper, discarding first 50 mL. Make appropriate dilns with HCl (55+45) to obtain Zr concn of 40–100 µg/mL. Pipet 5 mL into 100 mL vol. flask, and proceed as in 35.021, beginning "Add to each flask 10.0 mL alizarin red . . ."

% Zr in intact can contents =  $(C/W_s) \times (W_c/W_i) \times (F/10^4)$ ,  
where  $C$  = µg Zr/100 mL read from std curve;  $W_s$ ,  $W_c$ , and  $W_i$  = g sample, prepd conc., and intact can contents, resp.; and  $F$  = appropriate diln factor.

#### Boric Acid (6)—Official Final Action

##### 35.024 Preparation of Ion Exchange Column

Provide glass tube 58 cm long × 2 cm diam. (23 × 0.75") with stopcock and outlet tube. Tamp 3 cm glass wool plug into bottom of tube, fill tube with H<sub>2</sub>O, and add Amberlite IR-120(H) ion exchange resin slowly to form 20 cm column. Wash with HCl (1+9) and then with 50 mL portions H<sub>2</sub>O until effluent gives neg. Cl test.

Regenerate after use by transferring accumulated resin from number of detns to large glass tube and washing with HCl (1+9) until effluent gives neg. test for adsorbed cations, e.g., Zn, Al. Then remove HCl from resin by washing with H<sub>2</sub>O until effluent gives neg. Cl test.

##### 35.025 Determination

Place sample contg 50–200 mg H<sub>3</sub>BO<sub>3</sub> in 250 mL casserole, add 2 drops phthln, and make alk. with 10% NaOH soln. Evap. to dryness on steam bath under gentle air current, dry residue 1 hr at 140° in oven, and ash 1 hr at 550°. Cool to room temp., add ca 50 mL hot H<sub>2</sub>O, acidify cautiously with HCl, and filter hot soln thru quant. paper into 250 mL beaker. Wash paper with little hot H<sub>2</sub>O and reserve filtrate (may be slightly cloudy).

Transfer paper to same casserole and make alk. by wetting with ca 10 mL H<sub>2</sub>O and few drops 10% NaOH soln. Evap. to dryness on steam bath, dry 1 hr at 140°, and ash 2 hr at 550°. Cool, add ca 50 mL hot H<sub>2</sub>O, acidify with HCl, and filter into reserved filtrate. Wash casserole and paper thoroly with hot H<sub>2</sub>O, and discard paper. (Total vol. soln should be ca 200 mL.)

Cool soln; add NH<sub>4</sub>OH until barely alk. to litmus paper or until flocculent ppt appears. Reacidify with HCl until slightly acid to litmus paper or until ppt just redissolves. Pass soln thru ion exchange column into 1 L flask at rate requiring 10–15 min for passage. Follow sample soln with several 50 mL portions H<sub>2</sub>O until effluent is only slightly acid to pH test paper. Add 5 drops Me red, 2.091(b), make alk. with freshly prepd 10% NaOH soln, and then barely acid with HCl.

Connect flask to H<sub>2</sub>O-cooled reflux condenser and boil 5 min. Wash down condenser with little H<sub>2</sub>O and cool soln to room temp. under running H<sub>2</sub>O. Neutze to Me red with 0.1N NaOH, 50.034; add 4–5 g mannitol and ca 0.5 mL phthln. Titr. with 0.1N NaOH to pink color, add more mannitol, and if pink disappears, continue titrn until it reappears. Repeat addn of mannitol until there is no further change in color.

Det. blank as follows: To ca 350 mL H<sub>2</sub>O add vol. of freshly prepd 10% NaOH soln equal to that required to neutze sample after passing thru column. Barely acidify with HCl and proceed as above, beginning "Connect flask to H<sub>2</sub>O-cooled reflux condenser . . ." Subtract blank titrn from sample titrn and calc. H<sub>3</sub>BO<sub>3</sub> content of sample. 1 mL 0.1N NaOH = 0.00618 g H<sub>3</sub>BO<sub>3</sub>.

##### 35.026 Chlorides (7)—Official Final Action

Pipet aliquot of sample soln, 35.014, contg ca 100 mg Cl into 250 mL beaker. Dil. to 150 mL with H<sub>2</sub>O, neutze to litmus with NH<sub>4</sub>OH (1+1), and acidify with 1 mL HNO<sub>3</sub> (1+1). If any undis-

solved ppt remains, add more HNO<sub>3</sub> (1+1) until clear soln is obtained. Add dropwise, stirring constantly, slight excess of 0.1N AgNO<sub>3</sub>. (Excess should be ≤5 mL.) Pptn and succeeding operations must be carried out in subdued light. Heat mixt. to 90–95° and stir until ppt coagulates. Let ppt settle; add 1–2 drops 0.1N AgNO<sub>3</sub> to supernate to ensure presence of excess Ag. Let mixt. stand 1–2 hr in dark.

Decant thru tared gooch, wash ppt 2–3 times with 0.01N HNO<sub>3</sub> by decantation, and finally transfer ppt to gooch with 0.01N HNO<sub>3</sub>. Continue washing ppt with 0.01N HNO<sub>3</sub> until washing gives neg. test for Ag when 1 drop 0.1N HCl is added. Complete washing by removing most of the HNO<sub>3</sub> with two 10 mL portions H<sub>2</sub>O. Dry crucible 2 hr at 120–130° and weigh. Repeat drying to const wt (0.2 mg). Wt AgCl × 0.2474 = wt Cl.

##### 35.027 Sulfates (7)—Official Final Action

Pipet aliquot of sample soln, 35.014, contg ca 100 mg sulfate into 600 mL beaker. Dil. to 350 mL with H<sub>2</sub>O, neutze to litmus with NH<sub>4</sub>OH (1+1), and acidify with 2 mL HCl. If any undissolved ppt remains, add more HCl until soln is clear.

Heat 50 mL 1% BaCl<sub>2</sub> soln almost to bp and add rapidly with stirring to sulfate soln which has also been heated to near bp. Let ppt settle, and add little BaCl<sub>2</sub> soln to ensure excess of Ba. Let mixt. stand 1–2 hr on steam bath. Decant thru tared gooch, wash ppt 4–5 times with small portions of warm H<sub>2</sub>O by decantation, and finally transfer ppt to gooch with warm H<sub>2</sub>O. Continue washing ppt with warm H<sub>2</sub>O until washing gives neg. test for Cl. Dry crucible 2 hr at 110–120° and weigh. Repeat drying to const wt (0.2 mg). Wt BaSO<sub>4</sub> × 0.4116 = wt sulfate.

#### Hexachlorophene (8)—Official Final Action

##### 35.028 Apparatus

(a) *Chromatographic equipment.*—Insert 2 cm plug of glass wool in bottom of tube 55 cm long × 2.5 cm od with constricted tip 2.5 cm long and 8 mm od. Provide with brass tamper of diam. slightly smaller than id of tube, and fittings, including pressure gage, for applying pressure to top of column.

(b) *Spectrophotometer.*—Capable of isolating band ≤5 nm in region 220–360 nm.

##### 35.029 Reagents

(a) *Silanized Celite.*—Weigh ca 700 g Celite 545 into 4 L beaker, add 3 L HCl (1+4), and stir thoroly. Heat on steam bath several hr, stirring occasionally. Filter slurry thru buchner under vac. and wash with H<sub>2</sub>O until washings are Fe- and Cl-free. Suck dry, transfer to beaker, and dry ca 15 hr at 135°. Transfer ca 150 g dried Celite to crystg dish, and let stand in air 30 min. In well ventilated hood, pour 25 mL GE SC-77 Dri-Film (General Electric Co., 1 River Rd, Schenectady, NY 12305) into bottom of large glass desiccator. Place dish contg Celite on porcelain support in desiccator, and let stand in closed desiccator 4 hr. Remove dish, and let stand in hood until residual HCl dissipates.

(b) *Immobile solvent.*—Mix equal vols CCl<sub>4</sub> and *n*-heptane.

(c) *Eluting solns.*—In sep. 250 mL vol. flasks, add 1 mL HCl to 25, 87.5, and 150 mL alcohol and dil. each to vol. with H<sub>2</sub>O (10, 35, and 60% alcohol, resp.).

(d) *Hexachlorophene std solns.*—(1) *Stock soln.*—0.6 mg/mL. Accurately weigh ca 60 mg hexachlorophene USP and dil. to vol. in 100 mL vol. flask with acidified 60% alcohol, (c). (2) *Working std solns.*—Dil. 5, 10, and 20 mL aliquots stock soln to 100 mL with acidified 60% alcohol, (c) (0.03, 0.06, and 0.12 mg/mL).

## 35.030

**Preparation of Sample**

(a) *For products containing sulfated surface-active agents.*—Accurately weigh, in weighing bottle, ca 1 g sample and transfer quant. to 250 mL r-b flask with 75 mL 20% alcohol. Add 10 mL HCl and few boiling chips, attach H<sub>2</sub>O-cooled condenser, and reflux 15 min. Cool to room temp. and transfer to 250 mL separator with ca 25 mL H<sub>2</sub>O. Rinse flask with 30 mL CHCl<sub>3</sub> and transfer to separator. Shake well and drain CHCl<sub>3</sub> into another 250 mL separator. Rinse beaker with two addnl 30 mL portions CHCl<sub>3</sub>, ext aq. soln with each, and combine CHCl<sub>3</sub> exts in 250 mL separator. Wash combined exts with 10 mL H<sub>2</sub>O acidified with HCl, and filter thru CHCl<sub>3</sub>-wetted plug of cotton in powder funnel into 250 mL beaker. Wash cotton with 20 mL CHCl<sub>3</sub>, and evap. CHCl<sub>3</sub> to ca 10 mL on steam bath under air current. Complete evapn to dryness at room temp. under air current.

(b) *For products not containing sulfated surface-active agents.*—Accurately weigh, in weighing bottle, ca 1 g sample and transfer quant. to 250 mL separator with 40 mL warm H<sub>2</sub>O. Acidify with HCl, and ext with three 30 mL portions CHCl<sub>3</sub>. Wash combined CHCl<sub>3</sub> exts with 10 mL H<sub>2</sub>O acidified with HCl, and continue as in (a), beginning, "... and filter thru CHCl<sub>3</sub>-wetted plug ..."

## 35.031

**Isolation of Hexachlorophene**

Weigh two 12 g portions silane-treated Celite. To 1 portion in 250 mL beaker, add 7 mL CCl<sub>4</sub>-*n*-heptane (1+1), mix well, and pack mixt. gently but firmly with tamper into chromatgc tube in ca 4 g portions.

To residue from 35.030(a) or (b), add 7 mL CCl<sub>4</sub>-*n*-heptane (1+1), and stir well to dissolve or disperse residue. Add the second 12 g portion silane-treated Celite, stir thoroly, and pack mixt. into tube as before. Wipe beaker, stirring rod, and tamper with small piece of glass wool and lightly tamp it on top of completed column.

Elute column with 100 mL acidified 10% alcohol, then with 200 mL acidified 35% alcohol, and finally with 250 mL acidified 60% alcohol. Maintain flow at ca 2 mL/min with aid of air pressure and do not permit level of eluting liqs to fall below glass wool plug. Collect two 100 mL portions and then 50 mL portions in vol. flasks. Hexachlorophene should elute with acidified 60% alcohol.

## 35.032

**Determination**

Add 1 drop HCl to each eluate in vol. flasks and obtain spectra over 220–360 nm in 1 cm cell against corresponding eluting soln. If necessary, dil. with corresponding eluting soln. Obtain spectra of working std solns similarly.

From curves, identify eluates contg hexachlorophene. Calc. hexachlorophene in each eluate by comparing *A* at 297 nm of sample with that of std, using straight line background correction. Add amts in eluates to obtain amt in sample.

**Methenamine (9)—Official Final Action**

## 35.033

**Reagent**

*Borax-carbonate soln.*—Dissolve 5.0 g Na<sub>2</sub>CO<sub>3</sub> and 4.0 g Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O in 100 mL H<sub>2</sub>O.

## 35.034

**Determination**

Pipet aliquot of sample soln, 35.014, contg 150–200 mg methenamine into 500 mL r-b flask and dil. to 30 mL with H<sub>2</sub>O. Neutze to litmus with either NaOH soln or dil. H<sub>2</sub>SO<sub>4</sub>; then acidify with 1 mL H<sub>2</sub>SO<sub>4</sub>. Connect flask to H<sub>2</sub>O-cooled condenser and reflux 30 min to hydrolyze methenamine. Dil. to 175 mL by

adding H<sub>2</sub>O thru top of condenser, and disconnect condenser. Connect flask thru Kjeldahl trap to efficient straight-wall condenser and distil into 200 mL vol. flask contg 10 mL freshly prepd 10% NaHSO<sub>3</sub> soln. Continue distn until residual vol. is ca 5 mL, taking care to avoid charring.

Wash down condenser with little H<sub>2</sub>O and cool distillate to room temp. Dil. distillate to vol. with H<sub>2</sub>O, mix well, and let stand 30 min. Pipet 20 mL aliquot into wide-mouth 250 mL erlenmeyer, add 3–4 mL starch indicator, 6.005(f), and destroy excess bisulfite with ca 1*N* I soln. Carefully adjust to starch-I end point with 0.5% NaHSO<sub>3</sub> soln and 0.05*N* I. Dil. to 50 mL with H<sub>2</sub>O, add 10 mL borax-carbonate soln, and titr. with 0.05*N* I to permanent blue. 1 mL 0.05*N* I consumed in alk. titrn = 0.5841 mg methenamine.

**Phenolsulfonates—Official Final Action**

## 35.035

**★ Bromination Method (9) ★**

See 35.025–35.026, 11th ed.

**Spectrophotometric Method (10)**

## 35.036

**Apparatus and Reagents**

(a) *Spectrophotometer.*—See 35.028(b).

(b) *Zinc phenolsulfonate std soln.*—10 mg/L in ca 0.1*N* NaOH. Dissolve 100 mg Zn phenolsulfonate, NF XI (equiv. to 62.67 mg phenolsulfonic acid), in 100 mL H<sub>2</sub>O. Dil. 10 mL aliquot to 100 mL with H<sub>2</sub>O. Pipet 10 mL aliquot into 100 mL vol. flask, add 4 mL freshly prepd 10% NaOH soln, and dil. to vol. with H<sub>2</sub>O.

## 35.037

**Determination**

(a) *In presence of sulfated surface-active agents.*—Accurately weigh sample contg 5–10 mg phenolsulfonic acid into 250 mL erlenmeyer. Add 10 mL H<sub>2</sub>O and 2 mL HCl, connect to H<sub>2</sub>O-cooled condenser, and reflux 0.5 hr. Cool to room temp., transfer quant. to 100 mL separator with 20 mL H<sub>2</sub>O, and proceed as in (b), beginning "... ext with three 30 mL portions CHCl<sub>3</sub>."

(b) *In absence of sulfated surface-active agents.*—Accurately weigh, in weighing bottle, sample contg 5–10 mg phenolsulfonic acid. Transfer quant. to 100 mL separator with aid of 30 mL H<sub>2</sub>O. Acidify with HCl and ext with three 30 mL portions CHCl<sub>3</sub>. Discard CHCl<sub>3</sub> exts. Filter aq. soln thru moistened quant. paper into 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Pipet 10 mL aliquot into 100 mL vol. flask, neutze to litmus paper with freshly prepd 10% NaOH soln, add 4 mL excess, and dil. to vol. with H<sub>2</sub>O. Det. *A* of sample soln and *A'* of std soln at 253 nm in 1 cm cells, using 0.1*N* NaOH as blank.

$$\% \text{ phenolsulfonic acid} = C \times A / [10 A' \times (\text{g sample})],$$

where *C* = concn phenolsulfonic acid (mg/L) in std soln.

**35.038 Urea (7)—Official Final Action**

Pipet aliquot of sample soln, 35.014, contg 50–100 mg urea into 100 mL r-b flask. Acidify with HCl, adding 0.5 mL excess. Immerse flask in steam bath and evap. to dryness. Add 10 g cryst. MgCl<sub>2</sub>·6H<sub>2</sub>O and 1 mL HCl, and connect flask to reflux condenser. Carefully heat mixt. with small flame until MgCl<sub>2</sub> dissolves in its H<sub>2</sub>O of crystn, and reflux slowly 2 hr so that rate of return of liq. from condenser is 9–14 drops/min.

Let soln cool, add H<sub>2</sub>O thru top of condenser, disconnect flask, and if necessary, heat to dissolve solids. Transfer soln to 1 L flat-bottom flask, dil. to ca 400 mL with H<sub>2</sub>O, make alk. with 10% NaOH soln, and distil ca 275–300 mL into suitable portion of 0.1*N* H<sub>2</sub>SO<sub>4</sub> contg several drops of Me red, 50.014(a). Titr. excess acid with ca 0.1*N* NaOH, using more indicator if necessary.

★ Surplus method—see inside front cover.

Stdze the 0.1*N* NaOH against the std 0.1*N* H<sub>2</sub>SO<sub>4</sub>, using Me red as indicator.

Correct for blank by refluxing 10 g cryst. MgCl<sub>2</sub> · 6H<sub>2</sub>O and 1 mL HCl and proceeding as above. 1 mL 0.1*N* H<sub>2</sub>SO<sub>4</sub> = 3.003 mg urea.

### DEPILATORIES

#### 35.039 Sulfides in Powders (71)—Official Final Action

(Caution: See 51.018 and 51.078.)

Pipet 50 mL 0.1*N* As<sub>2</sub>O<sub>3</sub> soln, 50.006, into 250 mL g-s vol. flask. Weigh sample contg <0.12 g sulfide calcd as H<sub>2</sub>S and transfer to flask, washing down any material on sides of flask with H<sub>2</sub>O. Add 20 mL HCl (1+1), stopper immediately, and shake vigorously until sample decomposes. (If sample contains CaCO<sub>3</sub>, slowly add the 20 mL acid thru dropping funnel fitted with rubber stopper to fit flask. Shake gently, letting liberated CO<sub>2</sub> bubble up thru acid. When reaction subsides, drain remainder of acid into flask, remove funnel, stopper flask, and shake vigorously.)

Cool to room temp. and dil. to vol. with H<sub>2</sub>O. Filter thru dry paper into dry flask. Pipet 100 mL filtrate into 300 mL erlenmeyer; add 5 mL starch soln, 2.144(b), and enough I soln to form blue soln. Make alk. with NaHCO<sub>3</sub>, adding 1–2 g excess. Titr. to permanent blue with 0.1*N* I, 50.018. Subtract mL 0.1*N* I consumed in alk. titrn from mL 0.1*N* As<sub>2</sub>O<sub>3</sub> present in aliquot. 1 mL 0.1*N* As<sub>2</sub>O<sub>3</sub> = 0.005411 g CaS or 0.01271 g BaS.

#### 35.059 Qualitative Tests (16)

(a) *General tests.*—KBrO<sub>3</sub> and NaBO<sub>3</sub> are white cryst. salts sol. in H<sub>2</sub>O. Aq. soln of KBrO<sub>3</sub> is slightly acid; of NaBO<sub>3</sub>, slightly alk. In flame test, using Pt wire in slightly darkened room, KBrO<sub>3</sub>

★ Surplus method—see inside front cover.

gives reddish violet flame when viewed thru Co glass;  $\text{NaBO}_3$ , typical yellow Na flame. Both compds give following test: Dissolve 0.1 g sample in 10 mL  $\text{H}_2\text{O}$ , acidify with HCl, and add 0.5 g KI. Liberation of I indicates presence of oxidizing agent.

(b) *Confirmatory test for bromate*.—To 1 mL 5% soln of sample in test tube, slowly add 2 mL  $\text{H}_2\text{SO}_4$  with vigorous shaking. Note odor and color of liberated gas. (*Caution*.) Cool test tube, *carefully* add 2 mL  $\text{CS}_2$ , and shake.  $\text{CS}_2$  layer becomes yellow or red if Br is present.

(c) *Confirmatory test for boron*.—Moisten 0.2 g sample in porcelain crucible with 1–2 drops  $\text{H}_2\text{SO}_4$ , add 2 mL MeOH, stir well, and ignite. Green flame indicates presence of B.

★ **Pyrogallol in Hair Dyes (17)** ★  
Official Final Action

**35.060 Qualitative Test**

Reaction with  $\text{NaHSO}_3$ , isolation, and detn of mp. See **35.058**, 11th ed.

**35.061 Colorimetric Method**

Official Final Action

Bromate titrn. See **35.064**, 11th ed.

**Thioglycolate Solutions in Cold Permanent Waves (16)**  
Official Final Action

**35.064 Qualitative Test**

(*Caution*: See **51.018**.  $\text{Cd}(\text{OAc})_2$  is toxic.)

Dil. 2 mL sample to 10 mL with  $\text{H}_2\text{O}$ , acidify with 10% HOAc, add 5 mL excess, and shake well. Add 2 mL 10%  $\text{Cd}(\text{OAc})_2 \cdot 2\text{H}_2\text{O}$  soln, and shake. White gelatinous ppt forms if thioglycolic acid is present. Add excess of  $\text{NH}_4\text{OH}$  (2+3) and shake. Ppt of Cd thioglycolate will dissolve.

**35.065 Quantitative Method**

(Applicable in absence of reducing substances other than thioglycolates)

Pipet sample aliquot contg 250–300 mg thioglycolic acid into wide-mouth 250 mL erlenmeyer. Dil. to 50 mL with  $\text{H}_2\text{O}$ , add 2–3 drops Me red, **2.115(c)**, and make slightly acid with HCl. Add 3–4 mL starch indicator, **6.005(f)**, and titr. with 0.1N I to purple end point. 1 mL 0.1N I = 0.009212 g thioglycolic acid.

**Dithiodiglycolic Acid (20)—Official Final Action**

**35.066**

**Principle**

Soln contg mixt. of thioglycolic (TGA) and dithiodiglycolic (DTDGA) acids is titrd with std 0.1N I soln, which selectively titrs TGA. DTDGA is reduced to TGA in Jones reductor. Resulting total TGA is titrd; increased TGA represents DTDGA.

**35.067**

**Reagents**

(a) *Zinc metal*.—20–30 mesh. Mallinckrodt Chemicals Analytical Reagent grade has been found suitable.

★ Surplus method—see inside front cover.

(b) *Mercuric salt soln*.—2% aq. soln of  $\text{Hg}(\text{NO}_3)_2$  or  $\text{HgCl}_2$ . (*Caution*: See **51.079**.)

**35.068**

**Apparatus**

(a) *Jones reductor*.—Glass tube, 50–65 cm long, 2 cm id, with stopcock, preferably Teflon, and delivery tip extending ca 8 cm below stopcock.

(b) *Magnetic stirrer*.—With glass- or Teflon-covered stirring bar.

**35.069**

**Preparation of Jones Reductor**

Place 300 g Zn in 800 mL beaker; add 300 mL Hg soln and 2 mL  $\text{HNO}_3$ . Stir 10 min with glass rod. Decant supernate and repeat amalgamation with fresh portion Hg soln and 2 mL  $\text{HNO}_3$ . Wash amalgamated Zn 3 times, by decantation, with  $\text{H}_2\text{O}$ . (Zn should have silvery luster.) Maintain  $\text{H}_2\text{O}$  layer over Zn thruout.

Fill tube with  $\text{H}_2\text{O}$ ; then slowly add prepd Zn, draining excess  $\text{H}_2\text{O}$ . Pass 500 mL  $\text{H}_2\text{O}$  thru column, maintaining  $\text{H}_2\text{O}$  layer over Zn.

Det. suitability of reductor as follows: Pass 20 mL  $\text{H}_2\text{O}$  thru column, followed by 200 mL  $\text{H}_2\text{SO}_4$  (1+9), then 100 mL  $\text{H}_2\text{O}$ . Titr. combined washings as in **35.070(c)**. If titrn is >0.2 mL, wash column with addnl  $\text{H}_2\text{O}$ .

Det. reductor efficiency by treating ca 350 mg DTDGA, accurately weighed, in 5 mL  $\text{H}_2\text{O}$  as in **35.070(b)**. Recovery must be ≥97%. Lower recovery indicates unsuitable reductor.

Prepd reductor may be stored 3 months before use, provided amalgamated Zn is always kept covered with  $\text{H}_2\text{O}$ . Prewash column with 200 mL  $\text{H}_2\text{SO}_4$  (1+9) before use after overnight storage.

**35.070**

**Determination**

(a) *Titration 1*.—Pipet sample aliquot contg 350–400 mg TGA and DTDGA into 500 mL Phillips flask contg mag. stirring bar; dil. to 100 mL with  $\text{H}_2\text{O}$ , add 2 drops Me red indicator, **2.115(c)**, and just acidify with  $\text{H}_2\text{SO}_4$  (1+1). Add starch indicator soln, **6.005(f)**, and titr. soln with 0.1N I std soln, **50.018**.

1 mL 0.1N I = 9.212 mg TGA.

(b) *Reduction*.—Arrange reductor column to deliver into 1 L suction flask contg mag. stirring bar. Connect flask to vac. outlet which can be regulated to desired flow rate.

Dil. sample aliquot equal to that used in *Titration 1* with 200 mL  $\text{H}_2\text{SO}_4$  (1+9).

Add 50 mL  $\text{H}_2\text{SO}_4$  (1+19) to column, apply gentle suction, and elute at ca 10 mL/min. When liq. reaches top of amalgam, immediately add dild sample soln, increase vac., and elute at ca 17–20 mL/min. When liq. reaches top of amalgam, rinse sample container with 100 mL  $\text{H}_2\text{SO}_4$  (1+19) in several portions and add to column. Follow with three 100 mL portions  $\text{H}_2\text{O}$  at ca 50 mL/min. Release vac., rinsing column tip into flask with  $\text{H}_2\text{O}$ .

(c) *Titration 2*.—Place suction flask contg reduced sample soln on mag. stirrer; add 5 drops Me red indicator, **2.115(c)**, and set stirrer at medium speed. Add  $\text{NH}_4\text{OH}$  to yellow indicator color (ca 70 mL); then add  $\text{H}_2\text{SO}_4$  (1+1) dropwise just to indicator red color. Stopper flask and place in ice bath. Cool sample soln with min. swirling to ≤25°. Add 5 mL starch indicator, **6.005(f)**, place on mag. stirrer, and titr. with 0.1N I to purple end point.

Perform sep. blank detns for *Titrations 1* and *2* and make appropriate corrections.

mg DTDGA in sample aliquot =  $9.111(N - M)$ ,

where  $M$  = mL 0.1N I from *Titration 1* corrected for blank and  $N$  = mL 0.1N I from *Titration 2* corrected for blank.

## SUNTAN PREPARATIONS

Amyl *p*-Dimethylaminobenzoate (21)  
Official Final Action

35.071

## Apparatus

(a) *Spectrophotometer*.—Cary Model 11 (replaced by Models 14 and 17) recording spectrophtr, or equiv., with 1 cm quartz cells.

(b) *Chromatographic equipment*.—(1) Glass chromatgc tube, 55 cm × 22 mm id with glass wool plug in constricted tip. (2) Brass tamper to fit chromatgc tube. (3) Source of variable air pressure to regulate column elution rate at ca 2 mL/min.

35.072

## Reagents

(a) *Solvent*.—(1) *Immobile solvent*.—*n*-Heptane-CCl<sub>4</sub> (1+1). (2) *Mobile solvents*.—Acidified 50% and 60% alcohol, contg 2 mL HCl/500 mL.

(b) *Silanized Celite*.—See 35.029(a).

(c) *Amyl p-dimethylaminobenzoate*.—0.01 mg/mL. Dil. 10 mg std (available as Escalol 506 from Van Dyk and Co., Inc., Belleville, NJ 07109) to 1 L with NH<sub>4</sub>OH-60% alcohol (1+99).

35.073

## Preparation of Samples

(Caution: See 51.011, 51.040, and 51.056.)

In weighing bottle, weigh sample contg 10–20 mg amyl *p*-dimethylaminobenzoate. Transfer quant. to 250 mL separator with 50 mL H<sub>2</sub>O, slightly acidify with HCl, using test paper, and ext with four 35 mL portions CHCl<sub>3</sub>. Combine exts, wash with 10 mL H<sub>2</sub>O, and filter thru CHCl<sub>3</sub>-washed cotton plug in powder funnel, into 250 mL beaker. Wash cotton with 10 mL CHCl<sub>3</sub>. Evap. to ca 1 mL on steam bath under air jet. Remove beaker from steam bath and continue evapn under air jet until all CHCl<sub>3</sub> has evapd. Reserve prepd residue for chromatgy.

35.074

## Chromatography

(a) *Column preparation*.—Prep. column in 2 layers as in 35.031, par. 1 and 2. (Proper prepn of columns may be checked by eluting known amt of std from column, noting recovery.)

(b) *Elution*.—Elute column first with 100 mL acidified 50% alcohol at 2 mL/min, then with 350 mL acidified 60% alcohol at same flow rate. Collect eluates in consecutively numbered 50 mL vol. flasks. Add few drops NH<sub>4</sub>OH to each flask, mix well, test for alky, and dil. to vol.

35.075

## Determination

Obtain spectra at 220–360 nm for each eluate. For blanks, use corresponding alcohol solns consisting of either NH<sub>4</sub>OH-50% alcohol (1+99) or NH<sub>4</sub>OH-60% alcohol (1+99). Dil. as necessary with NH<sub>4</sub>OH-alcohol solns of proper concn. For quant. detn, obtain spectra of this compd in basic soln, not acid soln. Calc. amt material in each eluate by comparing *A* at 314 nm of sample with std amyl *p*-dimethylaminobenzoate soln in NH<sub>4</sub>OH-60% alcohol (1+99), (c), using straight line background correction.

## VANISHING CREAM (22)

## 35.076 Test for Type of Emulsion—Official Final Action

Dust small amts of finely ground oil-sol. and H<sub>2</sub>O-sol. dyes on sep. portions of sample. If color of oil-sol. dye spreads rapidly, H<sub>2</sub>O-in-oil emulsion is indicated; if color of H<sub>2</sub>O-sol. dye spreads, oil-in-H<sub>2</sub>O emulsion is indicated.

## 35.077 Water—Official Final Action

Transfer 5–20 g sample to erlenmeyer; add 50 mL toluene, few glass beads, and ca 2 g *lump rosin*. Connect flask to Dean and Stark distg tube receiver, and distil until no more H<sub>2</sub>O collects in receiver. Cool, read vol. H<sub>2</sub>O under the toluene at room temp., and from this vol., calc. % H<sub>2</sub>O.

## 35.078 Ash—Official Final Action

Place 2–10 g sample in flat-bottom Pt dish, and remove H<sub>2</sub>O and volatile material by placing dish on steam bath or in 100° oven. Ignite sample at low temp. and finally at 600° to const wt.

35.079 Chloroform-Soluble Material  
Official Final Action

(Caution: See 51.011, 51.040, and 51.056.)

Place 2–10 g sample in separator, add 25–50 mL H<sub>2</sub>O, acidify slightly with H<sub>2</sub>SO<sub>4</sub> (1+9), and ext with successive pprtions CHCl<sub>3</sub>, collecting all exts in second separator. (Usually 4–5 portions CHCl<sub>3</sub>, each ca 35 mL, are enough to remove all CHCl<sub>3</sub>-sol. material.) Wash combined CHCl<sub>3</sub> exts with 10 mL H<sub>2</sub>O, filter thru cotton plug placed in separator stem, and collect filtrate in weighed dish. Shake aq. washing with small vol. of CHCl<sub>3</sub>, and filter this CHCl<sub>3</sub> into dish. Evap. CHCl<sub>3</sub> on steam bath and dry residue for 15 min intervals at 100° to const wt.

## Glycerol—Official Final Action

35.080

## Reagents

(a) *Potassium periodate soln*.—0.02*M*. Dissolve 4.6 g KIO<sub>4</sub> in ca 500 mL hot H<sub>2</sub>O. Dil. to ca 900 mL with H<sub>2</sub>O, cool to room temp., and dil. to 1 L.

(b) *Sodium hydroxide std soln*.—0.02*N*. See 50.034–50.036.

(c) *Bromocresol purple indicator*.—Dissolve 0.1 g bromocresol purple in 100 mL alcohol.

(d) *Propylene glycol*.—Bp 85–86°/10 mm.

(e) *Arsenious oxide soln*.—0.02*N*. Dil. 100 mL 0.1*N* As<sub>2</sub>O<sub>3</sub>, 50.006, to 500 mL with H<sub>2</sub>O.

35.081

## Isolation and Oxidation of Glycerol

(a) *Isolation of glycerol*.—Place 2–10 g sample in separator, add 25–50 mL H<sub>2</sub>O, acidify slightly with H<sub>2</sub>SO<sub>4</sub> (10 g/100 mL), and ext with successive portions CHCl<sub>3</sub>. (Usually 4–5 portions, each ca 35 mL, remove all CHCl<sub>3</sub>-sol. material.) Wash combined CHCl<sub>3</sub> exts with 10 mL H<sub>2</sub>O. Filter aq. soln and wash H<sub>2</sub>O thru cotton plug to remove droplets of CHCl<sub>3</sub>, and collect filtrate in 250 mL vol. flask. Add 3 drops bromocresol purple indicator to filtrate and neutze with CO<sub>2</sub>-free alkali (0.1*N* NaOH is satisfactory), making final adjustment with 0.02*N* NaOH. Dil. almost to vol. with H<sub>2</sub>O, and if necessary, add more alkali to keep soln light but definite purple; then complete diln to vol. and mix.

(b) *Periodate oxidation*.—Transfer aliquot neut. soln, preferably contg 30–40 mg glycerol, to 100 mL vol. flask, and add 50 mL KIO<sub>4</sub> soln. Dil. to vol. with H<sub>2</sub>O and let stand ca 1 hr. Test for excess periodate, which must be present in oxidn mixt., by adding NaHCO<sub>3</sub> and KI to test portion. If excess is present, I is liberated.

35.082

## Determination

(a) *By titration of formic acid*.—(Applicable in absence of substances yielding acid on periodate oxidn.) Transfer 50 mL aliquot of oxidized mixt. to titrn flask, add 10 drops propylene glycol (ca 0.5 mL), mix well, wash down sides of flask with H<sub>2</sub>O,

and let stand 10 min. Add 3 drops bromocresol purple indicator and titr. with NaOH soln to light purple end point. 1 mL 0.02N NaOH = 1.842 mg glycerol.

(b) *From periodate consumed.*—Transfer 20 mL aliquot of oxidized mixt., **35.081(b)**, to titrn flask and dil. with ca 50 mL H<sub>2</sub>O. Add ca 1.0 g NaHCO<sub>3</sub>, 0.5 g KI, and 5 mL starch indicator, **2.144(b)**. Titr. immediately with As<sub>2</sub>O<sub>3</sub> soln to disappearance of blue. Stdze 10 mL KIO<sub>4</sub> similarly. Difference between the 2 titrns represents amt of periodate reduced in 20 mL aliquot taken. To obtain amt of periodate reduced in original aliquot obtained from 250 mL flask, multiply above difference by 5.

1 mL 0.02N As<sub>2</sub>O<sub>3</sub> = 0.4605 mg glycerol.

#### BIOASSAY

##### 35.083 Eye Irritation Test (23)—Official First Action

Use 6 albino rabbits of either sex, weighing 2.0–2.5 kg, randomly selected, for each substance. Facilities must be designed and maintained so as to exclude extraneous materials that might produce eye irritation. Examine both eyes of each animal before testing. Use only animals without defects or eye irritation.

Hold animal firmly but gently until quiet. Instill 0.1 mL test material onto cornea so that it flows into conjunctival sac of 1 eye of each animal by gently pulling lower lid away from eyeball to form cup into which test substance is dropped. Hold lids gently together 1 sec and release animal. Other eye, untreated, serves as control.

Examine eyes grossly or microscopically and record grade of ocular reaction of cornea, iris, and conjunctiva at 24, 48, and 72 hr, and 7 days. After 24 hr observation, further examine eyes after applying fluorescein-impregnated paper strips (Barnes-Hind, Ayerst, etc.). Eyes may be washed with sterile isotonic NaCl soln after 24 hr reading.

Independently grade each portion of eye (cornea, iris, and conjunctiva) without reference to total score, using definitions and color photographs in "Illustrated Guide for Grading Eye Irritation by Hazardous Substances," Superintendent of Documents, Government Printing Office, Washington, DC 20402. (Note: Color photographs in JAOAC **56**, 912–3(1973) do not have correct color. Use photographs in reprints supplied by AOAC, Box 540, Benjamin Franklin Station, Washington, DC 20044.)

Consider animal as exhibiting pos. reaction if test substance produces, at any of the readings, ulceration of cornea (other than fine stippling), or opacity of cornea (other than slight dulling of normal luster), or inflammation of iris (other than slight deepening of folds (or rugae) or slight circumcorneal injection of blood vessels), or if substance produces in con-

junctivae (excluding cornea and iris) obvious swelling with partial eversion of lids or diffuse crimson-red with individual vessels not easily discernible. Basis for irritation is grade  $\geq 1$  for cornea and iris and  $\geq 2$  for redness and chemosis.

Sample is eye irritant if  $\geq 4$  of 6 rabbits have irritation. Sample is not eye irritant if 0 or 1 of 6 rabbits has irritation. For combined parameters, eye is considered irritated if  $\geq 1$  parameter has a grade considered to be eye irritant. If 2 or 3 animals exhibit pos. reaction, repeat test with 6 different animals. Second test is considered pos. if  $\geq 3$  animals exhibit pos. reaction. If only 1 or 2 animals in second test exhibit pos. reaction, repeat test with 6 different animals. In third test, substance is considered irritant if any animal exhibits pos. reaction.

## 36. Drugs: General

### GENERAL DIRECTIONS

#### 36.001 Extraction with Lighter-Than-Water Solvents

Perform preliminary steps directed in method prior to extrn. Ext. aq. soln in separator with specified vols of solv. (ether, pet ether, etc.) by shaking  $\geq 1$  min. Let sep. completely, swirl to remove  $H_2O$  droplets, transfer lower aq. layer to second separator, and decant solv. layer thru pledget of solv.-washed cotton or glass wool in short-stem funnel inserted in neck of third separator. Wash mouth of separator with fine stream of solv. Repeatedly shake aq. soln with addnl portions of solvs until substance sought is extd, using second and first separators alternately for shaking, collecting solvs by filtering into third. If aq. soln is to be further examined, dry cotton pledget in funnel by drawing air thru stem, and wash with 5 mL  $H_2O$  into main aq. ext.

#### 36.002 Purified Diatomaceous (Siliceous) Earth for Partition Chromatography

Celite 545, acid-washed (Johns-Manville Products Corp.), or equiv., is usually suitable for column chromatgy. When interfering materials are present, purify as follows: Place pad of glass wool in base of chromatgc tube  $\geq 100$  mm diam. and add siliceous earth to ht ca 5 times diam. Add vol. HCl equal to ca  $\frac{1}{3}$  vol. of earth, and let percolate. Wash with MeOH, using small vols at first to rinse walls of tube, and then until washings are neut. to moistened indicator paper. Extrude into shallow dishes, heat on steam bath to remove MeOH, and dry at  $105^\circ$  until material is powdery and MeOH-free. Store in tightly closed containers.

#### Sampling (1)—Official Final Action

Methods for drugs involve analysis of sample portions stated: individual dosage form or fraction of composite, depending on information needed. Implication of results depends upon sampling procedure used.

#### 36.003 I. Tablets and Pills

Methods described below are typical random sampling schemes designed for obtaining analysis representative of particular lot of tablets or pills.

(a) *Bulk lots*.—Mix lot thoroly without mutilating contents. Count, weigh, and thoroly powder  $\geq 100$  units. Calc. av. wt/unit.

(b) *Containers of 1000 or more units*.—Open and cautiously mix contents without mutilation. Count, weigh, and powder  $\geq 30$  units selected at random.

(c) *Containers of 100–500 units*.—Remove from one container  $\geq 20$  units selected at random, weigh, and powder.

#### 36.004 II. Soft Capsules

Count and weigh  $\geq 20$  capsules and det. gross wt/capsule. Open capsules and transfer as much of contents as possible to weighing bottle. Clean capsules (cutting in 2 if necessary) and wash by agitating with alternate portions of alcohol and ether. (Few drops of HOAc mixed with alcohol aids cleaning.) Remove ether before fan or air blast. Deduct wt cleaned, empty capsules from gross wt, and calc. av. net contents.

#### 36.005 III. Ampuls

Before opening ampuls, dislodge any liq. in neck. With file, or other suitable instrument, mark level of liq. on neck. Open each near tip, transfer bulk of contents to small flask, and mix. To det. vol. contents, wash and dry empty ampuls, and fill to mark with  $H_2O$  from buret or graduated pipet.

### SOLVENTS

#### Acetone and Isopropyl and Ethyl Alcohols

#### 36.006 ★ Qualitative Tests (2)—Official Final Action ★

Acetone, in absence of other ketones, is identified as 2,4-dinitrophenylhydrazone, mp  $128^\circ$ . Alcohols, if present at  $>5\%$ , are concd by distn, dried with  $Na_2SO_4$ , and identified as 3,5-dinitrobenzoates: isopropyl, mp  $122^\circ$ ; Et,  $92^\circ$ . For lower concns, acetone is removed by refluxing with alk. paraformaldehyde. Dstd alcohols are oxidized to acetone, pptd by dinitrophenylhydrazone to confirm isopropanol, and to HOAc, forming colored complex with La to confirm EtOH. If acetone and isopropanol are absent, EtOH is detected by iodoform reaction. See **36.006–36.010**, 12th ed.

#### Gas Chromatographic Method (3)—Official Final Action

(Applicable to liq. prepn contg ethanol with isopropanol or acetone or individual compds)

#### 36.007

#### Reagents and Apparatus

(a) *Ethanol std stock soln*.—(1)  $2\%$  (v/v).—Dil. 5.0 mL absolute alcohol to 250 mL with  $H_2O$ . (2)  $0.2\%$  (v/v).—Dil. 10.0 mL soln (1) to 100 mL with  $H_2O$ .

(b) *Isopropanol std stock soln*.— $2\%$  (v/v). Dil. 5.0 mL isopropanol to 250 mL with  $H_2O$ .

(c) *Acetone std stock soln*.— $2\%$  (v/v). Dil. 5.0 mL acetone to 250 mL with  $H_2O$ .

(d) *Acetonitrile internal std stock soln*.— $2\%$  (v/v). Dil. 5.0 mL  $CH_3CN$  to 250 mL with  $H_2O$ .

(e) *Gas chromatograph*.—With 1.8 m (6')  $\times$  4 mm id glass column, packed with 80–100 mesh Porapak Q (Waters Associates, Inc.) and H flame ionization detector. Approx. operating conditions: temps ( $^\circ$ )—column 135, detector 155, injection port 165; N carrier gas flow rate 120 mL/min.  $CH_3CN$  peak should elute in 5 min. Adjust H and air flow rates and electrometer sensitivity so that 5  $\mu$ L  $0.2\%$  EtOH std soln gives 50–70% scale deflection.

#### 36.008

#### Preparation of GC Column

Carefully plug column exit with small pad of glass wool. Apply vac. to exit and slowly add packing material thru inlet, tapping very gently to pack firmly. Pack to within 1 cm of area heated by injection port. Plug with glass wool and condition overnight at  $235^\circ$  with slow N stream.

#### 36.009

#### Preparation of Sample

(a) *Ethanol*.—Prep. soln contg ca  $2\%$  (v/v) EtOH by stepwise dilt with  $H_2O$ . Proceed as in **36.010**.

(b) *Isopropanol*.—Prep. soln contg ca  $2\%$  (v/v) isopropanol by stepwise dilt with  $H_2O$ . Proceed as in **36.010**.

★ Surplus method—see inside front cover.

(c) *Acetone*.—Prep. soln contg ca 2% (v/v) acetone by step-wise diln with H<sub>2</sub>O. Proceed as in **36.010**.

If acetone concn is unknown, prep. 50% diln of product with H<sub>2</sub>O, prep. acetone std soln, and inject sample and std as in **36.010**. To det. amt acetone, adjust product and std dilns to give comparable peak hts; % internal std added to the 2 solns should be equal to % acetone present in std soln.

**36.010****Determination**

Pipet 10 mL sample soln into 100 mL vol. flask. Pipet 10 mL each std stock soln needed into sep. 100 mL vol. flask. Pipet 10 mL internal std stock soln into each flask and dil. to vol. with H<sub>2</sub>O.

Inject 5  $\mu$ L sample and std solns, each in duplicate, using 10  $\mu$ L syringe. Approx. retention times of peaks relative to CH<sub>3</sub>CN internal std peak are as follows: EtOH, 0.76; acetone, 1.32; isopropanol, 1.40.

Calc. % EtOH, acetone, or isopropanol in sample as

$$\% C = C' \times (H/H') \times (I'/I) \times f,$$

where  $C$  and  $C'$  = % component in sample and std, resp.,  $H$  = av. sample peak ht or area in sample chromatogram,  $H'$  = av. std peak ht or area in std chromatogram,  $I$  and  $I'$  = resp. values for internal std, and  $f$  = sample diln factor.

**36.011 ★ Ether (4)—Official Final Action ★**

(Not applicable in presence of essential oils)

Dichromate oxidn of aspirated sample. See **32.370–32.374**, 10th ed.

**36.012 ★ Propylene Glycol (5)—Official Final Action ★**

Periodate oxidn of propylene glycol isolated by codistn with cyclohexane. See **36.016–36.017**, 12th ed.

**HALOGENATED COMPOUNDS****Chlorinated Hydrocarbons (6)—Official First Action****36.013****Apparatus**

(a) *Infrared spectrophotometer*.—Double beam, with wavelength range 2–16  $\mu$ m with 1 mm sealed cells.

(b) *Device for filling pipet or buret by pressure*.—Fit 2-hole rubber stopper (No. 1 fits 8 oz medicine bottle) with 1 glass tube extending just thru stopper and with other end attached to tubing for application of pressure. Thru other hole fit straight glass tube extending to bottom of container and attach to other end short piece of rubber tubing to connect to delivery tip of buret or pipet. When not transferring, prevent evapn with pinch clamps.

**36.014****Reagents**

(Caution: See **51.011** and **51.040**.)

(a) *Chloroform std soln*.—Wash CHCl<sub>3</sub> 3 times with H<sub>2</sub>O, and dry with Na<sub>2</sub>SO<sub>4</sub>. Pipet 10 mL dried CHCl<sub>3</sub> into 200 mL vol. flask contg 185 mL alcohol, dil. to vol. with alcohol, and mix. Using air pressure, transfer 20 mL of this soln to 200 mL vol. flask contg 170 mL alcohol (keep tip below surface), dil. to vol. with alcohol, and mix.

(b) *Carbon tetrachloride std soln*.—Prep. as in (a), using dilns of 5 to 200 and 10 to 200 mL.

(c) *Trichloroethylene std soln*.—Redistil HCIC:CCl<sub>2</sub>, collecting fraction boiling at 86–88°. Prep. as in (a), using dilns of 10 to 200 and 10 to 200 mL.

★ Surplus method—see inside front cover.

(d) *Tetrachloroethylene std soln*.—Redistil Cl<sub>2</sub>C:CCl<sub>2</sub>, collecting fraction boiling at 119–121°. Prep. as in (a), using dilns of 10 to 200 and 10 to 200 mL.

(e) *Reference soln*.—Mix 10 mL alcohol with 75 mL 10% sucrose soln and ext with 10, 10, and 5 mL CS<sub>2</sub>. Combine exts in 25 mL vol. flask and dil. to vol. with CS<sub>2</sub>. (CS<sub>2</sub> exts are dry enough to be placed in NaCl cells.) Use in ref. cell for reading both stds and samples.

**36.015****Preparation of Standard Curves**

(Use air pressure to fill pipet or covered buret.)

Transfer 10–30 mL of each std soln to separators contg 5 vols 10% sucrose soln and 10 mL CS<sub>2</sub>, keeping delivery tip just below surface of liq. Quickly stopper separator and ext 1–2 min by very gently inverting 50–60 times/min. (Do not release pressure thru stopcock.) Let layers sep. and drain CS<sub>2</sub> layer into 25 mL vol. flask or stoppered graduate. Repeat extn with 10 and 5 mL CS<sub>2</sub>, combine all exts, and dil. to vol. with CS<sub>2</sub>. (Exts may be held at room temp. overnight if tightly stoppered, but samples and stds must be read on same day.)

Obtain spectrum of each std soln from 2 to 16  $\mu$ m against ref. soln, (e). (Thruout entire series, gain and position of comb adjustments must not be altered.) If desired, obtain % $T$  (or  $A$ ) at wavelengths of interest (see Table **36.01**), making shortened runs of remaining solns, and combining some of them on 1 chart. Det. % $T$  (or  $A$ ) of both peak and baseline; convert each to  $A$ ; and plot  $\Delta A$  against mL std in aliquot taken for extn on linear paper. If % $T$  is preferred, plot original values of % $T$  on semilog paper.

**Table 36.01 Infrared Wavelengths of Chlorinated Hydrocarbons**

Compound	Wavelength, $\mu$ m	
	Peak	Baseline
Chloroform	8.25	7.70–8.70
Carbon tetrachloride	12.80	12.10–13.90
Trichloroethylene	10.77	10.30–11.00
Tetrachloroethylene	11.10	10.50–11.50

**36.016****Preparation of Sample**

(a) *Encapsulated liquids*.—Det. gross wt of representative number of capsules. Open capsules and transfer contents to g-s flask. Weigh dried empty capsules and det. av. net contents. Transfer 1 mL aliquot, using air pressure, to 200 mL vol. flask contg ca 195 mL alcohol (keep tip below surface), dil. to vol. with alcohol, and mix. For CHCl<sub>3</sub>, use soln direct; for CCl<sub>4</sub>, dil. 25 mL to 100 mL with alcohol; for tri- and tetrachloroethylene, dil. 50 mL to 100 mL with alcohol.

(b) *Preparations such as cough sirups*.—Shake well and let bubbles clear before opening container. Take aliquot contg chlorinated hydrocarbon vol. approx. that of std, using alcohol for diln if necessary.

**36.017****Determination**

Transfer aliquot of sample or sample diln to separator contg 5 vols 10% sucrose soln and 10 mL CS<sub>2</sub> (keep tip beneath surface). Proceed as in **36.015**. Det. identity of chlorinated hydrocarbons present by comparison with std spectra and det. amt from std curves.

**Chlorobutanol (1,1,1-Trichloro-2-methyl-2-propanol)****36.018 ★ Gravimetric Method (7) ★****Official Final Action**

Isolation of chlorobutanol by steam distn, if necessary, liberation of ionic Cl by saponification under pressure, and gravimetric detn of Cl as AgCl. See 36.023–36.024, 12th ed.

**Gas Chromatographic and Infrared Method (8)****Official Final Action**

(Caution: See 51.039, 51.040, 51.048, and 51.049.)

**36.019****Reagents**

- (a) *Diatomaceous earth*.—See 36.002.  
 (b) *Chlorobutanol*.—USP. Store over soln satd with both sugar and salt; product contains  $\frac{1}{2}$  mole  $H_2O$  of hydration.  
 (c) *Glass wool*.—Fine; washed with  $CS_2$  and dried.  
 (d) *Dichlorodimethylsilane*.—Dissolve 5 mL in 100 mL toluene. (Caution: Dichlorodimethylsilane is toxic. Avoid contact with skin or eyes. Use effective fume removal device.)

**36.020****Apparatus**

- (a) *Chromatographic tube*.—23 × 400 mm with drip tip small enough to fit into 10 mL vol. flask, and with close-fitting tamping rod.  
 (b) *Infrared spectrophotometer*.—With matched 1 mm path length, liq.-filled NaCl cells.  
 (c) *Gas chromatograph*.—With 1.8 m (6') × 4 mm glass column, packed with Carbowax 6000 on 100–110 mesh Anakrom ABS, H flame ionization detector, and strip chart recorder.

**36.021****Preparation of GLC Column**

Carefully wash inside of column and small amt of glass wool with dichlorodimethylsilane soln, rinse with MeOH, and dry. Slowly sprinkle ca 25 g Anakrom ABS into 400 mL beaker almost filled with  $CCl_4$ . Remove fine particles remaining at surface with vac. line and trap. Decant solv., oven-dry support, and transfer 20.0 g to 500 mL filter flask fitted with trap and stopper. Dissolve 5.0 g polyethylene glycol (Carbowax 6000) in 100 mL toluene, warming if necessary. Add Carbowax soln to flask and apply vac. 5 min, swirling occasionally. Return to atm. pressure and let stand 5 min. Transfer slurry with rapid swirling to buchner fitted with coarse paper. Maintain reduced pressure on funnel 5 min; then dry coated support by spreading on smooth surface. Air dry 1 hr. Oven-dry addnl hr at 90°.

Carefully plug column exit with small pad fine glass wool and thru-hole septum. Apply vac. to exit port and slowly add coated support thru injection port, tapping very gently to pack firmly. Pack to within 1 cm of area heated by flash heater. Plug with fine glass wool and condition ca 3 days at 200° with slow N stream.

**36.022****Preparation of Standard Solutions**

Dissolve ca 0.5 g chlorobutanol.  $\frac{1}{2}H_2O$ , accurately weighed, in 1 mL alcohol and transfer to 100 mL vol. flask with 8 mL alcohol. Dil. to vol. with  $H_2O$ . Using 5 mL aliquots, prep. duplicate diat. earth columns with trap layers as in 36.023. Prep. and elute columns individually. Calc. mg anhyd. chlorobutanol/mL  $CS_2$  =  $C_{hyd} \times 0.9517$ . (Chlorobutanol is appreciably volatile at room temp.; expose to atm. as little as possible.)

**36.023****GLC Determination**

Weigh 3 g diat. earth, add 2 mL 1N HCl, and mix until uniform. Transfer to chromatgc tube plugged with small pad glass wool and tamp moderately tight.

Calc. vol. sample contg ca 25 mg chlorobutanol. Weigh diat. earth equal to 1 g/mL sample. Pipet sample into diat. earth, and mix (ca 1 min) until uniform. Transfer quant. to same column, dry washing with small amt of dry diat. earth, and tamp firmly. Pack as few portions as possible, each portion  $\leq 5$  g diat. earth. Rinse beaker with small portions  $CS_2$  and transfer to column until sample portion is wet with  $CS_2$ . Let each portion sink into column before adding next. Add 20 mL  $CS_2$  to column and collect eluate in 10 mL vol. flask. Rinse column tip with few drops  $CS_2$  (pipet) when 8–9 mL collects. Continue to collect eluate to vol., stopper flask, and mix. This should yield proper concn for either GLC or IR detns. (Tightly stoppered solns of chlorobutanol in  $CS_2$  may be stored overnight.)

Inject, as below, 6  $\mu$ L sample soln and est. concn from std curve.

**36.024****GLC Standard Curve**

Operating conditions: temps (°)—column 135, detector 215, flash heater 230; N flow rate, ca 35 mL/min to elute chlorobutanol in ca 6 min; and H flow rate, 30 mL/min.

Adjust electrometer sensitivity so that 12  $\mu$ g chlorobutanol gives ca 50% deflection. Inject 4, 5, 6, 7, 8, and 9  $\mu$ L of each std eluate from 10  $\mu$ L syringe. Read vol. in syringe before and after injection; take difference as vol. injected. Plot net ( $\Delta$ ) % deflection against  $\mu$ g anhyd. chlorobutanol injected.

**36.025****Preparation of Infrared Standard**

Record spectrum of each std eluate from 9 to 15  $\mu$ m, using quant. instrument settings and  $CS_2$  in ref. beam. Det. av. A of max. at 12.5–12.6  $\mu$ m, using baseline technics with min. ca 9.5 and ca 14.2  $\mu$ m as base. ( $\Delta A$  is linear from 0.5 to 4.5 mg chlorobutanol/mL  $CS_2$ .)

**36.026****Infrared Determination**

Det. A of sample soln at 12.5–12.6  $\mu$ m, as above.

mg Chlorobutanol in sample aliquot = ( $\Delta A$  sample eluate/ $\Delta A$  std eluate) × mg chlorobutanol in 10 mL  $CS_2$  std.

**36.027 ★ Chloroform or Carbon Tetrachloride (9) ★****Official Final Action**

(See 36.013–36.017.)

Decomposition under pressure to inorg. Cl and detn by Volhard titrn. See 36.355–36.357, 11th ed.

**36.028 ★ Tetrachloroethylene in Mixtures (10) ★****Official Final Action**

(See 36.013–36.017.)

Na reduction and detn of total Cl. See 36.434–36.435, 11th ed.

**36.029 ★ Trichloroethylene (11)—Official Final Action ★**

(See 36.013–36.017.)

Reduction under pressure and detn of total Cl. See 36.437–36.439, 11th ed.

**Iodoform (12)—Official Final Action****36.030****Reagents**

(a) *Ammonium thiocyanate std soln*.—0.05N. Stdze against 0.1N  $AgNO_3$ , using equal vol. alcohol and 3 mL  $FeNH_4(SO_4)_2$  soln as indicator.

★ Surplus method—see inside front cover.

(b) *Ferric ammonium sulfate indicator*.—Dissolve 8 g  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

**36.031****Determination**

Accurately weigh ca 0.25 g  $\text{CHI}_3$  and transfer quant. to 200 mL erlenmeyer. Add 40 mL alcohol, swirl gently until  $\text{CHI}_3$  dissolves, filter if necessary, and immediately add 40 mL 0.1*N*  $\text{AgNO}_3$  and 10 mL  $\text{HNO}_3$ . Swirl gently ca 5 min, let stand at room temp. 2–3 hr, and then swirl occasionally as aid in flocculating the Agl. Titr. excess  $\text{AgNO}_3$  with 0.05*N*  $\text{NH}_4\text{SCN}$ , using 3 mL of the  $\text{FeNH}_4(\text{SO}_4)_2$  indicator. 1 mL 0.1*N*  $\text{AgNO}_3$  = 0.01312 g  $\text{CHI}_3$ . Or: Proceed as in **36.032**, last par. beginning "Collect Agl on weighed gooch, . . ."

**36.032 Iodoform in Ointments (13)****Official Final Action**

Transfer ca 2.5 g sample to tared 50 mL beaker and weigh. Add 5 mL  $\text{CHCl}_3$ , stir gently with glass rod, and transfer bulk of undissolved ointment and  $\text{CHCl}_3$  soln to 250 mL g-s flask. Add 5 mL  $\text{CHCl}_3$  to ointment remaining in beaker and stir until dissolved. Add soln to flask and finally wash beaker 3 times, using  $\leq 5$  mL  $\text{CHCl}_3$  each time, and add washings to flask. Or: weigh sample in small, tared glass capsule, drop capsule with contents into 250 mL g-s flask, and add  $\leq 20$  mL  $\text{CHCl}_3$ . (Use glass capsule only in volumetric detn.) Swirl gently until all ointment dissolves. Add 40 mL 0.1*N* alc.  $\text{AgNO}_3$  and swirl to wash down any  $\text{CHI}_3$  that adheres to sides of flask. Slowly add 10 mL  $\text{HNO}_3$  and let stand at room temp. ca 18 hr. Titr. excess of 0.1*N* alc.  $\text{AgNO}_3$  with 0.05*N*  $\text{NH}_4\text{SCN}$ , **36.030(a)**, using 3 mL  $\text{FeNH}_4(\text{SO}_4)_2$  indicator, **36.030(b)**, vigorously shaking mixt. near end of titrn. 1 mL 0.1*N*  $\text{AgNO}_3$  = 0.01312 g  $\text{CHI}_3$ .

For gravimetric detn use ordinary erlenmeyer instead of g-s flask. Weigh ointment base into 100 mL beaker and add  $\text{CHCl}_3$ . After ointment base dissolves, filter thru gooch, using suction. Wash beaker and crucible once with alcohol. Wash crucible several times with  $\text{CHCl}_3$  without suction. Collect filtrate in erlenmeyer and add 40 mL 0.1*N*  $\text{AgNO}_3$  and 10 mL  $\text{HNO}_3$  in small portions. Let mixt. stand 18 hr. Collect Agl on weighed gooch, using suction. Wash with  $\text{H}_2\text{O}$  and then with alcohol. Finally, wash repeatedly with  $\text{CHCl}_3$  without suction. Dry gooch and contents at ca 125° to const wt. 1 g Agl = 0.5590 g  $\text{CHI}_3$ .

**36.033 Iodoform on Gauze (14)—Official Final Action**

Weigh, in tared g-s weighing bottle, sample of  $\text{CHI}_3$  gauze contg ca 1 g  $\text{CHI}_3$ . ( $\text{CHI}_3$  gauze is usually moist and loses wt rapidly when exposed to air.) Transfer to 150 mL beaker, add ca 75 mL alcohol, and stir until  $\text{CHI}_3$  dissolves. Filter into 200 mL

vol. flask, draining alc. soln by pressing on gauze. Wash with four or five 25 mL portions alcohol, filter washings, and finally dil. to vol. with alcohol. Pipet 40 mL aliquot into 200 mL erlenmeyer and immediately add 40 mL 0.1*N*  $\text{AgNO}_3$  and 10 mL  $\text{HNO}_3$ . Proceed as in **36.032**, beginning "... let stand at room temp. ca 18 hr."

**INORGANIC DRUGS****★ Arsenic in Iron-Arsenic Tablets (15) ★****Official Final Action****36.034****Reagent**

*Std soln of potassium bromate (or of iodine)*.—Stdze against pure  $\text{As}_2\text{O}_3$ . (Concn of this soln is matter of choice. 0.5625 g  $\text{KBrO}_3$  dissolved in  $\text{H}_2\text{O}$  and dild to 1 L gives soln that is 0.02021*N*; 1 mL = 1 mg  $\text{As}_2\text{O}_3$ .)

**36.035****Apparatus**

Use either Ramberg-Sjöström As flask, Fig. **36:01A**, consisting of 300 mL Kjeldahl flask provided with special outlet tube connected with flask by means of  $\text{F}$  joint, or 300 mL Kjeldahl flask provided with 13 mm id outlet tube, with constricted tip ca 5 mm, connected with flask by means of rubber stopper, Fig. **36:01B**.

**36.036****Determination**

(Caution: See **51.019**, **51.026**, **51.030**, and **51.078**.)

Weigh and place in flask tablets or pills equiv. to 25 mg  $\text{As}_2\text{O}_3$ , add 10–15 mL  $\text{H}_2\text{O}$ , and let soak 30 min. Add, in small portions at time, 20 mL fuming  $\text{HNO}_3$ , cooling if necessary to prevent loss by frothing. When reaction ceases, carefully add, in small portions at time, 25–28 mL  $\text{H}_2\text{SO}_4$ . Place flask in inclined position on asbestos mat and heat over small flame. When most of  $\text{HNO}_3$  is driven off, and while still heating, drop in 8 mL fuming  $\text{HNO}_3$  thru suitably placed separator and heat over larger flame until  $\text{SO}_3$  evolves. If after cooling, pptd sulfates are not colorless or pale yellow and are not free from gray or black particles, heat contents of flask further with addnl 10 mL fuming  $\text{HNO}_3$ . (All org. matter must be destroyed.)

To cooled mixt. add 30 mL satd  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  soln; heat until fumes of  $\text{SO}_3$  evolve, and to ensure complete destruction of oxalic acid, for 10 min longer over low flame; cool, and add 20 mL  $\text{H}_2\text{O}$  while gently swirling flask. Dry neck of flask over small flame and add 30 g  $\text{NaCl}$ , 5 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  (or 1 g  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ ), 1 g  $\text{NaBr}$ , and 25 mL  $\text{HCl}$ . Mix, and connect delivery tube. If

★ Surplus method—see inside front cover.

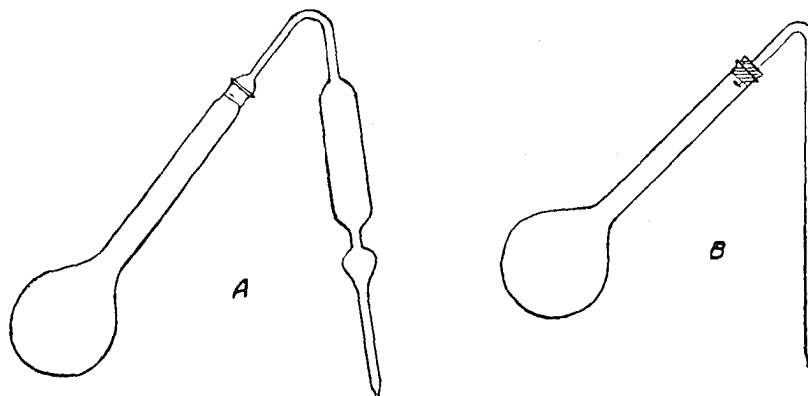

FIG. 36:01—Apparatus for determining arsenic in iron-arsenic tablets

Ramberg-Sjöström app. is used, moisten ground-glass joint with 1 drop  $\text{H}_2\text{SO}_4$ . Fix flask in inclined position with tip of outlet tube ca 1 cm under surface of 150 mL  $\text{H}_2\text{O}$  in erlenmeyer surrounded by ice or by cold  $\text{H}_2\text{O}$ .

Distil at such rate that bend at top of tube becomes warm in 4 min and lower end in ca 8 min from time heat is applied. Discontinue distn after 10 min, but before removing flame, lift distn flask until tip of outlet tube is above  $\text{H}_2\text{O}$  in receiving flask. Let outlet tube drain, remove receiver, and either titr. with std  $\text{KBrO}_3$  soln, using 2 drops Me orange (red of indicator at end point may fade slowly, but color should persist  $\geq 1$  min upon addn of another drop of indicator); or nearly neutze with  $\text{NaOH}$ , add 4–5 g  $\text{NaHCO}_3$ , and titr. with std I soln, **6.005(b)**, using starch indicator, **6.005(f)**.

**36.037 ★ Arsenic in Iron Methylarsenate (16) ★**  
**Official Final Action**

(Caution: See **51.078**.)

Transfer suitable amt of sample (0.2 g, if practicable) to Kjeldahl flask. Add 10 g  $\text{K}_2\text{SO}_4$ , 0.3 g starch, and 20 mL  $\text{H}_2\text{SO}_4$ . Digest over low heat until frothing ceases and continue digestion over slightly higher flame until mixt. is colorless. Cool, and add 20 mL  $\text{H}_2\text{O}$ . Dry neck of flask over small flame, cool contents, and add 30 g  $\text{NaCl}$ , 5 g  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ , 1 g  $\text{NaBr}$ , and 25 mL  $\text{HCl}$ . Distil as in **36.036**. Conduct blank, using same amts of reagents.

**Arsenic in Cacodylate Injections**  
**Differential Pulse Polarographic Method (17)**  
**Official Final Action**

**36.038**

**Apparatus**

(a) *Polarograph*.—Capable of effectively scanning  $-0.15$  to  $-0.9$  v in differential pulse mode. Typical instrument settings: scan rate, 2 mv/sec; scan direction, “—”; range, 1.5 v; initial potential,  $-0.15$  v; modulation amplitude, 50 mv; operation mode, differential pulse; current range, 0.05 ma, or as needed; output offset, as required; display direction, “+”; drop time, 1 sec; low pass filter, off; selector, off; pushbutton, initial; recorder: X-axis, 0.1 v/in., Y-axis, 1 v/in.

(b) *Cells*.—Std cell bottom with satd calomel ref. electrode (SCE), C rod counter electrode, and dropping Hg indicating electrode.

(c) *Pipet*.—100  $\mu\text{L}$  Eppendorf pipet, or equiv.

**36.039**

**Reagents**

(a) *Supporting electrolyte*.—1M  $\text{HCl}$ . Add 82 mL  $\text{HCl}$  to ca 500 mL  $\text{H}_2\text{O}$  in 1 L vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

(b) *Arsenic std soln*.—2.000 mg As/mL. Dissolve 0.2640 g  $\text{As}_2\text{O}_3$ , dried 1 hr at  $105^\circ$ , in ca 25 mL 1N  $\text{NaOH}$  in 100 mL vol. flask, acidify to litmus with 1M  $\text{HCl}$ , and dil. to vol. with  $\text{H}_2\text{O}$ .

**36.040**

**Digestion**

Transfer to 100 mL borosilicate beaker accurately measured vol. of injection, dild if necessary, and contg ca 29 mg Na cacodylate (ca 10 mg As), and add 1.0 g  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and 1 mL  $\text{HNO}_3$ . Heat on hot plate at low heat until  $\text{H}_2\text{O}$  is evapd; then at high heat to dry residue. Complete digestion by placing beaker in furnace at  $450^\circ$  until no brown fumes are evolved (30 min). Remove from furnace and let cool to room temp. Perform blank similarly.

**36.041**

**Reduction of Arsenic**

Add to residue 20 mL 5M  $\text{HCl}$  (2+3) and swirl to dissolve, warming on steam bath, if necessary; then add 5 mL 40%  $\text{HBr}$

and 0.3 g  $\text{H}_2\text{NNH}_2 \cdot \text{H}_2\text{SO}_4$ . Cover beaker with watch glass and place on steam bath 30 min. Cool to room temp., transfer with  $\text{H}_2\text{O}$  to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

**36.042**

**Determination**

Add to polarographic cell 20 mL supporting electrolyte and bubble N thru soln 5 min; then direct gas to sweep over soln. Switch selector to “Cell”, and allow sufficient time for recorder pen to come to rest. Depress “Scan” pushbutton and record polarogram from  $-0.15$  to  $-0.9$  v. Pipet 2 mL of sample soln into cell, bubble N thru soln 1 min, direct gas to sweep over soln, and record polarogram as before, using same instrumental settings. Repeat operations on 2 addnl 100  $\mu\text{L}$  aliquots of std soln. Polarograph blank similarly. Plot std addn curve as follows: mg std added, 0, 0.2, and 0.4, on X-axis and first As peak ht which appears at ca  $-0.37$  v against SCE on Y-axis. Extrapolate linear plot to X-axis to obtain mg As in aliquot. Correct for blank, if necessary. Stds need not be polarographed beyond ca  $-0.60$  v, since anal. peak is at ca  $-0.37$  v against SCE.

**36.043 ★ Arsenic in Sodium Cacodylate (18) ★**  
**Official Final Action**

Digestion with  $\text{H}_2\text{SO}_4$ , distn, and titrn with I. See **36.044**, 12th ed.

**Bismuth Compounds**

**36.044 Gravimetric Method (19)—Official Final Action**

(Applicable in absence of Pb. Caution: See **51.011**, **51.026**, and **51.059**.)

Thoroughly mix sample and weigh 0.5 g into 500 mL Kjeldahl flask. Ignite gently over small flame, using wire gauze under flask, and increase heat towards end. Let cool, add 15–20 mL  $\text{HNO}_3$ , evap. to dryness, and ignite as before until yellow or orange  $\text{Bi}_2\text{O}_3$  is formed. Cool residue and dissolve in 10–15 mL warm  $\text{HNO}_3$ , using few mL 3%  $\text{H}_2\text{O}_2$  if residue does not dissolve readily. Boil off excess  $\text{H}_2\text{O}_2$  and wash into 400 mL beaker with  $\text{H}_2\text{O}$ , rinsing flask well. Dil. to ca 200 mL, make just neut. to litmus with  $\text{NH}_4\text{OH}$ , and add 5 mL  $\text{HCl}$ . Ppt with  $\text{H}_2\text{S}$  completely.

Transfer ppt to filter paper and wash once with  $\text{HCl}$  (5+200) and then several times with  $\text{H}_2\text{O}$ . Dissolve ppt of  $\text{Bi}_2\text{S}_3$  on filter with hot  $\text{HNO}_3$  (1+2). Small residue of S (and HgS if Hg salts are present) usually remains. Neutze filtrate with  $\text{NH}_4\text{OH}$  (2+3) and ppt with 25 mL 20%  $(\text{NH}_4)_2\text{CO}_3$  soln. Conc. to ca 150 mL (by boiling, if desired) and let stand on steam bath 1–2 hr. Collect ppt in previously ignited, weighed gooch, wash with small amt of  $\text{H}_2\text{O}$ , dry, ignite in furnace at ca  $550^\circ$ , and weigh as  $\text{Bi}_2\text{O}_3$ .

**Polarographic Method (20)—Official Final Action**

**36.045**

**Apparatus**

(a) *Polarograph*.—See **20.001**. Capable of scanning 0 to  $-1.0$  v and measuring 0.040  $\mu\text{A/mm}$ .

(b) *Cells*.—Microcell with satd calomel or Hg pool ref. electrode.

**36.046**

**Reagents**

(a) *Supporting electrolyte*.—1M  $\text{HCl}$ . Add 171 mL  $\text{HCl}$  to ca 1 L  $\text{H}_2\text{O}$  in 2 L vol. flask and mix. Cool to room temp., dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

(b) *Gelatin maximum suppressor*.—1 mg/mL. Accurately weigh 100 mg gelatin (Difco Laboratories, No. 0143-01; or Knox Gelatine Inc., Johnstown, NY 12095, unflavored gelatine No. 1)

★ Surplus method—see inside front cover.

into small beaker and dissolve in small amt of H<sub>2</sub>O on steam bath. Transfer quant. to 100 mL vol. flask and dil. to vol. with H<sub>2</sub>O. Prep. fresh daily.

(c) *Bismuth std solns.*—(1) *Stock soln.*—1 mg/mL. Transfer 122.2 mg Bi subcarbonate, equiv. to 100 mg Bi (mg Bi subcarbonate  $\times$  0.8182 (factor derived from primary std) = mg Bi), to 100 mL vol. flask with supporting electrolyte, (a). Dil. to vol. with same soln. (2) *Working soln.*—0.2 mg/mL. Pipet 20.0 mL stock soln into 100 mL vol. flask, add 1.0 mL gelatin max. suppressor, (b), and dil. to vol. with supporting electrolyte, (a). Mix thoroly.

### 36.047

#### Preparation of Sample

(a) *Tablets.*—Det. av. wt/tablet. Grind to pass No. 60 sieve. Quant. transfer amt tablet material contg 10 mg Bi, accurately weighed, to 50 mL vol. flask with aid of 1M HCl, (a). Add 0.5 mL gelatin max. suppressor, (b), and dil. to vol. with 1M HCl. Shake thoroly or use sonic vibrator. Filter thru rapid paper just before polarographic detn.

(b) *Magma, emulsions, and injectables.*—Mix thoroly to disperse suspension. Immediately transfer aliquot contg ca 100 mg Bi to 100 mL vol. flask. Rinse inside of pipet with 1M HCl, (a), and dil. to vol. with same soln. Pipet 10 mL into 50 mL vol. flask, add 0.5 mL gelatin max. suppressor, (b), and dil. to vol. with 1M HCl. Mix thoroly.

(c) *Powder.*—Transfer entire contents of vial, or amt material equiv. to 200 mg Bi for bulk powders or capsules, to 200 mL vol. flask. Wash vial into flask and dil. sample to vol. with 1M HCl, (a). Proceed as for magma, beginning "Pipet 10 mL . . ."

### 36.048

#### Determination

Transfer soln to cell and bubble N thru soln 10 min. Record polarogram from 0 to -1.0 v against satd calomel ref. electrode. Measure ht of diffusion current ( $I_d$ ) at half-wave potential ( $E_{1/2}$ ), and det. Bi concn by comparing wave hts of sample soln with those of std soln polarographed immediately before and after samples. Do all detns at same current sensitivity and consecutively.

$E_{1/2}$  value is qual. identification of Bi.

Calc. concn of Bi as follows:

(a) *Tablets.*—mg Bi/tablet =  $50 \times (I/I') \times C \times (W/W')$ ;

(b) *Magma, emulsions, and injectables.*—mg Bi/mL =  $500 \times (I/I') \times (C/V)$ ;

(c) *Powder.*—mg Bi/mg sample =  $1000 \times (I/I') \times (C/W')$ ;

where  $I$  and  $I'$  = diffusion currents of sample and std, resp.;  $C$  = mg Bi/mL working soln, (c)(2);  $W$  and  $W'$  = av. tablet wt and wt sample taken (mg), resp.; and  $V$  = mL liq. prepn taken.

### 36.049

#### Measurement of Diffusion Current

Measure diffusion current ( $I_d$  at  $E_{1/2}$ ). Draw lines tangent to tops of residual and limiting currents. Draw third line tangent to vertical slope. Measure its length, mark off half-way point at  $I_d/2$ ; then drop perpendicular thru this point and thru abscissa (applied voltage). Diffusion current is perpendicular portion of this line cutting thru limiting current and residual current tangent lines.

#### Calcium and Magnesium (27)—Official Final Action

(Applicable to pharmaceuticals and vitamin-mineral prepn)

### 36.050

#### Reagents

Use H<sub>2</sub>O redistd from glass (preferable) or deionized H<sub>2</sub>O, reagents 1.022(a), (b), (c), and in addn:

(a) *Calcium carbonate.*—Primary std grade, dried 2 hr at 285°.

(b) *Hydroxy naphthol blue.*—Ca indicator (Mallinckrodt Chemical Works No. 5630 in dispenser bottle ready for use, or equiv.). Store in dark and replace after 1 year.

(c) *Calmagite.*—Ca + Mg indicator (Mallinckrodt No. 4283 in dispenser bottle ready for use, or equiv.). Store in dark and replace after 1 year.

(d) *Disodium dihydrogen ethylenediamine tetraacetate (EDTA) std soln.*—0.01M. Dissolve 3.72 g Na<sub>2</sub>H<sub>2</sub>EDTA·2H<sub>2</sub>O (99+ % purity) in H<sub>2</sub>O in 1 L vol. flask, dil. to vol., and mix. Accurately weigh enough CaCO<sub>3</sub> (ca 40 mg) to give ca 40 mL titrn with 0.01M EDTA and transfer to 400 mL beaker. Add 50 mL H<sub>2</sub>O and enough HCl (1+3) to dissolve the CaCO<sub>3</sub>. Dil. to ca 150 mL with H<sub>2</sub>O and add 15 mL 1N NaOH, disregarding any ppt or turbidity. Add ca 200 mg hydroxy naphthol blue indicator and titr. from pink to deep blue end point, using mag. stirrer. Add last few mL EDTA soln dropwise. Molarity EDTA soln = mg CaCO<sub>3</sub>/(mL EDTA  $\times$  100.09).

### 36.051

#### Apparatus

(a) *Titration stand.*—Fluorescent illuminated.

(b) *Ion exchange column.*—Approx. 20  $\times$  600 mm, fitted with coarse porosity fritted glass disk and Teflon stopcock. Place 30–40 g moist Amberlite IR-4B resin (anion exchange resin with high phosphate capacity) from fresh bottle in 600 mL beaker and exhaust with three 250 mL portions 5% Na<sub>2</sub>CO<sub>3</sub> or NaOH. Wash with H<sub>2</sub>O until excess base is removed. Treat resin with three 250 mL portions 5% HCl (3+22), mixing thoroly after each treatment. Rinse with H<sub>2</sub>O until color is removed, and transfer with H<sub>2</sub>O to column. Column is ready for use after draining H<sub>2</sub>O to top of resin column. (Exchange capacity for phosphate is ca 1500 mg; therefore, number of aliquots can be passed thru column before regeneration is necessary. Rinse column with ca 250 mL H<sub>2</sub>O before each use until eluate is colorless.)

### 36.052

#### Preparation of Sample

Transfer 2 g well mixed sample to 100 mL Pt or porcelain dish. Ash at  $\leq 525^\circ$  until apparently C-free (gray to brown). Cool, add 20 mL H<sub>2</sub>O, stir with stirring rod, and add 10 mL HCl cautiously under watch glass. Rinse off watch glass into dish and evap. to dryness on steam bath. Add 50 mL HCl (1+9), heat on steam bath 15 min, and filter thru quant. paper into 200 mL vol. flask. Wash paper and dish thoroly with hot H<sub>2</sub>O. Cool filtrate, dil. to vol., and mix.

### 36.053

#### Determination

Transfer 50 mL aliquot prepd sample to 250 mL beaker and adjust to pH 3.5 with 10% KOH soln added dropwise, using pH meter and mag. stirrer. Pass sample thru resin column (column is in Cl form), collecting effluent in 250 mL vol. flask and adjusting flow rate to 2–3 mL/min. Wash column with two 50 mL portions H<sub>2</sub>O, passing first portion thru at same rate as sample soln and second at 6–7 mL/min. Finally, pass enough H<sub>2</sub>O freely thru column to dil. to vol. Mix thoroly. Pipet two 100 mL aliquots into 400 mL beakers.

*Titration 1 (calcium + magnesium).*—Adjust first aliquot to pH 10 (using pH meter and mag. stirrer) with pH 10 buffer soln, 1.022(a) (ca 5 mL). Add 2 mL 2% KCN soln, 1.022(c), and 200 mg Calmagite indicator, and titr. immediately with 0.01M EDTA soln thru red to deep blue end point, using mag. stirrer.

*Titration 2 (calcium).*—Adjust second aliquot to pH 12.5–13.0 (using pH meter and mag. stirrer) with KOH-KCN soln, 1.022(b) (ca 10 mL). Add 0.100 g ascorbic acid and 200–300 mg hydroxy naphthol blue indicator. Titr. immediately with 0.01M EDTA soln thru pink to deep blue end point, using mag. stirrer.

% Ca =  $Y \times F \times 0.4008 \times 10 \times 100/\text{mg sample}$ ;

% Mg =  $(X - Y) \times F \times 0.2431 \times 10 \times 100/\text{mg sample}$ ;

where  $X$  and  $Y$  = mL EDTA soln from titrns 1 and 2, and  $F$  = molarity EDTA soln/0.01.

### 36.054 Calcium Gluconate (22)—Official Final Action

(Applicable to preps whose aq. solns are neut. and which do not contain salts of other optically active hydroxy acids. *Caution:* See 51.083 and 51.084.)

Weigh two 0.5 g portions Ca gluconate or two 1 g portions powd tablets contg  $\leq 50\%$  of the salt. If chocolate or fatty base is present, wash samples several times on hardened filter with absolute ether and warm residue until ether is driven off.

Transfer each portion to sep. 25 mL vol. flasks, add 15 mL  $\text{H}_2\text{O}$ , and warm until Ca salt dissolves. (Samples contg cocoa will have undissolved residue.) Cool mixt. to room temp.

To one flask (No. 1) add 3.5 g finely pulverized uranyl acetate, stopper, and shake mech. 1 hr. (If agitation is not vigorous enough,  $>1$  hr of shaking may be required.) Let other flask (No. 2) stand. If sample contains chocolate, add little alumina cream, 31.021(b), to each flask. Cool to room temp., dil. flask No. 1 to vol. with uranyl acetate soln (10 g shaken with 95 mL  $\text{H}_2\text{O}$  until satd and then filtered), and flask No. 2 with  $\text{H}_2\text{O}$ . Filter, and polarize each soln in 200 mm tube, using 50 mm tube contg 1.8%  $\text{K}_2\text{Cr}_2\text{O}_7$  soln as light filter. If soln is too dark to read in 200 mm tube, make reading in 100 mm tube and multiply result by 2. If  $X$  = rotation in  $^\circ\text{S}$  of Soln No. 2 and  $Y$  = rotation of Soln No. 1, with 1 g sample: %  $\text{Ca}(\text{C}_6\text{H}_{11}\text{O}_7)_2 = 4.34 \times (Y - X)$ ; and with 0.5 g sample: %  $\text{Ca}(\text{C}_6\text{H}_{11}\text{O}_7)_2 = 8.52 \times (Y - X)$ .

### Calcium, Potassium, and Sodium in Electrolyte Replenishers

#### Atomic Absorption—Flame Photometric Method (23) Official Final Action

(Applicable to Ringer's and Lactated Ringer's Injections)

### 36.055

#### Reagents

(Use  $\text{H}_2\text{O}$  of  $\geq 0.5$  megohms resistivity for all rinsing and diln. Use borosilicate volumetric glassware, including pipets, meeting NBS tolerances. Use  $\geq 4$  mL single transfer pipets for all dilns, except that Class A 5 mL Mohr pipets may be used to complete intermediate and final dilns. Clean all glassware with  $\text{HNO}_3$  (1+3) until washings show no Na at 589 nm when compared with  $\text{H}_2\text{O}$  used in Na detn.)

(a) *Buffer soln.*—0.25M EDTA + 25 mg  $\text{La}_2\text{O}_3/\text{mL}$ . (Required in AA detn of Ca and K only.) Transfer 73.1 g EDTA into 1 L erlenmeyer. Add ca 100 mL  $\text{H}_2\text{O}$ , and shake cautiously with just enough  $\text{NH}_4\text{OH}$  to dissolve. Transfer 25.0 g low-Ca  $\text{La}_2\text{O}_3$  to 500 mL erlenmeyer, add 25 mL  $\text{H}_2\text{O}$ , and very cautiously dissolve with 70%  $\text{HClO}_4$ . Cool both solns. Pour  $\text{HClO}_4$  soln into EDTA soln, and wash mixt. into 1 L vol. flask. Dissolve completely and adjust to pH slightly alk. to *Me orange*, using  $\text{NH}_4\text{OH}$  or 70%  $\text{HClO}_4$ , as needed. Dil. to vol. with  $\text{H}_2\text{O}$ , mix, and store in clean, dry polyethylene or Teflon bottle.

(b) *Calcium std soln.*—10 mg/mL. Dry  $\text{CaCO}_3$  (low in alkalis)  $\geq 2$  hr at  $285^\circ$  (*Caution:* Higher temp. may convert  $\text{CaCO}_3$ , in part, to  $\text{CaO}$ .), cool in desiccator, and transfer 24.975 g to 1 L vol. flask. Add ca 150 mL  $\text{H}_2\text{O}$  and acidify cautiously with 45 mL  $\text{HCl}$  from freshly opened bottle. Cool to room temp., dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Store in clean, dry polyethylene or Teflon bottle.

(c) *Potassium std soln.*—1 mg/mL. Dry  $\text{KCl}$   $\geq 2$  hr at  $500\text{--}600^\circ$ , cool in desiccator, and transfer 1.9070 g to 1 L vol. flask. Dissolve and dil. to vol. with  $\text{H}_2\text{O}$ , mix, and store in clean, dry polyethylene or Teflon bottle.

(d) *Sodium std soln.*—10 mg/mL. Dry  $\text{NaCl}$   $\geq 2$  hr at  $500\text{--}600^\circ$ , cool in desiccator, and transfer 25.420 g to 1 L vol. flask. Dissolve and dil. to vol. with  $\text{H}_2\text{O}$ , mix, and store in clean, dry polyethylene or Teflon bottle.

(e) *Mixed cation std soln.*—(5  $\mu\text{g}$  Ca + 10  $\mu\text{g}$  K + 200  $\mu\text{g}$  Na)/mL. Pipet 10 mL Ca std soln, (b), into 200 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 10 mL this dild soln into 1 L vol. flask, pipet in 10 mL K std soln, (c), and 20 mL Na std soln, (d), dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Store in clean, dry polyethylene or Teflon bottle. Stable  $\geq 1$  month. (Proportionate vols may be prepd.)

### 36.056

#### Instrumental Requirements

(*Caution:* See 51.006 and 51.007.)

Use spectrophtr in AA or flame emission mode. Keep  $A$  readings between 0.100 and 0.820 units, or emission readings between 20 and 95%  $T$  by adjusting sample dilns, if necessary.

Prep. sufficient std solns to bracket sample detns. Readings of all stds must be on linear portion of std curve. Linearity is detd by running intermediate test std which must agree to within 1% of reading indicated by straight line relationship between the bracketing std points.

Spectrophtr must pass following precision test: Read, sequentially, low std, sample, and high std. Repeat twice and average readings of each soln. Results are acceptable if each individual reading differs from av. value for particular soln by  $\leq 1.4\%$ .

### 36.057

#### Determination

(a) *Calcium.*—(1) *For absorption.*—Pipet 5 mL sample and 4 mL buffer soln into 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Prep. "median range std" by diltg mixed cation std soln, including 4.00 mL buffer soln in each 100 mL std soln. Analyze sample and std solns at 422.7 nm, and est. no. and concn of stds needed for final detn as required in 36.056, par. 2. (2) *For emission.*—Proceed as in (1), omitting buffer soln.

(b) *Potassium.*—(1) *For absorption.*—Pipet 5 mL sample to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 10 mL this soln into 50 mL vol. flask, pipet in 2 mL buffer soln, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Prep. "median range std" by diltg mixed cation std soln, including 2.00 mL buffer soln in each 50 mL final soln. Analyze sample and std solns at 766.5 nm, and est. no. and concn of stds needed for final assay as required in 36.056, par. 2. (2) *For emission.*—Proceed as in (1), omitting buffer soln.

(c) *Sodium.*—Pipet 5 mL sample into 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Pipet 4 mL this soln into 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Prep. "median range std" by diltg mixed cation std soln. Analyze sample and std solns at 589.0 nm, and est. no. and concn of stds needed for final assay as required in 36.056, par. 2.

(d) *Calculations.*—Det. concn of each cation from std curve. Calc. concn of each cation as mg Cl salt/100 mL sample.

### ★ Calcium, Phosphorus, and Iron in Vitamin ★ Preparations (24)—Official Final Action

### 36.058

#### Reagents

(a) *Molybdate soln.*—(1) Thoroughly mix 50 g  $\text{MoO}_3$  (99.5–100%) and 140 mL  $\text{H}_2\text{O}$  and dissolve by addn of 72 mL  $\text{NH}_4\text{OH}$  with stirring; (2) dissolve 50 g powd tartaric acid in 140 mL  $\text{H}_2\text{O}$ ; (3) mix 295 mL colorless  $\text{HNO}_3$  with 400 mL  $\text{H}_2\text{O}$ . When solns are cool, pour soln (1) into soln (2) with stirring, and then pour combined solns into soln (3). Keep in warm place (ca  $40^\circ$ )

★ Surplus method—see inside front cover.

overnight, filter thru asbestos, and store in bottle with loosely stoppered, plastic screw cap. When free from phosphates, soln is practically colorless.

(b) *Ammonium nitrate soln.*—Dissolve 500 g  $\text{NH}_4\text{NO}_3$  in  $\text{H}_2\text{O}$  and dil. to 1 L.

(c) *Carbon dioxide-free water.*—Recently boiled and cooled  $\text{H}_2\text{O}$ .

(d) *Sodium hydroxide and hydrochloric acid std solns.*—0.1N. Prep. as in 50.032–50.036, and 50.011–50.013.

### 36.059

#### Determination

Transfer representative portion of well mixed sample contg  $\geq 10$  mg P, 50 mg Ca, and 1 mg Fe to 100 mL Pt or porcelain dish. Ash at  $\leq 525^\circ$  until apparently C-free (gray to brown). Cool, moisten with 20 mL  $\text{H}_2\text{O}$ , break up ash with stirring rod, and cautiously add 10 mL HCl under watch glass. Rinse off watch glass into dish and evap. to dryness on steam bath. Add 50 mL HCl (1+9), heat on steam bath 15 min, and filter thru quant. paper into 200 mL vol. flask. Thoroughly wash filter and dish with hot  $\text{H}_2\text{O}$ , cool filtrate, dil. to vol., and mix.

(a) *Phosphorus.*—Transfer aliquot contg 2–5 mg P to 300 mL erlenmeyer, and dil. to ca 50–60 mL. Add 20 mL  $\text{NH}_4\text{NO}_3$  soln and heat in  $\text{H}_2\text{O}$  bath to  $45\text{--}50^\circ$ . Add 20 mL freshly filtered molybdate soln (this vol. will ppt up to 20 mg  $\text{P}_2\text{O}_5$ ) and let flasks remain in bath 30 min at  $45\text{--}50^\circ$ , swirling contents at ca 5 min intervals. To prevent tipping, weight flask with Pb rings or by other means.

For filtration, use filter tube (so-called carbon filter), ca 28 mm id, fitted with removable, perforated porcelain disk from Caldwell crucible. (Caldwell crucible or gooch may also be used.) Prep. quick filtering pad 3–4 mm thick, using short-fiber asbestos. (Caution: See 51.086.) For convenience in washing and in transferring filter tubes, provide suction flask with rubber stopper having hole somewhat larger than stem of filter tube.

With full suction, filter ppt and wash flask and then filter tube with ca 6 portions cold  $\text{H}_2\text{O}$ , using 150–200 mL total. Test for complete washing by passing 25 mL  $\text{CO}_2$ -free  $\text{H}_2\text{O}$  thru flask and filter tube into clean suction flask. Immediately disconnect suction and add 1 drop each of 0.1N NaOH and phthln, which should yield strong pink color.

Loosen pad and porcelain disk with wire or narrow rod inserted in stem end, and transfer to flask. Place filter tube in neck of flask, dissolve any ppt on walls with measured vol. std alkali, and rinse down filter tube with ca 25 mL  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ . (Enough std alkali must have been added to dissolve ppt.) Stopper flask, swirl, and let stand, mixing occasionally, until yellow ppt completely dissolves. Dil. to ca 75 mL with  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , add 10 drops phthln, and titr. with std acid to complete disappearance of pink, matching end point with another flask contg  $\text{H}_2\text{O}$  and asbestos only. If alkali adheres to fragments of asbestos, making end point uncertain, add slight excess of std acid and complete titrn with std alkali. 1 mL 0.1N NaOH = 0.3086 mg  $\text{P}_2\text{O}_5$ . Subtract alkali consumed in blank detn.

(b) *Calcium.*—Transfer aliquot contg 20–40 mg Ca to beaker, dil. to 100 mL, and proceed as in 3.015. Correct for  $\text{KMnO}_4$  consumed in blank detn.

(c) *Iron.*—Transfer aliquot contg 0.2–0.5 mg Fe to 100 mL vol. flask, add enough HCl (1+9) to yield 2 mL concd acid, and dil. to vol. Proceed as in 14.013(a), beginning "Pipet 10 mL aliquot into 25 mL vol. flask . . ." Det. Fe in sample by comparison with stds prep'd as in 14.012.

### 36.060 ★ Effervescent Potassium Bromide with ★ Caffeine (25)—Official Final Action

KBr is det'd by Volhard titrn; caffeine is det'd by extrn from alk. soln with  $\text{CHCl}_3$  and weighing. See 36.057–36.058, 12th ed.

### Elixir of Five Bromides (26)—Official Final Action

#### 36.061

#### Preparation of Dilution

Transfer 50 mL sample to 1 L vol. flask, dil. to vol., and mix. Measure aliquots of this diln at original temp. of sample.

#### 36.062

#### Determinations

(a) *Ammonium bromide.*—Place 200 mL aliquot of diln in Kjeldahl flask; add small piece of paraffin and excess 10% NaOH soln (ca 5 mL). Distil  $\text{NH}_3$  into excess std acid (40 mL 0.1N usually is enough). Titr. excess acid with 0.1N NaOH, using Me red. 1 mL 0.1N acid = 0.00979 g  $\text{NH}_4\text{Br}$ .

(b) *Calcium bromide.*—Pipet 100 mL aliquot of diln into casserole or Pt dish and evap. to dryness. Ignite at dull red (ca  $525^\circ$ ) until org. matter is thoroly charred. Cool, add 5 mL HCl (1+3) to dissolve Ca salts, filter, and wash well with hot  $\text{H}_2\text{O}$ . Return filter and unoxidized C to casserole or dish and ignite at  $600^\circ$  until residue is white. Treat residue with 5 mL HCl (1+3), filter, and wash with hot  $\text{H}_2\text{O}$ , combining filtrates.

Det. Ca as in 3.015, and reserve filtrate for detn of Na, K, and Li. If 0.1N  $\text{KMnO}_4$  is used, 1 mL = 0.0100 g  $\text{CaBr}_2$ .

(c) *Lithium bromide.*—Dil. filtrate and washings from Ca detn to 200 mL and mix. Evap. 100 mL aliquot to dryness and drive off all  $\text{NH}_4$  salts by heating to faint red (ca  $525^\circ$ ) in Pt dish. Treat residue with little  $\text{H}_2\text{O}$ , filter into Pt dish, add few mL HCl, and evap. to dryness.

Complete conversion of alkali bromides to chlorides by treating residue with  $\text{Cl-H}_2\text{O}$  and evap'g to dryness. Repeat addn and evap'n of  $\text{Cl-H}_2\text{O}$  twice more, or until there is no apparent darkening of soln due to liberation of Br.

Dissolve mixed chlorides in min. amt of cold  $\text{H}_2\text{O}$  (ca 1.5 mL is more than enough for 0.5 g salts), in tall 200 mL beaker. Add 1 drop HCl, and then gradually add 20 mL absolute alcohol, dropping alcohol into center of beaker (not on sides) while rotating soln. (NaCl and KCl should be ppt'd in perfectly uniform granular condition.) In similar manner add 60 mL ether (sp gr 0.716–0.717 at  $25^\circ$ ) and let mixt. stand ca 5 min or until ppt is well agglomerated and supernate is almost clear, rotating mixt. occasionally. Filter with suction thru weighed gooch into erlenmeyer, using bell jar arrangement, washing beaker thoroly with mixt. of alcohol and ether (1+5), and collecting all ppt on gooch with aid of policeman. Thoroly wash ppt on gooch, set crucible aside, and rinse funnel with alcohol-ether mixt. to wash any adhering Li soln into flask contg filtrate. Evap. filtrate to dryness on steam bath, using air current.

Treat residue with 10 mL absolute alcohol, warming if necessary, so that practically all residue dissolves. If slight film remains on bottom and sides of flask, remove with policeman. Then, while rotating soln in flask, add 50 mL ether (sp gr 0.716–0.717 at  $25^\circ$ ), followed by 1 drop HCl. Let stand 30 min, rotating soln frequently. When fine ppt has agglomerated (only very small amt is usually ppt'd), filter into tall beaker with suction thru gooch contg first ppt. Wash combined ppts with the ether-alcohol mixt., taking same precautions as in first pptn. Air dry gooch and contents; then dry in oven, ignite gently, cool, and weigh to obtain combined wt NaCl and KCl. Reserve crucible and contents for K detn.

Evap., on steam bath, ether-alcohol filtrate and washings contg the Li. Dissolve residue in little  $\text{H}_2\text{O}$ , add slight excess of  $\text{H}_2\text{SO}_4$  (1+1), and transfer to weighed porcelain or Pt dish. Evap. as far as possible on steam bath and then gently ignite residue over flame. (By placing dish on triangle over asbestos gauze and using low flame, soln can be evap'd without spattering.) Finally ignite carefully over full flame, cool, and weigh. If charring

★ Surplus method—see inside front cover.

has occurred, repeat ignition with  $\text{H}_2\text{SO}_4$ . Calc. to LiBr, using factor 1.5800.

(d) *Sodium bromide*.—Remove combined KCl and NaCl from gooch by washing with hot  $\text{H}_2\text{O}$ , dil. to 50 mL, and use 5 mL aliquot for detn of Na. Proceed as in 3.028, beginning "... add 100 mL Mg uranyl acetate soln ...". Calc. to NaBr, using factor 0.0688.

(e) *Potassium bromide*.—To 25 mL aliquot of soln of KCl and NaCl, add enough Pt soln (0.105 g  $\text{H}_2\text{PtCl}_6/\text{mL}$ ) to convert KCl and NaCl to  $\text{K}_2\text{PtCl}_6$  and  $\text{Na}_2\text{PtCl}_6$ , and evap. to dryness. Treat residue with 80% alcohol by vol., filter, and wash until excess of  $\text{H}_2\text{PtCl}_6$  and  $\text{Na}_2\text{PtCl}_6$  is removed. Dry filter and ppt, dissolve residue in hot  $\text{H}_2\text{O}$ , and transfer to weighed Pt dish. Evap. on steam bath, dry 30 min in oven at  $100^\circ$ , cool, and weigh as  $\text{K}_2\text{PtCl}_6$ . Calc. to KBr, using factor 0.4898.

(f) *Total bromine*.—Transfer 20 mL of diln to 500 mL flask. Add 100 mL  $\text{H}_2\text{O}$ , 2 mL  $\text{HNO}_3$ , and excess of 0.1N  $\text{AgNO}_3$  (usually 30 mL). Titr. excess  $\text{AgNO}_3$  with 0.1N  $\text{NH}_4\text{SCN}$ , using Fe alum indicator. 1 mL 0.1N  $\text{AgNO}_3 = 0.00799$  g Br.

### 36.063 ★ Elixir of Three Bromides (26) ★ Official Final Action

$\text{NH}_3$  is detd by distn into excess std acid and back titrating; K is detd gravimetrically as  $\text{K}_2\text{PtCl}_6$ ; Na is detd gravimetrically as Na-Mg uranyl acetate; and total Br is detd by Volhard titrn. See 36.061–36.062, 12th ed.

### ★ Hypophosphites in Sirups (27) ★ Official Final Action

(Applicable in absence of phosphates; if phosphates are present, make suitable correction.)

#### 36.064 Method I

Hypophosphites are oxidized to phosphate with  $\text{HNO}_3$ ; phosphate is pptd with molybdate soln; phosphomolybdate is dissolved in  $\text{NH}_4\text{OH}$ , and phosphate is repptd as  $\text{MgNH}_4\text{PO}_4$  which is detd gravimetrically as  $\text{Mg}_2\text{P}_2\text{O}_7$ . Ca is pptd as oxalate and ignited to  $\text{CaSO}_4$  in presence of  $\text{H}_2\text{SO}_4$ . See 36.063, 12th ed.

#### 36.065 Method II

(Not applicable in presence of other reducing agents or of phenolic compds)

Oxdn of hypophosphites with excess std bromate; residual bromate liberates I which is titrd with  $\text{Na}_2\text{S}_2\text{O}_3$ . See 36.064–36.065, 12th ed.

### 36.066 Iodine (28)—Official Final Action

Transfer sample contg  $\leq 0.1$  g iodide (0.05 g is ample) to crucible, preferably Ni. If sample contains only slight amt of org. material, add 1 g starch. Add 2–3 g solid KOH. If sample is solid, add 10–15 mL alcohol before adding KOH. Alkali must be thoroly mixed with sample to prevent loss of I in furnace (either stir, leaving stirring rod in crucible, or heat and swirl on steam bath until KOH is in soln). Dry and char thoroly. (Use as low temp. as possible to prevent loss of I;  $\leq 525^\circ$ .) Ext charred mass with hot  $\text{H}_2\text{O}$ , filter into erlenmeyer, and wash well with hot  $\text{H}_2\text{O}$ .

★ Surplus method—see inside front cover.

Neutze filtrate with  $\text{H}_2\text{SO}_4$  (1+1), make alk. again with 4% NaOH soln, and add 1 mL excess. Heat to bp and slowly add satd  $\text{KMnO}_4$  soln until  $\text{KMnO}_4$  color remains after several min of boiling. Then add ca 0.5 mL excess, continue boiling ca 5 min, and let cool. Add enough  $\text{KMnO}_4$  to completely oxidize all iodide to iodate so that  $\text{KMnO}_4$  color, not brown  $\text{MnO}_2$  color, is present at end of boiling period. Add few mL alcohol and place on steam bath. ( $\text{KMnO}_4$  color should be bleached; if it is not, add little more alcohol.) When ppt has settled, filter, and wash with hot 1%  $\text{NH}_4\text{Cl}$  soln. If filtrate is not clear, digest on steam bath until the  $\text{MnO}_2$  can be retained on filter. After cooling, add 1–2 g KI, acidify with HCl, and titr. with 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ . 1 mL 0.1N  $\text{Na}_2\text{S}_2\text{O}_3 = 0.00277$  g KI, 0.00250 g NaI, or 0.00212 g I.

### 36.067 Iodine Ointment (29)—Official Final Action

(a) *Free iodine*.—Weigh (to 1 mg) ca 2 g ointment, and transfer to 250 mL I flask. Melt on  $\text{H}_2\text{O}$  bath ( $\leq 70^\circ$ ), add 30 mL  $\text{CHCl}_3$ , mix well, and then add 30 mL  $\text{H}_2\text{O}$ . (All of base should be dissolved in  $\text{CHCl}_3$  before  $\text{H}_2\text{O}$  is added.) Titr. with 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , using starch indicator, 6.005(f). Approach end point dropwise, shaking flask vigorously to ensure that all I has been extd from  $\text{CHCl}_3$  layer. 1 mL 0.1N  $\text{Na}_2\text{S}_2\text{O}_3 = 0.01269$  g I.

(b) *Potassium iodide*.—Pour liqs from free I detn, (a), into 500 mL I flask, rinsing flask with 200 mL  $\text{H}_2\text{O}$ , added in several portions. (It is desirable to maintain this vol. within rather narrow limits.) Add 0.5 mL 0.2% alc. *p-ethoxychrysoidin* indicator and 1–4 drops 0.1N NaOH (to neutze). (Aq. layer should now be clear yellow.) Titr. with 0.1N  $\text{AgNO}_3$ , approaching end point dropwise and swirling frequently. ( $\text{AgNO}_3$  soln causes turbidity due to formation of colloidal AgI and development of reddish-brown color similar to that observed in over-titrd Volhard detn. End point, which is produced by 1 drop  $\text{AgNO}_3$  soln, is characterized by flocculation of colloidal AgI and complete disappearance of reddish brown tinge, leaving almost clear, pale yellow supernate.) mL 0.1N  $\text{AgNO}_3 - \text{mL}$  0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , (a) = mL consumed by iodide originally present. 1 mL 0.1N  $\text{AgNO}_3 = 0.0166$  g KI.

### Iron

#### Spectrophotometric Method (30)—Official Final Action

(Applicable to drugs listed in Table 36.02. Rinse all glassware with deionized  $\text{H}_2\text{O}$  before use to avoid Fe contamination from tap  $\text{H}_2\text{O}$ .)

Table 36.02 Conditions for Analysis of Various Iron Preparations

Preparation	Initial Solv.	Diln Solv.	Color Develop. Temp.
Ferrous ammonium sulfate, powder	(1)	$\text{H}_2\text{O}$	Room
Ferrous sulfate, powder, tablets	(1)	$\text{H}_2\text{O}$	Room
Ferrous gluconate, powder, tablets	(1)	$\text{H}_2\text{O}$	Room
Ferrous fumarate, powder, tablets	(1)	$\text{H}_2\text{O}$	Heat
Ferric ammonium citrate, powder	(1)	$\text{H}_2\text{O}$	Heat
Ferric glycerophosphate, powder	(1)	$\text{H}_2\text{O}$	Room
Iron cacodylate, powder, injection <sup>a</sup>	(1)	$\text{H}_2\text{O}$	Heat
Iron peptonate, powder	$\text{H}_2\text{O}$	(2)	Heat
Soluble ferric pyrophosphate, powder	$\text{H}_2\text{O}$	(2)	Room
Ferrous sulfate, elixir	$\text{H}_2\text{O}$	(2)	Room
Iron sorbitex, injection (1.00 mL sample)	$\text{H}_2\text{O}$	(2)	Heat
Iron dextran, injection (1.00 mL sample)	$\text{H}_2\text{O}$	(2)	Heat

Solv. (1) = 100 mL  $\text{H}_2\text{O}$  contg 4 mL HCl, dil. to vol. with  $\text{H}_2\text{O}$

Solv. (2) = 2 mL HCl, dil. to vol. with  $\text{H}_2\text{O}$

<sup>a</sup> For iron cacodylate injection, use sample contg 5–6 mg Fe and use initial diln directly for detn.

**36.068****Principle**

Sample is dissolved in dil. HCl or H<sub>2</sub>O and dild to concn of 3 mg/100 mL. Fe<sup>+2</sup> is detd by complexing with  $\alpha,\alpha'$ -dipyridyl at pH 4.5 and measuring *A* at 523 nm. Total Fe is detd by reducing Fe<sup>+3</sup> to Fe<sup>+2</sup> with ascorbic acid and complexing with dipyrldyl. Fe<sup>+3</sup> is detd by difference.

**36.069****Reagents**

(a) *Dipyridyl soln.*—Dissolve 0.1 g  $\alpha,\alpha'$ -dipyridyl in H<sub>2</sub>O and dil. to 100 mL. Soln is stable up to 4 months if stored in cool, dark place.

(b) *Iron std solns.*—(1) *Stock soln.*—0.3 mg Fe/mL. Accurately weigh ca 0.3 g std Fe powder (99.999%, A. D. Mackay, Inc., 198 Broadway, New York, NY 10038, or equiv.), dissolve in 100 mL H<sub>2</sub>O and 20 mL HCl by heating on steam bath, if necessary, dil. to 1 L with H<sub>2</sub>O, and mix. (Complete soln may require as long as 5 hr heating.) (2) *Working soln.*—0.03 mg/mL. Dil. 50.0 mL stock soln to 500 mL with H<sub>2</sub>O.

(c) *Acetate buffer soln.*—pH 4.5. Dissolve 273 g NaOAc.3H<sub>2</sub>O in H<sub>2</sub>O, add 240 mL HOAc, and dil. to 2 L with H<sub>2</sub>O.

**36.070****Preparation of Sample**

(Complete immediately to avoid oxidn of Fe<sup>+2</sup> to Fe<sup>+3</sup>.)

(a) *Powders.*—Accurately weigh sample contg ca 60 mg Fe, transfer to 200 mL vol. flask, and dissolve and dil. to vol. with initial solv. specified in Table 36:02. Dil. 10.0 mL aliquot to 100.0 mL with specified dildn solv.

(b) *Tablets.*—Accurately weigh portion powd tablets or individual tablets contg ca 60 mg Fe into 200 mL vol. flask, add 100 mL H<sub>2</sub>O and 4 mL HCl, heat on steam bath 30 min (Fe gluconate and FeSO<sub>4</sub> do not require heat; place 5–10 min in ultrasonic bath), cool to room temp., and dil. to vol. with H<sub>2</sub>O. Filter thru Whatman No. 1 paper, or equiv. Dil. 10.00 mL filtrate to 100.0 mL with H<sub>2</sub>O.

(c) *Elixirs, sirups, and injections.*—Pipet sample (use "to contain" pipet and rinse, if sample is viscous) contg ca 60 mg Fe into 200 mL vol. flask, dil. to vol. with H<sub>2</sub>O, and mix. Pipet 10 mL into 100 mL vol. flask, add 2 mL HCl, and dil. to vol. with H<sub>2</sub>O.

**36.071****Determination**

(a) *Ferrous iron.*—Pipet duplicate 10 mL aliquots sample soln (1 as sample blank) and 10 mL working std soln, contg ca 300  $\mu$ g Fe, into sep. 100 mL vol. flasks. Transfer 10 mL reagent blank soln, prepd by dildg 4 mL HCl to 2 L with H<sub>2</sub>O, into fourth 100 mL vol. flask. To all solns, add 15 mL buffer soln and ca 20 mL H<sub>2</sub>O, and mix. To 1 sample soln, std, and reagent blank, add 5 mL dipyrldyl soln. To std soln, add 20–25 mg USP ascorbic acid powder. Dil. all solns to vol. with H<sub>2</sub>O, and mix. Let stand 3 hr.

Record *A* of working std soln, sample soln, and sample blank soln (no addn of dipyrldyl soln) from 700 to 500 nm against reagent blank soln, setting spectrophtr at 0 *A* at 523 nm against reagent blank soln. Use *A* at max., ca 523 nm.

$$\% \text{ Fe in powder} = [(A - A_0)/A'] \times C \times (200/W),$$

where *A*, *A*<sub>0</sub>, and *A'* refer to sample, sample blank, and std, resp.; *C* = concn working std soln in  $\mu$ g/mL; and *W* = mg sample.

$$\text{mg Fe/tablet} = [(A - A_0)/A'] \times C \times (2/W) \times T,$$

where *T* = av. mg/tablet.

mg Fe in original aliquot elixir, sirup, or injection taken for assay =  $[(A - A_0)/A'] \times C \times 2,$

$$\text{mg Fe compd} = (\text{mg Fe} \times \text{MW})/55.85,$$

where MW = molecular wt of Fe compd.

(b) *Total iron.*—Proceed as in (a), adding ascorbic acid to sample, sample blank, and std solns. Develop color 3 hr at room temp. or 1 hr, without delay, on steam bath as specified in Table 36:02, heating before dildg solns to vol. Det. *A* as in (a), and calc. % total Fe or mg/dose or aliquot.

(c) *Ferric iron.*—Fe<sup>+3</sup> = total Fe – Fe<sup>+2</sup>, all expressed in same units.

**Ferrous Sulfate****Semiautomated Method (31)—Official First Action****36.072****Principle**

FeSO<sub>4</sub> in tablets, capsules, or liqs is dissolved in 2% H<sub>2</sub>SO<sub>4</sub>, mixed with 1,10-phenanthroline in acetate buffer to form stable Fe<sup>+2</sup> complex, and *A* is measured in flowcell at 502 nm.

**36.073****Apparatus**

(a) *Automatic analyzer.*—AutoAnalyzer with following modules (Technicon Instruments Corp.: Sampler II with 30/hr (3:1) cam; 2 proportioning pumps (I or II); manifold; colorimeter I, with 15 mm tubular flowcell and matched 502 nm filters, or spectrophtr; compatible recorder (see Fig. 36:02).

(b) *Shaker.*—Wrist action (Burrell Corp., model BT, or equiv.).

(c) *Ultrasonic generator.*—Model 11, 150 watt (Heat Systems-Ultrasonic, Inc., 38 E Mall, Plainview, NY 11803), or equiv.

**36.074****Reagents**

(Use deaerated, deionized H<sub>2</sub>O thruout.)

(a) *1,10-Phenanthroline reagent.*—35 mg/100 mL. Dissolve 350 mg 1,10-phenanthroline.H<sub>2</sub>O in 500 mL H<sub>2</sub>O, dil. to 1 L with H<sub>2</sub>O, and add 10 drops wetting soln, (c).

(b) *Sulfuric acid.*—2% (w/v). Dil. 11.4 mL H<sub>2</sub>SO<sub>4</sub> to 1 L with H<sub>2</sub>O.

(c) *Acetate buffer.*—pH 4.6–4.7. Dissolve 136.08 g NaOAc in mixt. of 57 mL HOAc and 500 mL H<sub>2</sub>O. Dil. to 2 L with H<sub>2</sub>O, add 20 drops of wetting soln, (d), and mix well.

(d) *Wetting soln.*—30% (w/v) polyoxyethylene lauryl ether in H<sub>2</sub>O (Brij-35, Technicon No. T21-0110).

(e) *Iron std soln.*—60 mg Fe/100 mL. Accurately weigh ca 60 mg Fe wire and transfer to 100 mL vol. flask. Add 10 mL H<sub>2</sub>O and 1.3 mL H<sub>2</sub>SO<sub>4</sub>, heat on steam bath until dissolved, and dil. to vol. with H<sub>2</sub>O.

**36.075****Preparation of Sample**

Place individual tablet or capsule, liq. aliquot, or weighed composite in accurately measured vol. 2% H<sub>2</sub>SO<sub>4</sub> to give Fe concn of 0.6 mg/mL. Use ultrasonic generator to disintegrate solid dosage formulations. After complete disintegration, agitate 15 min on mech. shaker. Let settle 2 hr.

**36.076****Analytical System**

Sample is withdrawn and dild with air-segmented stream of H<sub>2</sub>O in double mixer, resampled, and mixed with acetate buffer. 1,10-Phenanthroline reagent is added and, after mixing in double mixer, soln is debubbled and passed thru 15 mm flowcell, where *A* is measured at 502 nm.

## 36.077

**Start-Up and Shut-Down Operations**

Place all lines in resp. solns and pump until steady baseline is obtained (ca 15 min). To shut down system, place all lines in H<sub>2</sub>O and pump 10 min. Remove lines from H<sub>2</sub>O reservoir and pump system dry. If irregular bubble pattern occurs during sample run, pump soln contg 10 drops wetting soln/L H<sub>2</sub>O thru system ca 5 min before finally flushing with H<sub>2</sub>O for shut-down.

## 36.078

**Determination**

Fill sample cups in following order: 3 cups std soln, 5 cups sample soln, 1 cup std soln, 5 cups sample soln, etc., ending with 3 cups std soln. (First 2 cups of std soln are used to equilibrate system, but are not included in calcs.) Start Sampler II. After last cup has been sampled, let system operate until steady baseline is obtained. Draw tangent to initial and final

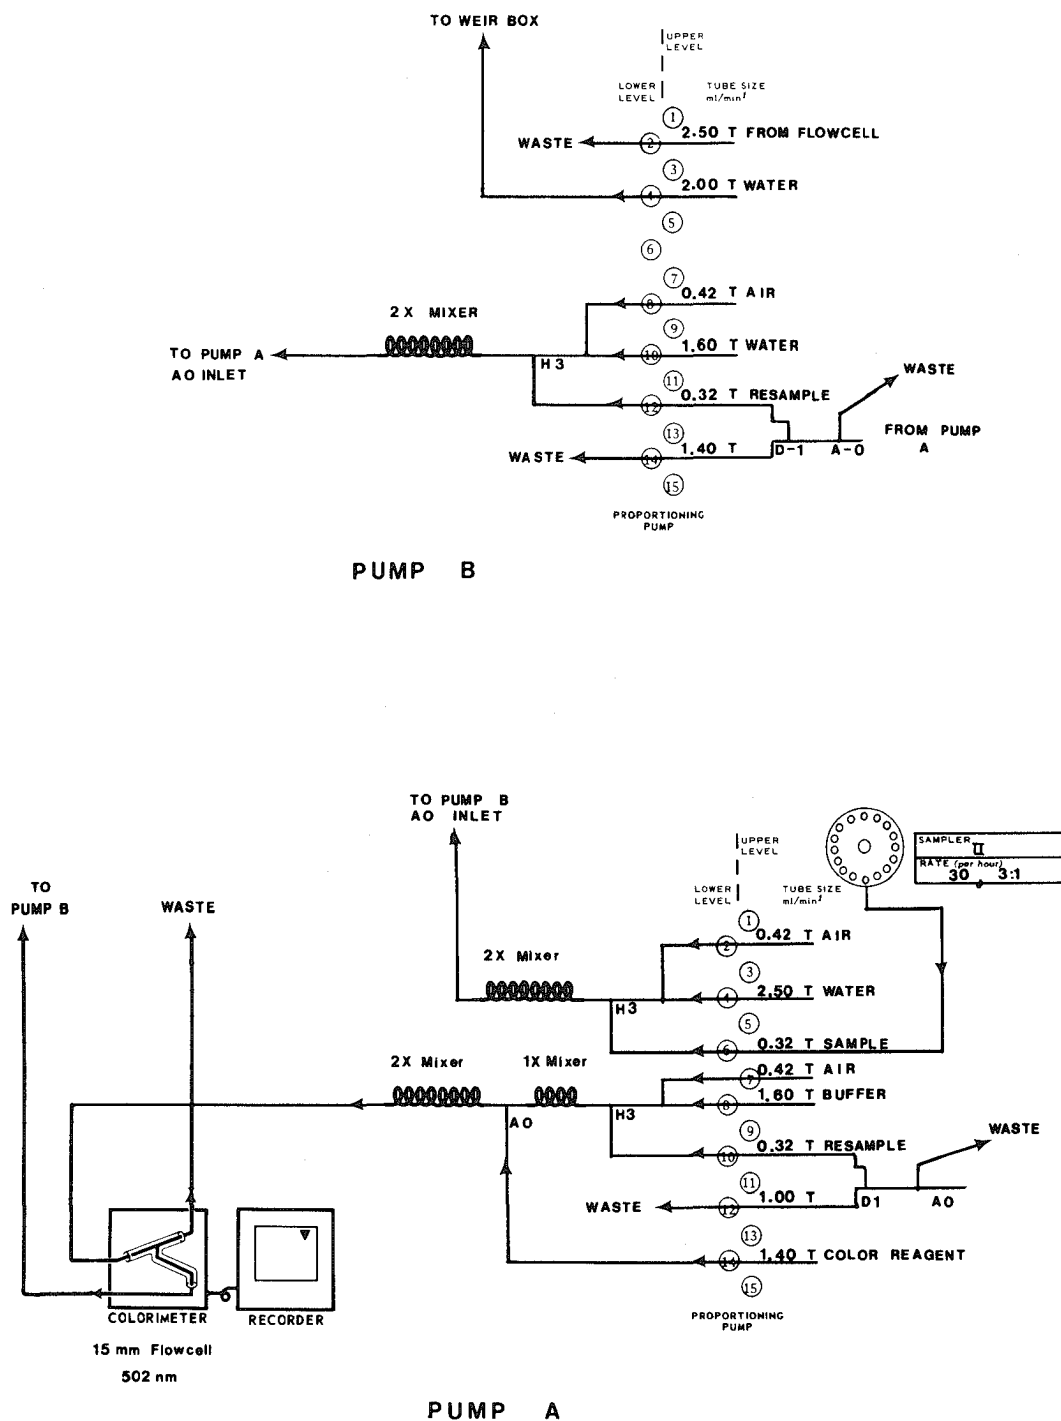

FIG. 36:02—Flow diagrams for semiautomated analysis for ferrous sulfate

baselines. Subtract baseline to det. net  $A$  and  $A'$  for each sample and std peak, resp. Discard values for first 2 and last std peaks and calc. av. std  $A'$ .

$$\text{mg Fe in portion taken} = (A/A') \times C \times D,$$

where  $C$  = concn of std in mg/mL and  $D$  = diln factor.

### Mercury (32)—Official Final Action

(Applicable to Hg in phenylmercuric chloride,  $\text{HgI}_2$ , nitromersol,  $\text{HgO}$  ointment, and calomel tablets. *Caution:* See 51.079.)

#### 36.079

#### Reagents

- (a) *Strychnine sulfate soln.*—Approx. 0.01*M*; 4.3 g/500 mL.  
 (b) *Valser's reagent.*—Dissolve 10 g KI in  $\text{H}_2\text{O}$  and dil. to 100 mL. Sat. with  $\text{HgI}_2$  (ca 14 g) and filter.

#### 36.080

#### Apparatus

- (a) *Digestion flask.*—Acetylation or r-b, 100 mL, fitted to  $\text{H}_2\text{O}$ -cooled straight-tube condenser with  $\text{F}$  joint.  
 (b) *Gooch crucibles.*—Fitted with 21 mm filter paper disks, covered with thin layer of asbestos (*Caution:* See 51.086), and dried at  $105^\circ$ . Use to filter and weigh ppt of strychnine.HI.HgI<sub>2</sub>.

#### 36.081

#### Preparation of Samples

(*Caution:* See 51.047.)

Accurately weigh (avoid use of metal containers) or measure sample contg 20–100 mg Hg (optimal ca 50 mg) and treat as follows:

- (a) *Solns of organic mercurials.*—Transfer sample to beaker and evap. just to dryness with low heat ( $60$ – $70^\circ$ ) and air current. Dissolve residue in ca 5 mL 10% NaOH soln and transfer to digestion flask. Rinse beaker with four 3–4 mL portions  $\text{H}_2\text{O}$  and add rinsings to digestion flask. Add excess liq. Br to soln and connect flask to condenser. Boil 4–5 min and add 3 mL HCl thru top of condenser. Continue to heat soln until Br collects in condenser tube. Remove heat and cool until Br returns to soln in digestion flask.

Alternately heat and cool until Br has almost completely dissipated. (After 3 intervals of heating, flow of  $\text{H}_2\text{O}$  thru condenser may be discontinued to aid in removing Br.) Let flask cool, and rinse inside of condenser with ca 5 mL  $\text{H}_2\text{O}$ . Disconnect flask and rinse tip of condenser with small stream of  $\text{H}_2\text{O}$  from wash bottle. Filter thru 9 cm paper into 150 mL beaker, and rinse flask and filter with four 5 mL portions  $\text{H}_2\text{O}$ .

- (b) *Ointments.*—Transfer sample to digestion flask and add 5 mL HCl (1+3) followed by 5 mL satd Br- $\text{H}_2\text{O}$ . Add small pieces of porcelain, SiC, or few glass beads to prevent bumping. Connect flask to condenser and fit flask over hole cut in asbestos board so that bottom extends just below undersurface of board. Heat over low flame, maintaining slow and continuous boiling ca 10 min, and then cool to room temp. Disconnect flask and decant aq. portion thru 9 cm paper into 150 mL beaker. Take precautions to retain all ointment base in flask. Rinse neck of flask into filter with few drops of  $\text{H}_2\text{O}$  from wash bottle. Add 1 mL HCl (1+3), 1 mL satd Br- $\text{H}_2\text{O}$ , and 8 mL  $\text{H}_2\text{O}$  to flask and reflux. Again cool contents of flask and decant aq. phase thru filter.

Repeat refluxing and decanting with two 10 mL portions  $\text{H}_2\text{O}$  and finally rinse condenser tube into flask with ca 5 mL  $\text{H}_2\text{O}$ . Disconnect flask, rinse condenser tip, and decant rinsings thru filter. Rinse filter with 2 small portions  $\text{H}_2\text{O}$  from wash bottle.

Test for complete removal of Hg by adding 5 mL  $\text{H}_2\text{O}$  and 2 drops HCl (1+3) to digestion flask and refluxing as before. Pass this soln thru original filter into 50 mL beaker. To filtrate add 1 drop 10% KI soln and 1 drop strychnine sulfate soln. No turbidity

should be produced. If extn is incomplete, repeat refluxings with  $\text{H}_2\text{O}$  until all Hg is removed. Reserve all test solns showing presence of Hg to add to major portion after pptn of Hg.

- (c) *Calomel tablets.*—Det. av. wt/tablet. Grind to fine powder and transfer accurately weighed portion to digestion flask. Add 10 mL satd Br- $\text{H}_2\text{O}$  and 5 mL HCl (1+3). Connect flask to reflux condenser and gently boil contents until most of Br vapors collect in condenser. Discontinue heating until Br returns to soln in flask. Repeat alternate heating and cooling until Br vapors are dissipated. Cool flask and contents to room temp. and rinse condenser tube with ca 10 mL  $\text{H}_2\text{O}$ . Disconnect flask and rinse condenser tip into flask. Filter soln thru gooch into 150 mL beaker. Rinse flask with three 5 mL portions  $\text{H}_2\text{O}$  and pass rinsings thru crucible, and finally rinse crucible with fine stream of  $\text{H}_2\text{O}$ .

- (d) *Tablets containing purgative drugs.*—If tablets contain purgative drugs, add 10 mL alcohol to weighed sample in flask. Heat on steam bath with gentle agitation until alcohol begins to boil. Remove flask, cool under tap, and filter supernate thru gooch fitted with asbestos mat. Retain as much of insol. residue in flask as possible. Rinse flask and contents with three 10 mL portions alcohol and two 5 mL portions  $\text{H}_2\text{O}$ , and decant thru crucible as above. Remove asbestos mat with fine wire or needle and transfer to flask. Rinse crucible with 10 mL satd Br- $\text{H}_2\text{O}$  and 5 mL HCl (1+3), and add rinsings to flask. Connect flask to condenser, and treat as in (c).

#### 36.082

#### Determination

Add 10 mL 10% KI soln to filtrate, and if necessary, evap. on steam bath under air current to ca 50 mL. If soln has not previously been acidified, add 3 mL HCl (1+3). Add 1%  $\text{NaHSO}_3$  soln until I color is discharged, and keep soln free from I color by addn of  $\text{NaHSO}_3$  soln until final filtration is made. Add strychnine sulfate soln slowly from buret or pipet until ppt coagulates and settles rapidly. (Strychnine sulfate soln may be added as rapidly as it will flow from buret if theoretical amt is used, based on 1 mL soln for each 4 mg Hg expected to be present.) Avoid undue excess of strychnine because of slight solubility of its hydriodide.

Let ppt settle and test for complete pptn by adding 2–3 drops strychnine sulfate soln to clear supernate. If pptn is incomplete, indicated by cloudiness around the drops, add strychnine sulfate soln in 1 mL increments until pptn is complete. Let ppt remain in beaker with occasional stirring 0.5–1 hr.

Decant supernate thru weighed gooch, 36.080(b). Wash ppt into crucible with fine stream of  $\text{H}_2\text{O}$ . Completely transfer ppt to crucible, and wash residue and crucible with three 5 mL portions  $\text{H}_2\text{O}$ . Scrub beaker thoroly with policeman. Transfer crucible and holder to another small suction flask and wash residue with 2–3 mL  $\text{H}_2\text{O}$ . Test filtrate for complete removal of strychnine by addn of Valser's reagent. If necessary, continue washing ppt with small portions  $\text{H}_2\text{O}$  until last washings give no more than faint opalescence upon addn of Valser's reagent. Always test main filtrate by addn of ca 1 mL strychnine sulfate soln to assure complete pptn of Hg. If pptn is incomplete, repeat detn. Dry crucible 1 hr at  $105^\circ$ , cool in desiccator, and weigh. Calc. % Hg compd in sample on basis of MW of 916.74 for ppt of strychnine.HI.HgI<sub>2</sub>.

### Merbromin (Mercurochrome®) (33)

#### 36.083 Tests for Purity—Procedure

- (a) Acidify portion of merbromin soln with 10%  $\text{H}_2\text{SO}_4$  and filter off ppt. Filtrate is only slightly yellow.  
 (b) Pass  $\text{H}_2\text{S}$  (*Caution:* See 51.059) into portion of filtrate. No ppt or coloring occurs.

(c) Add few mL 10%  $\text{HNO}_3$  to another portion of filtrate and add  $\text{AgNO}_3$  soln. No ppt forms.

### 36.084 Total Solids in Solution—Official Final Action

Pipet 10 mL merbromin soln into tared, extra-wide-form weighing bottle and evap. to dryness on steam bath. Let dry overnight in open bottle in desiccator contg  $\text{H}_2\text{SO}_4$ . Weigh.

### 36.085 Determination of Mercury—Official Final Action

(Caution: See 51.019, 51.030, 51.039, 51.040, 51.048, 51.049, 51.059, 51.080, and 51.086.)

Pipet 10 mL ca 2% merbromin soln into 500 mL tall beaker and evap. to dryness on steam bath (or accurately weigh ca 0.2 g powder). Dissolve residue in 4 mL  $\text{H}_2\text{O}$  and slowly add, with const mixing, 10 mL  $\text{H}_2\text{SO}_4$ . Incline beaker and cautiously add small portions finely powd  $\text{KMnO}_4$ , mixing after each addn, until deep purple color shows that considerable excess has been added. Let stand 30 min, mixing occasionally. Mixt. should still be purple.

Add 100 mL  $\text{H}_2\text{O}$  and mix thoroly. Add small portions finely powd oxalic acid, mixing after each addn, until soln is clear. Filter thru small filter into 400 mL beaker, wash original beaker and filter until filtrate measures ca 200 mL, and pass  $\text{H}_2\text{S}$  thru soln 20 min. Warm on steam bath until ppt of  $\text{HgS}$  settles quickly after stirring, and again pass  $\text{H}_2\text{S}$  thru warm soln 5 min. Immediately filter soln into weighed gooch; thoroly wash ppt on filter with  $\text{H}_2\text{O}$ , 3 times with alcohol, and then with 4 or 5 portions  $\text{CCl}_4$  or  $\text{CS}_2$ , letting liq. run thru crucible without suction; finally wash with ether. Dry ppt to const wt at  $100^\circ$  and weigh as  $\text{HgS}$ .  $\text{HgS} \times 0.8622 = \text{Hg}$ .

Qual. test dried ppt for Hg and other heavy metals. If slow filtration occurs during washing with  $\text{H}_2\text{O}$ , let ppt drain, and wash once with alcohol; then continue as directed.

### 36.086 Mercurous Chloride (Calomel) in Ointments (34) Official Final Action

Accurately weigh ca 1 g ointment, transfer to 250 mL g-s erlenmeyer, and treat with ca 50 mL  $\text{CHCl}_3$ . When base is dissolved, decant thru dry, closely packed asbestos mat in Caldwell crucible (Caution: See 51.086), using light suction. Wash flask and contents several times with 20–30 mL portions  $\text{CHCl}_3$ , decanting thru crucible. Let any residual  $\text{CHCl}_3$  in flask evap., and transfer asbestos mat and contents to flask, wiping sides of crucible and mouth of flask with damp piece of filter paper and adding it to flask. Add 2.5 g KI and 30 mL std 0.1N I, 50.018 (stdzd against  $\text{Na}_2\text{S}_2\text{O}_3$ ), stopper, and mix well. Let stand ca 1.5 hr or until soln of calomel is complete, agitating frequently and fairly vigorously. Titr. with 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , 50.038, adding 1 or 2 mL excess and using starch indicator, 6.005(f). When all traces of I disappear, back-titr. with std I soln to blue color. 1 mL 0.1N I = 0.02360 g  $\text{Hg}_2\text{Cl}_2$ .

### 36.087 Mercurous Chloride (Calomel) in Tablets (35) Official Final Action

Count and weigh representative number of tablets. Powder tablets and accurately weigh well mixed sample contg 0.19–0.26 g (3–4 grains)  $\text{Hg}_2\text{Cl}_2$ . Transfer to 200 mL g-s erlenmeyer, add ca 50 mL  $\text{H}_2\text{O}$ , acidify with  $\text{HOAc}$ , and after sol. fillers dissolve, decant with aid of suction thru tightly packed asbestos mat placed on plate of Caldwell crucible (Caution: see 51.086). Wash once with  $\text{H}_2\text{O}$  by decantation and then successively with alcohol and ether. Transfer removable plate holding mat and insol. material to original flask, washing into flask any insol. material adhering to sides of crucible. Add 2.5 g KI, 10 mL  $\text{H}_2\text{O}$ , and then 30 mL std 0.1N I soln, 50.018. Complete detn as in 36.086.

### 36.088 Mercurous Iodide in Tablets (36) Official Final Action

Accurately weigh well mixed powd sample contg 0.19–0.26 g (3–4 grains)  $\text{Hg}_2\text{I}_2$ . Transfer sample to 200 mL g-s flask, and proceed as in 36.087, omitting addn of  $\text{H}_2\text{O}$  after the KI. 1 mL 0.1N I = 0.03275 g  $\text{Hg}_2\text{I}_2$ .

Note: Some com. tablets are difficult to filter thru asbestos mat without loss of  $\text{Hg}_2\text{I}_2$ . Placing few drops of alumina cream, 31.021(b), on mat before filtration is started (wash free from  $\text{NH}_3$ ), satisfactorily prevents loss, tho it retards filtration.

### 36.089 Mercury in Mercurial Ointment (37) Official Final Action

(Caution: See 51.011 and 51.026.)

After mixing ointment thoroly with glass rod, avoiding contact with metals, weigh 1 g sample into erlenmeyer. Add 20 mL  $\text{H}_2\text{O}$  and 20 mL  $\text{HNO}_3$ , and heat gently over small flame until red fumes cease to evolve. Cool, and decant aq. soln from ointment base into separator. Wash ointment base with 50 mL boiling  $\text{H}_2\text{O}$ , cool, and decant into separator. Repeat washing until all Hg is removed.

Shake combined solns in separator with 50 mL ether. Transfer aq. soln to erlenmeyer. Wash ether soln with three 10 mL portions  $\text{H}_2\text{O}$  until Hg is removed, adding washings to flask. Add 3 mL  $\text{FeNH}_4(\text{SO}_4)_2$  soln, 36.036(b), and titr. with 0.1N  $\text{NH}_4\text{SCN}$ . 1 mL 0.1N  $\text{NH}_4\text{SCN}$  = 0.01003 g Hg.

### 36.090 ★ Mercury in Ointment of Mercuric Nitrate (38) ★ Official Final Action

(Caution: See 51.011 and 51.026.)

Transfer, to 200–300 mL erlenmeyer, 3–5 g sample, accurately weighed, using glass or bone spatula. Add 40 mL  $\text{HNO}_3$  (1+1) and few glass beads, and insert short-stem funnel into neck of flask. Boil gently 1–1.5 hr on hot plate or over low flame. (With latter, use piece of asbestos with circular hole under asbestos wire gauze.) Add 30 mL  $\text{H}_2\text{O}$ , using part to wash funnel. Cool enough (ca  $20^\circ$  or below) to cause solidification of unconsumed fat. Filter thru 11 cm paper into 200 mL vol. flask. Wash fat, flask, and filter, using ca 100 mL 1%  $\text{HNO}_3$ . Dil. to vol. and mix well. Reserve fat to test for complete extn as below.

Test for complete extn of Hg from fat and its removal from filter, etc., by repeating  $\text{HNO}_3$  digestion ca 30 min on residual fat in flask or on filter, completing this as sep. detn, including  $\text{KMnO}_4$  digestion. Add any titrn in excess of 1–2 drops (0.05–0.08 mL 0.1N  $\text{NH}_4\text{SCN}$ ) resulting from this test portion to that obtained by titrg main ext.

Transfer 100 mL aliquot to 500 mL erlenmeyer. Add 7 mL  $\text{HNO}_3$ , 5 mL  $\text{H}_2\text{SO}_4$ , and 2 g powd  $\text{KMnO}_4$ , and rotate to dissolve. Heat just to bp over low flame or on hot plate. Boil gently 45 min, maintaining excess of  $\text{KMnO}_4$ , indicated by dark purple color. (Excess is essential.) When adding  $\text{KMnO}_4$  to boiling liq., use smaller portions (ca 0.5 g or less) to avoid loss due to frothing.

Caution: Use of greater excess of  $\text{KMnO}_4$  than necessary is not objectionable, but proportionately more  $\text{H}_2\text{O}_2$  is required to remove it and  $\text{MnO}_2$  at end of digestion. Usually ca 10 g is required. Rate of consumption and total  $\text{KMnO}_4$  consumed appear to vary with temp., org. matter present, and period of heating. Large amt of  $\text{MnO}_2$  formed may lead to wrong conclusion concerning color indicative of excess of  $\text{KMnO}_4$ . Frequent examination of soln is necessary. Observation of this color is aided by looking thru supernate toward white background while inclining container.

★ Surplus method—see inside front cover.

Remove excess  $\text{KMnO}_4$  and dissolve  $\text{MnO}_2$  by adding  $\text{H}_2\text{O}_2$  (5–10%, prepd from 30%) dropwise to hot soln. When colorless, add 2%  $\text{KMnO}_4$  soln slowly until faint pink or brown persists ca 1 min. If large amt of  $\text{MnO}_2$  forms at this point, again use  $\text{H}_2\text{O}_2$  sparingly; then use  $\text{KMnO}_4$  to discharge the  $\text{H}_2\text{O}_2$ . Discharge color from last addn of  $\text{KMnO}_4$ , including weak brown from  $\text{MnO}_2$ , by adding dropwise just enough 8%  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$  soln. Cool to ca  $20^\circ$ , add 3 mL ca 0.5*N*  $\text{FeNH}_4(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ , and titr. with std 0.1*N*  $\text{NH}_4\text{SCN}$ . 1 mL 0.1*N*  $\text{NH}_4\text{SCN}$  = 0.01003 g Hg.

#### Nitrites in Tablets—Official Final Action

##### 36.091 ★ Hydrazine Method (39) ★

(Applicable in presence or absence of nitrates or chlorides)

Nitrites react with excess std hydrazine sulfate and excess is titrd with std I soln. See 36.080–36.081, 12th ed.

#### Silver Proteinates (40)—Official Final Action

##### 36.092 Total Silver

(Caution: See 51.011 and 51.026.)

Place 1 g sample, accurately weighed, in 500 mL Kjeldahl flask; add 15 mL  $\text{H}_2\text{SO}_4$  and then 10 mL  $\text{HNO}_3$ . Place on steam bath few min, with occasional rotation, to ensure homogeneous mixt., and boil to white fumes. Add more  $\text{HNO}_3$ , boil again to clear colorless soln, and cool. Add 100 mL  $\text{H}_2\text{O}$  and boil until free of N oxides. Cool, dil. to 300 mL, add 5 mL  $\text{HNO}_3$  and 5 mL  $\text{FeNH}_4(\text{SO}_4)_2$  soln, 36.030(b), and titr. with 0.1*N*  $\text{NH}_4\text{SCN}$ . 1 mL 0.1*N*  $\text{NH}_4\text{SCN}$  = 0.01079 g Ag.

##### 36.093 Ionizable Silver Compounds

Weigh strip of com. dialyzing tubing 55 mm wide and ca 30 cm long, wet with  $\text{H}_2\text{O}$  until uniformly pliable, shake free of adhering  $\text{H}_2\text{O}$ , and partially dry by rolling in clean paper towel. Reweigh while still moist and place in 250 mL beaker. (Sheets of dialyzing parchment paper may be used in place of tubing. Over one end of glass tube 10 cm long and ca 2.5 cm od, fold and secure with rubber band sq piece of parchment paper in form of sack large enough to hold sample soln. Dialyzing material should be kept in humid container to prevent breaking when handled.)

Weigh 1 g sample, dissolve in 15 mL  $\text{H}_2\text{O}$ , and transfer to dialyzing tube. Calc., and add enough  $\text{H}_2\text{O}$  to beaker to make 100 mL (this ensures 20 mL in dialyzing tube and 80 mL in beaker). Adjust tubing to form "U" in beaker, cover with watch glass, and keep cool and in dark 24 hr.

(a) *Qualitative test*.—Test few mL clear, colorless soln from beaker for Ag ions by addn of few drops HCl (1+3) and trace of  $\text{HNO}_3$ .

(b) *Determination*.—If Ag ions are present, remove 50 mL clear, colorless soln (representing 0.5 g sample) from beaker, dil. to 100 mL, and add 2 mL  $\text{FeNH}_4(\text{SO}_4)_2$  soln, 36.030(b), and 2 mL colorless  $\text{HNO}_3$ . Titr. with 0.01*N*  $\text{NH}_4\text{SCN}$  and calc. to % by wt ionizable Ag. 1 mL 0.01*N*  $\text{NH}_4\text{SCN}$  = 0.001079 g Ag.

#### MYDIATICS AND MYOTICS

##### 36.094 ★ Cat-Eye Bioassay Method (41) ★ Official Final Action

Contraction of pupil of cat eye treated with sample is compared to that of eye treated with control std prepn, with untreated eye as control, all exposed to 100 watt elec. lamp at 1' distance. See 36.084–36.088, 12th ed.

★ Surplus method—see inside front cover.

#### MICROSCOPIC TESTS

##### Microchemical Tests

##### For Alkaloids and Related Amines—Official Final Action

##### 36.095

##### Reagents

(a) *Ammoniacal silver nitrate soln*.—Mix 2.5 mL 4%  $\text{AgNO}_3$  soln with 2.5 mL  $\text{NH}_4\text{OH}$  (1+5). Prep. fresh.

(b) *Ammonium hydroxide soln*.—10%  $\text{NH}_3$  (2+3).

(c) *Ammonium thiocyanate soln*.—Dissolve 5 g  $\text{NH}_4\text{SCN}$  in 100 mL  $\text{H}_2\text{O}$ .

(d) *Bismuth iodide soln*.—(1) Prep. stock concd  $\text{Bi}(\text{NO}_3)_3$  soln by dissolving 50 g Bi subnitrate in 70 mL  $\text{HNO}_3$  (1+1) and dilg to 100 mL with  $\text{H}_2\text{O}$ . (2) Dissolve 1.25 g KI in 4.5 mL  $\text{H}_2\text{O}$  and add 0.5 mL stock concd  $\text{Bi}(\text{NO}_3)_3$  soln. Prep. fresh when soln darkens appreciably.

(e) *Bismuth iodide in diluted sulfuric acid soln*.—Dissolve 1.25 g KI in 2.0 mL  $\text{H}_2\text{O}$ , and add 2.5 mL  $\text{H}_2\text{SO}_4$  (1+3) and 0.5 mL stock concd  $\text{Bi}(\text{NO}_3)_3$  soln, (d)(1). Prep. fresh daily.

(f) *Sodium phosphate soln*.—Dissolve 5 g  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

(g) *Gold bromide in hydrochloric acid soln*.—Dissolve 1 g  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  and 1.5 mL 40% HBr in 18 mL HCl. (Satd aq. NaBr soln may be substituted for the HBr.)

(h) *Gold chloride soln*.—Dissolve 1 g  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  in 20 mL  $\text{H}_2\text{O}$ .

(i) *Hydrochloric acid*.—5% (1+6).

(j) *Iodine-potassium iodide soln*.—Dissolve 1.27 g I and 2 g KI in 5 mL  $\text{H}_2\text{O}$ , and dil. to 100 mL.

(k) *Lead iodide soln*.—To aq. KOAc soln (1+3) add 1 drop Me red and HOAc until yellow changes to orange; then, while gently warming, sat. with  $\text{PbI}_2$ , cool, and filter.

(l) *Mercuric chloride soln*.—Dissolve 5 g  $\text{HgCl}_2$  in 100 mL  $\text{H}_2\text{O}$ .

(m) *Mercuric chloride-sodium chloride soln*.—Dissolve 5 g  $\text{HgCl}_2$  and 0.75 g NaCl in 100 mL  $\text{H}_2\text{O}$ .

(n) *Platinic chloride soln*.—Dissolve 5 g  $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

(o) *Potassium cadmium iodide soln*.—Dissolve 3 g  $\text{CdI}_2$  in 18 mL  $\text{H}_2\text{O}$  contg 6 g KI.

(p) *Potassium ferrocyanide soln*.—Dissolve 5 g  $\text{K}_4\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

(q) *Potassium hydroxide soln*.—Dissolve 5 g KOH in 100 mL  $\text{H}_2\text{O}$ .

(r) *Potassium iodide soln*.—Dissolve 5 g KI in 100 mL  $\text{H}_2\text{O}$ .

(s) *Potassium permanganate soln*.—Dissolve 1 g  $\text{KMnO}_4$  in 100 mL  $\text{H}_2\text{O}$ .

(t) *Reinecke salt soln*.—Dissolve 0.1 g  $\text{NH}_4[\text{Cr}(\text{NH}_3)_2(\text{SCN})_4] \cdot \text{H}_2\text{O}$  and 0.03 g  $\text{H}_2\text{NOH} \cdot \text{HCl}$  in 10 mL alcohol. Filter, and store in refrigerator. (Reagent is stable  $\geq 6$  months.)

(u) *Sodium benzoate soln*.—Dissolve 5 g Na benzoate in 100 mL  $\text{H}_2\text{O}$ .

(v) *Sodium carbonate soln*.—Dissolve 5 g  $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$  in 100 mL  $\text{H}_2\text{O}$ .

(w) *Sodium iodide soln*.—Dissolve 5 g NaI in 100 mL  $\text{H}_2\text{O}$ .

(x) *Sodium nitroprusside*.— $\text{Na}_2\text{Fe}(\text{CN})_5\text{NO} \cdot 2\text{H}_2\text{O}$  crystals.

(y) *Zinc chloride soln*.—Dissolve 5 g  $\text{ZnCl}_2$  in 100 mL  $\text{H}_2\text{O}$ .

(z) *Zinc potassium iodide soln*.—Dissolve 5 g  $\text{Zn}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  and 20 g KI in 100 mL  $\text{H}_2\text{O}$ .

##### 36.096

##### Preparation of Samples

(a) *Usual controls*.—Dissolve 0.4 or 0.2 mg pure alkaloid salt in 0.04 mL  $\text{H}_2\text{O}$  to make ca 1:100 or 1:200 soln.

(b) *Alkaloids in compounds*.—Sep. alkaloid in pure form by extg it from ammoniacal soln with suitable immiscible solv., and evap. solv. Dissolve little of residue in min. of 0.1*N* HCl and

dil. with H<sub>2</sub>O, if necessary, to ca alkaloid concn specified in (a) or in test.

(c) *Hypodermic tablets*.—Dissolve portion of tablet in drop of H<sub>2</sub>O to ca same alkaloid concn specified in (a) or in test.

**36.097****Identification**

Place drop (ca 0.04 mL) of alkaloid soln on glass slide, add drop of reagent, and without stirring or covering, examine under microscope, using magnification of ca 100–500×. Note kind of crystals formed. Compare their characteristics with descriptions given, Table 36:03, and with a control. Use polarizing microscope if available, and note characteristics such as birefringence and dichroism.

**For Barbiturates (62)—Official Final Action****36.098****Reagent**

*Iodine-potassium iodide soln*.—Dissolve 5 g I and 80 g KI in enough H<sub>2</sub>O (ca 78 mL) to make 100 mL. Dil. with 2 parts by vol. of H<sub>3</sub>PO<sub>4</sub>. Prep. dild reagent every 2–3 weeks.

**36.099****Identification**

Dissolve little barbiturate in drop H<sub>2</sub>O on slide. If present as Na salt, it dissolves readily; if present as acid, add little droplet 1% NaOH on stirring rod and mix. Add 1 full drop reagent and let stand until crystn occurs (immediate with some compds, 0.5–1 hr with secobarbital). Free acid may ppt or crystallize.

**Table 36:03 Characteristics of Microchemical Tests for Alkaloids and Related Amines**

Alkaloid	Reagent	Description of Crystals
Aconitine (42)	Sodium carbonate	In 1:3000 soln heated to 50° in test tube. Small, transparent, hexagonal plates; also rods in contact.
Amylocaine (43)	1 drop HCl and 1 drop gold chloride	1:50. Dendritic crystals.
Apomorphine (44)	Potassium iodide Gold chloride Hydrochloric acid	1:50. Small crystals that have sharp, clear-cut angles like those of diamond. Red-brown, fine needles, in dense masses in all solns to 1:10,000. 1:50. Small rods singly and in clusters.
Arecoline (42)	Bismuth iodide	Red, rhombic crystals.
Atropine (45)	Iodine potassium iodide	Small, dark rods and triangular plates form in great numbers, singly and in groups.
Benzylmorphine (46) (Peronine)	Potassium iodide Ammonium thiocyanate Hydrochloric acid	1:200. Dense rosettes of needles. Crystals are formed readily in dil. solns (1:1000) in form of sheaves of needles. 1:200. Rosettes and sheaves of needles in acid or neut. soln. 1:100. Rods, usually notched at ends and often in rosettes, are formed on stirring.
Berberine (47)	Hydrochloric acid	Satd soln; fine yellow needles. (Avoid excess reagent.)
Brucine (48)	Potassium iodide Mercuric chloride	Long masses of transparent, rectangular plates; also rosettes of thin plates. Small, dense rosettes.
Choline (49)	Reinecke salt  Platinic chloride and sodium iodide	Add 1 drop acetone to 1 drop H <sub>2</sub> O soln of base. Stir, add 1 drop reagent, and stir again. 1:100. Thin, hexagonal plates and star-shaped forms. 1:1000–1:10,000. Six-sided, more coffin-shaped plates; sometimes rosette aggregates of plates on edge, resembling needles. 1:100 in H <sub>2</sub> O. Add 1 drop H <sub>2</sub> PtCl <sub>6</sub> soln, stir, and add small drop NaI soln without stirring. Small black rectangular prisms and slender black rods.
Cinchonidine (50)	Sodium benzoate Platinic chloride Sodium carbonate	Rosettes and sheaves of needles spreading to large size. Rosettes of transparent plates. Spherical crystals, but not needles as in cinchonine.
Cinchonine (50)	Sodium carbonate Disodium phosphate	Dark rosettes, composed of radiating needles, form immediately. Similar to crystals formed by Na <sub>2</sub> CO <sub>3</sub> , but more burr-shaped.
Cocaine (51)	Platinic chloride	Delicate, feathery crystals, later becoming heavier in structure.
Codeine (51)	Potassium cadmium iodide Iodine potassium iodide	Silvery, circular masses, crystg into dark rosettes of irregular outline. Heavy, red-brown ppt; crystallizes very slowly in yellow blades extending in branches (never red).
Cotarnine (47)	Platinic chloride Mercuric chloride Potassium ferrocyanide	1:200. Hair-like crystals, yellow and curving. Colorless, long, branching needles. Acidify with 1 drop 5% HCl; globules that develop into dense, burr-shaped crystals; also amber-brown plates.
Dihydromorphinone (52)	Sodium nitroprusside	To minute amt (<1 mg) in 2 drops H <sub>2</sub> O add minute fragment of reagent. Elongated 6-sided prisms; also in aggregates.
Ephedrine (53)	Bismuth iodide in dild sulfuric acid	1:200. Long, brownish orange, radiating and interlacing needles and branching rods.
Ethylhydrocupreine (54)	Ammonium thiocyanate	1:100 in 0.1N HCl. Long, straight needles.
Ethylmorphine (46)	Iodine potassium iodide Mercuric chloride	1:200. Groups of yellow needles, branching later. Transparent plates, often with notched ends; singly and in groups. Stir to start crystn.
Heroin (55) (Diacetyl-morphine)	Platinic chloride	Spherical clusters of golden yellow needles form slowly around nucleus; cluster disintegrates on standing.
Homatropine (56)	Gold chloride	1:200. Green-gold blades, often with pointed ends and united in pairs; surfaces appear etched on long standing.
Hydrastine (44)	1 drop 5% HCl and 1 drop potassium ferrocyanide	1:100. Spheres of radiating crystals. Shake slide to start crystn. Avoid excess reagent.

(Continued)

**Table 36:03 Characteristics of Microchemical Tests for Alkaloids and Related Amines—Continued**

Alkaloid	Reagent	Description of Crystals
Hydrastinine (46)	Potassium permanganate	1:500. Immediate red plates, often with serrated edges. In concd soln, great number of large red or brown plates with deeply cut edges.
	Mercuric chloride 1 drop 5% HCl and 1 drop potassium ferrocyanide	1:500. Transparent needles forming branches rapidly in neut. and acidified solns. 1:200. Yellow rhombic plates and tree-like crystals.
Hyoscyamine (56)	Gold chloride	Thin, transparent, nearly colorless irregular plates, often curved. Crystals form slowly in 1:100 to 1:200 soln. Shaking slide aids crystn.
Morphine (51)	Potassium cadmium iodide Iodine potassium iodide	Silvery, gelatinous ppt, crystg in dense masses of fine needles. Small drop of reagent produces heavy, red-brown ppt, slowly crystg in shining, red, overlapping plates extending in branches.
Narceine (47)	Iodine potassium iodide or zinc potassium iodide	1:400. Blue, radiating needles, sometimes with yellow dichroism.
	Platinic chloride	Beautiful feathery rosettes develop in all solns.
Nicotine (57)	Mercuric chloride	Radiating, transparent blades form in presence of slight excess of H <sub>2</sub> SO <sub>4</sub> ; feather-like blades form in presence of HCl.
	Mercuric chloride-sodium chloride	Radiating, transparent blades.
Noscapine (47) (l-Narcotine)	Potassium hydroxide or ammonium hydroxide	1:200. White, amorphous ppt that crystallizes slowly; dense rosettes of needles.
Papaverine (58)	Zinc chloride	Thin, rectangular plates in excess HCl.
Physostigmine (59)	Lead iodide	1:100. Radiating, serrated plates.
	Gold bromide in HCl	1 mg in 1 drop H <sub>2</sub> O. Brown, dendritic aggregates.
Pilocarpine (45)	Platinic chloride	Crystals form slowly; layers of thin, yellow, triangular plates of delicate structure.
Procaine (58)	Platinic chloride	Spherical crystals of radiating branches.
	Gold chloride and HCl	Irregular, radiating branches.
Quinidine (50)	Potassium iodide	Small, triangular crystals in great numbers; best in 1:1000 diln; sol. in excess reagent.
Quinine (50)	Disodium phosphate	Silvery, sheaf-like crystals.
Racephedrine (60) (dl-Ephedrine)	Bismuth iodide in dild sulfuric acid	1:200. Large orange plates and red prisms and grains.
Scopolamine (56) (Hyoscine)	Gold chloride	Clusters of pale yellow, transparent blades, with coarse, saw-toothed edges form immediately on shaking slide. Crystals grow to large size in 1:200 soln.
Sparteine (57)	Gold chloride	Large numbers of blade-like crystals varying in size according to concn.
Strychnine (61)	Platinic chloride	Crystals form immediately in clusters and singly in small, wedge-shaped needles that move about field.
	Potassium cadmium iodide	Silvery masses, slowly forming rosettes.
Yohimbine (42)	Sodium carbonate	In 1:1000 soln heated to 50°. Fine needles in sheaf-like bundles and rosettes.

However, l reaction crystals are easily distinguished by their color, often coupled with strong dichroism. Det. birefringence with polarizing microscope. Cover glass is usually not needed but may be used for observation at high magnification and when slide stands >1 hr; on standing, KI may crystallize as sq, colorless, isotropic crystals.

Note crystals formed and compare characteristics with descriptions, Tables 36:04 and 36:06.

#### **For Sympathomimetics (60)—Official Final Action**

##### **36.100**

##### **Reagents**

(a) *Bismuth iodide in diluted sulfuric acid soln.*— See 36.095(e).

(b) *Gold chloride in diluted phosphoric acid soln.*— Dissolve 1 g H<sub>2</sub>AuCl<sub>4</sub>·3H<sub>2</sub>O in 20 mL H<sub>3</sub>PO<sub>4</sub> (1+2).

(c) *Platinic chloride in diluted phosphoric acid soln.*—Dissolve 1 g H<sub>2</sub>PtCl<sub>6</sub>·6H<sub>2</sub>O in 20 mL H<sub>3</sub>PO<sub>4</sub> (1+3).

(d) *Sodium tetraphenylboron soln.*—Aq. soln (1+20).

##### **36.101**

##### **Identification**

(a) *Direct test.*—Add drop of reagent to little of powd solid or crushed tablet and spread out on slide with little stirring. Do not stir to homogeneity as local concns and dilns will assist crystn. Let stand to evap. to higher acid concn if necessary for crystal formation.

(b) *Volatility test.*—Place small amt of substance or crushed tablet in depression of cavity slide, add drop 5% NaOH soln, and stir briefly. Place very small drop of reagent on thin slide, invert over cavity slide, and let stand. As crystals appear, examine with inverted slide in place. After observing crystals or after ≥1 hr exposure, if only few or no crystals form, reinvert thin slide with hanging drop, and let stand for gradual evapn of H<sub>2</sub>O from reagent drop. Examine for crystals. Compare with descriptions, Table 36:05.

#### **For Synthetics—Official Final Action**

(See Table 36:06.)

**Table 36:04 Characteristics of Microchemical Tests for Barbiturates**

Barbiturate	Crystal Form	Dichroism or Pleochroism	Remarks
Allylbarbital (5-Allyl-5-isobutylbarbituric acid) "Itobarbital"	Immediate crystn in rods, splinters, and leaflike crystals with pointed ends.	Red to black dichroism.	Free acid may crystallize out.
5-Allyl-5-(2-cyclopenten-1-yl) barbituric acid	Gradual crystn in dichroic straight-edged blades, brown-yellow to brown-orange.	—	Very bright birefringence; free acid as colorless rods, splinters, needles.
Amobarbital (5-Ethyl-5-isoamylbarbituric acid)	Dil. soln: fairly large brown blades. Concd soln: multitudes of little pale-colored flakes.	—	Examine at 200×; sensitive test.
Aprobarbital (5-Allyl-5-isopropylbarbituric acid)	Light orange-brown rod-blades, birefringent.	Yellow to brown-orange dichroism.	—
Barbital (5,5-Diethylbarbituric acid)	Form very soon; fairly large, rectangular or splinter blades.	Extreme pleochroism by transmitted polarized light.	Beetle-green iridescence by reflected light.
* Bemegride (4-Ethyl-4-methyl-2,6-piperidinedione)	Small light-colored dichroic rods or blades and flakes or plates, orangish brown to colorless or yellowish.	—	Birefringence is bright and plates that are sq or nearly so extinguish diagonally.
Butabarbital Sodium (Sodium 5-sec-butyl-5-ethylbarbiturate)	Dil. soln: red-brown irregular plates. Concd soln: brown blades in clusters.	Slightly dichroic; dichroism yellow to red-brown.	Free acid: colorless blades.
Butethal (5-Butyl-5-ethylbarbituric acid)	Small plate crystals basically rhomboids. "Propeller-type" of elongate pointed blades.	Strong dichroism, light yellow to black.	—
Cyclobarbital (5-(1-Cyclohexenyl)-5-ethylbarbituric acid)	Dil. soln: rosettes of little pointed crystals; larger are red-brown plates.	Red-brown plates of variable dichroism frequently four-bladed.	Sensitive test.
Diallyl barbituric acid (5,5-Diallylbarbituric acid)	Crystallizes quickly in branching twigs, splinters, and blades.	Extreme black to "white" dichroism by polarized light.	Golden-beetle iridescence by reflected light.
Heptabarbital (5-(1-Cyclohepten-1-yl)-5-ethylbarbituric acid)	Little red-brown plates in great numbers, often 4-parted; good birefringence.	—	Sensitive.
Hexobarbital Sodium (Sodium 5-(1-cyclohexen-1-yl)-1,5-dimethylbarbiturate)	Dichroic blades and broad splinters in groups, varying to curving threads and needles in rosettes.	Very strong dichroism; black to light brownish yellow.	Sensitive for I reaction crystals as well as for free acid.
Metharbital (5,5-Diethyl-1-methylbarbituric acid)	Dark needles, small to large, and splintery narrow blades.	Dichroism black to brown.	Good birefringence with crossed nicols.
5-Methyl-5-phenylbarbituric acid	Red-brown irregular platy forms appear after free acid is pptd.	Gradually strongly dichroic rods or blades.	Test fairly sensitive for dil. soln.
Phenobarbital (5-Ethyl-5-phenylbarbituric acid)	Soon crystallizes in little dark grains; also a few larger red blades and dark splinter-rods in clusters.	—	Free acid may also crystallize out.
Probarbital (5-Ethyl-5-isopropylbarbituric acid)	Scattered iodine-reaction crystals form in various jagged shapes, color dark brown to black dichroism, or red-black with but little dichroism.	—	Free acid thrown out, forming long rods with pointed ends.
Secobarbital (5-Allyl-5-(1-methylbutyl)barbituric acid)	Crystallizes in plates or elongate and rectangular but mostly distorted into any shape after 1 hr.	Light yellow to orange or red dichroism by polarized light.	Distinctly birefringent.
Sodium Pentobarbital (Sodium 5-ethyl-5-(1-methylbutyl) barbiturate)	Crystallizes quickly in great numbers of small red-brown plates.	Minute light-colored flakes exhibit dichroism; dark brown or black to yellow.	—
Talbutal (5-Allyl-5-sec-butylbarbituric acid)	Amorphous ppt crystallizes in large needles and dichroic blades, lighter to deeper brown, in dendrites; then gray-black curled sheaves of threads.	—	Excellent test. Both types of crystals have good birefringence
Vinbarbital (5-Ethyl-5-(1-methyl-1-butenyl) barbituric acid)	Multitudes of small dark crystals, tiny grains and rods with dichroism brown to black. In quite dil. soln possible to get good small crystals, little dark rods with dichroism red to black, and small plates tending to be sq, generally appearing red but with same red to black dichroism, and with sq extinction (not diagonal).	—	Very sensitive.

\* This drug has barbiturate-type formula (although there is only one N) but is central nervous stimulant instead of depressant.

## 36.102

## Reagents

- (a) *Acetic acid*.—Dil. 6 mL HOAc to 100 mL with H<sub>2</sub>O.  
 (b) *Ammoniacal nickel acetate soln.*—Mix 1 vol. 5% Ni(OAc)<sub>2</sub>·4H<sub>2</sub>O soln with 1 vol. NH<sub>4</sub>OH (2+3). Use clear supernate.  
 (c) *Ammoniacal silver nitrate soln.*—See 36.095(a).  
 (d) *Ammonium thiocyanate soln.*—See 36.095(c).  
 (e) *Barium hydroxide soln.*—Satd aq. soln.  
 (f) *Benzaldehyde*.—USP quality.  
 (g) *Bismuth iodide soln.*—See 36.095(d).  
 (h) *Bromide-bromate soln.*—Dissolve 0.3 g KBrO<sub>3</sub> and 1.2 g KBr in H<sub>2</sub>O, and dil. to 100 mL.  
 (i) *Glycerol-alcohol mixture*.—(1+1).  
 (j) *Gold bromide in hydrochloric acid soln.*—See 36.095(g).

- (k) *Gold chloride soln.*—See 36.095(h).  
 (l) *Iodine-potassium iodide soln.*—See 36.095(j).  
 (m) *Lead acetate soln.*—Dissolve 5 g Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O in H<sub>2</sub>O and dil. to 100 mL.  
 (n) *Lead triethanolamine soln.*—Add 1 mL triethanolamine (tech. 90% is satisfactory) to soln of 1 g Pb(OAc)<sub>2</sub>·3H<sub>2</sub>O in 20 mL H<sub>2</sub>O. Slight turbidity does not interfere.  
 (o) *Magnesia mixture*.—Dissolve 5.5 g MgCl<sub>2</sub>·6H<sub>2</sub>O and 14.0 g NH<sub>4</sub>Cl in H<sub>2</sub>O. Add 13.05 mL NH<sub>4</sub>OH and dil. to 100 mL with H<sub>2</sub>O.  
 (p) *Mercuric chloride soln.*—See 36.095(l).  
 (q) *Mercurous nitrate soln.*—Dissolve 15 g HgNO<sub>3</sub>·H<sub>2</sub>O in mixt. of 90 mL H<sub>2</sub>O and 10 mL HNO<sub>3</sub> (1+9). Store in dark, amber bottle contg small globule of Hg.  
 (r) *Nitric acid*.—(1+1).

Table 36:05 Characteristics of Microchemical Tests for Sympathomimetics

Sympathomimetic	Reagent	Test	Description of Crystals
Volatile Substances			
<i>dl</i> -Amphetamine	Gold chloride in dild phosphoric acid	direct or volatility	Very irregular plates, with irregular blade-arms especially after evapn; sq if perfect.
	Platinic chloride in dild phosphoric acid	volatility	Irregular blades and needles, very low birefringence; after evapn, characteristic plates with narrow irregular arms of blades.
<i>d</i> -Amphetamine	Gold chloride in dild phosphoric acid	direct or volatility	Long yellow rods and blades; with evapn, some crystals as with <i>dl</i> may form.
	Platinic chloride in dild phosphoric acid	volatility	Long needles, often bent, very little birefringence; after some evapn, long rectangular blades. ( <i>l</i> -Ephedrine in direct test gives similar crystals which are more sol.; it is less volatile and does not normally form crystals in hanging drop.)
Epinephrine	Sodium tetraphenylboron	volatility	MeNH <sub>2</sub> liberated; birefringent X's or 4-arm crystals; also thick blades with central rib, pointed ends, pos. elongation.
Isoproterenol	Sodium tetraphenylboron	volatility	Isopropylamine liberated; plates tending to nonregular hexagons; no birefringence where plates lie flat but there are rods which are birefringent.
Methamphetamine and <i>dl</i> -Methamphetamine ( <i>d</i> - and <i>dl</i> -Desoxyephedrine)	Gold chloride in dild phosphoric acid	direct or volatility	Long blades and jointed crystals, fairly high birefringence.
	Platinic chloride in dild phosphoric acid	volatility	Grains with sharp edges which aggregate in chains and short prisms. Birefringent.
<i>dl</i> -Methamphetamine ( <i>dl</i> -Desoxyephedrine)	Bismuth iodide in dild sulfuric acid	volatility	Drops, crystg in orange-red prisms with conspicuously slanting ends; inclined extinction ca 20°; also "mossy" formation of grains and some large deep red grains.
	Freshly prepd gold chloride in dild phosphoric acid	volatility	Right-angled crossed blades with serrated and/or lobed edges.
	Aged (≥4 months) gold chloride in dild phosphoric acid	volatility	X blade formation with highly birefringent ribs visible in thin crystals or thickened X blades. Right-angled crossed blades are not present.
Methamphetamine ( <i>d</i> -Desoxyephedrine)	Bismuth iodide in dild sulfuric acid	volatility	Drops, long orange splinters, blades, needles; also deep red angular grains (red prisms only after evapn).
	Freshly prepd gold chloride in dild phosphoric acid	volatility	Numerous multiple "V"-shaped blades, few single "V"-shaped blades.
	Aged (≥4 months) gold chloride in dild phosphoric acid	volatility	Numerous single "V"-shaped blades.
Slightly Volatile Substances			
<i>dl</i> -Ephedrine (racephedrine)	Gold chloride in dild phosphoric acid	direct or volatility	Irregular plates based on the sq. growing along diagonals in 4 arms; some birefringent, some not.
	Bismuth iodide in dild sulfuric acid	volatility	Orange rods or sticks, short and stubby, some plates; more irregular plates on evapn.
<i>l</i> -Ephedrine	Gold chloride in dild phosphoric acid	direct or volatility	Long needles or splinters and long jointed forms; strong birefringence.
	Bismuth iodide in dild sulfuric acid	volatility	Long brownish orange needles, often branching or in sheaves; also, especially with evapn, orange irregular blades.
Pseudoephedrine	Gold chloride in dild phosphoric acid	direct or volatility (2 hr)	Thin branching sticks, many like combs; some broaden to blades or spear-head plates; very high birefringence.

(Continued)

**Table 36:05 Characteristics of Microchemical Tests for Sympathomimetics—Continued**

Sympathomimetic	Reagent	Test	Description of Crystals
Phenylpropanolamine	Gold chloride in dild phosphoric acid	direct	Plates and blades of extremely high birefringence, elongate hexagonal or diamonds, very bright colors. Branch into 4 or 6 irregular arms.
		volatility (2 hr)	After definite drying, pyramidal grains to blades and plates with irregular arms, very birefringent.
Phenmetrazine	Gold chloride in dild phosphoric acid	direct or volatility	Rectangular plates joined in jagged arms of strongly birefringent crystals, often in X forms, very characteristic.
	Bismuth iodide in dild sulfuric acid	volatility	Orange-red blades, usually pointed ends, often in rosettes; also with needles in branching aggregates; also red prisms.

(s) *Phosphotungstic acid soln.*—Dissolve 5 g  $P_2O_5 \cdot 24WO_3 \cdot xH_2O$  in 100 mL  $H_2O$ .

(t) *Picric acid.*—Crystals.

(u) *Picrolonic acid soln.*—Dissolve 250 mg 1-(*p*-nitrophenyl)-3-methyl-4-nitropyrrolone in 25 mL alcohol.

(v) *Platinic chloride soln.*—See 36.095(n).

(w) *Potassium cadmium iodide soln.*—See 36.095(o).

(x) *Potassium ferrocyanide soln.*—See 36.095(p).

(y) *Silicotungstic acid soln.*—Dissolve 5 g  $4H_2O \cdot SiO_2 \cdot 12WO_3 \cdot 22H_2O$  in 100 mL ca 6*N*  $H_2SO_4$ .

(z) *Silver nitrate soln.*—Dissolve 1 g  $AgNO_3$  in 20 mL  $H_2O$ .

(aa) *Sodium nitrite soln.*—Dissolve 10 g  $NaNO_2$  in  $H_2O$  and dil. to 100 mL.

(bb) *Zinc pyridine soln.*—Add 1 mL pyridine to soln of 1 g  $Zn(OAc)_2 \cdot 2H_2O$  in 20 mL  $H_2O$ .

**Table 36:06 Characteristics of Microchemical Tests for Synthetics**

Synthetic	Solvent	Concentration of Synthetic	Reagent	Description of Tests and Crystals
Acetanilid (63)	HCl (1+3)	1:100	Phosphotungstic acid	Rosettes of prisms.
	HCl (1+3)	1:100	Bromide-bromate soln	Small prisms.
Aminopyrine (65)	$H_2O$	1:100	Mercuric chloride Potassium cadmium iodide	Long, slender, radiating crystals, often curved. Groups of spiny branches.
Amobarbital (54)	$NH_4OH$ (1+9)	1:50	Acetic acid	Long, branching needles; some hexagonal plates in groups.
	$NH_4OH$ (1+9)	1:25	Acetic acid	Groups of rectangular plates.
Antipyrine (66)	$H_2O$	1:100	Potassium ferrocyanide	Add 1 drop HCl (1+39). Acicular and prismatic crystals form.
Aspirin (Acetylsalicylic acid) (64)	2% triethanolamine	1:50	Silver nitrate	Fine, curling, hair-like crystals form first near edge of drop.
Barbital (54)	—	Approx. 1 mg powder	Ammoniacal silver nitrate	Stir to aid soln and crystn. Very small, twined crystals and larger tufts.
	$NH_4OH$ (1+9)	1:50	Acetic acid	Dark burrs (stirring hastens crystn).
Benzocaine (Ethyl aminobenzoate) (67)	0.1 <i>N</i> HCl	1:100	Potassium ferrocyanide	Colorless, irregular plates and rods.
Benzoic acid (64)	—	Dry powder	Lead triethanolamine	Stir small amt of synthetic into 1 drop reagent. Stir thoroly to induce crystn. 4-sided plates, singly and in groups.
	—	Dry powder	Zinc pyridine	Stir small amt of synthetic into 1 drop reagent. Stir thoroly to induce crystn. Hexagonal crystals.
	2% triethanolamine	1:100 to 1:200	Silver nitrate	Rods or curving blades with irregular ends.
Cinchophen (67)	0.1 <i>N</i> NaOH. Add $H_2O$ and make slightly acid with HCl	1:1000	Gold chloride	Dark clusters of needles. Few short, rhombic crystals.
Diallylbarbituric acid (68)	—	Dry powder	Lead triethanolamine	Stir small amt of synthetic into 1 drop reagent. Rods singly and in clusters.
	—	Dry powder	Barium hydroxide	Stir small amt of synthetic into 1 drop reagent. Rods singly and in groups.
Dinitrophenol (65)	Small amt of 0.1 <i>N</i> NaOH	1:100	HCl	Plates with 4 branches. In more dil. soln, single rectangular plates.
Diphenhydramine hydrochloride (69)	Glycerol-alcohol (1+1) or $H_2O$	Approx. 0.2 mg powder or tablet material or 1:100	Platinic chloride	Aggregates of platy crystals form readily in glycerol-alcohol, gradually in $H_2O$ . Plates with jagged edges, tendency to twin, forming X-shaped aggregates, hour-glass forms, and dendritic structures. First order gray polarization colors; symmetrical or parallel extinction. Plates show pos. elongation.
Hydrochlorothiazide (71)	5% NaOH	—	Iodine-potassium iodide, 36.098	Burrs, with iodine-colored centers and highly birefringent peripheral blades or dichroic rods, iodine-colored to colorless <sup>a</sup>

(Continued)

Table 36:06 Characteristics of Microchemical Tests for Synthetics—Continued

Synthetic	Solvent	Concentration of Synthetic	Reagent	Description of Tests and Crystals
8-Hydroxyquinoline sulfate (67)	Dissolve salt in H <sub>2</sub> O. Dissolve free base in HCl (1+3), avoiding excess	1:500	Magnesia mixt.	Small, elliptical grains. Few burr-shaped crystals on standing.
Mandelic acid (68)	H <sub>2</sub> O	1:100	Lead acetate	Rosettes of thin, curving plates.
	H <sub>2</sub> O	1:100	Mercurous nitrate	Burr-shaped groups of needles.
Methenamine (66)	H <sub>2</sub> O	1:500	Silicotungstic acid	Thin, transparent, rectangular crystals.
Neocinchophen (63)	HCl (1+3)	Satd soln	Ammonium thiocyanate	Rosettes of needles. (Gentle agitation by tipping slide back and forth hastens crystn.)
	HCl (1+3)	Satd soln	Platinic chloride	Needles in clusters.
Pentylentetrazol (70)	H <sub>2</sub> O	—	Mercuric chloride (1:10)	Rods, many almost needle-like; frequency in groups; also in radiating aggregates.
	H <sub>2</sub> O	1:100	Silicotungstic acid	Amorphous, changes to elongated prisms; also long needles.
Phenacetin (Acetophenetidin (63)	—	Approx. 1 mg powd material	HNO <sub>3</sub>	Add 1 drop HNO <sub>3</sub> , let stand few sec, then add 1 drop H <sub>2</sub> O. Bright yellow, curving, branched crystals.
	HCl (1+3)	Satd soln	Iodine-potassium iodide	Large, irregular plates.
Phenazopyridine.HCl (67)	Dissolve salt in H <sub>2</sub> O. Dissolve free base in HCl (1+3), avoiding excess	1:1000	Ammonium thiocyanate	Small, red-brown, dense sheaves.
Phenobarbital (54)	—	Approx. 1 mg powder	Ammoniacal nickel acetate	Stir to aid soln and crystn. Single rectangular crystals.
Pyrimidine maleate (69)	Glycerol-alcohol (1+1) or H <sub>2</sub> O	1:1000 or ca 0.1 mg powder	Platinic chloride	Needles in rosette aggregates, sheaves, and singly. Needles show second order blue and green, and first order red and yellow polarization colors; parallel extinction and neg. elongation.
Salicylic acid (64)	HCl (1+3)	Dry powder	Bromide-bromate soln	Stir few crystals into 1 drop of the HCl. Add 1 drop reagent. Fine needles appear to grow from the crystals of salicylic acid.
	—	Dry powder	Lead triethanolamine	Stir few crystals into 1 drop reagent. Rods or needles grow from the crystals of salicylic acid.
	2% triethanolamine	1:100 to 1:200	Silver nitrate	Small, irregular plates; few short rods.
Sulfadiazine (49)	H <sub>2</sub> O	—	Gold bromide in HCl	Red, circular masses composed of fine needles.
Sulfanilamide (68)	—	Dry powder	Benzaldehyde	Thoroughly stir small amt into 1 drop reagent. 4-sided plates.
	0.1N HCl	Satd soln	Sodium nitrite	Yellow needles.
Sulfapyridine (52)	Acetone + H <sub>2</sub> O	—	Gold chloride	Yellow rods or blades; also X-shaped aggregates.
Sodium sulfapyridine monohydrate (52)	H <sub>2</sub> O	1:100	Gold chloride	Yellow rods in X-shaped aggregates.
Sulfathiazole (70)	50% alcohol	—	Picric acid	Long, fine, yellow needles, many curved, occur in dense rosettes; also short, stout rods in groups or singly.
	50% alcohol (or no solv.)	—	Picolonic acid	Distinct rosettes of very fine needles; also single needles.
Triethanolamine (66)	H <sub>2</sub> O	1:100	Bismuth iodide	Oily globules changing to large, red, hexagonal plates and prismatic crystals.
Tripeleminamine hydrochloride (69)	Glycerol-alcohol (1+1) or H <sub>2</sub> O	1:1000 or ca 0.1 mg powder or tablet material	Platinic chloride	Small needles and bladed crystals in dense rosette aggregates and singly. Needles show first order white and yellow polarization colors, parallel extinction, and pos. elongation.

<sup>a</sup> Official First Action.

**For Xanthine Group Alkaloids (60)  
Official First Action**

**36.103****Reagents**

(a) *Bismuth iodide soln.*—See 36.095(d)(2).

(b) *Gold bromide in dilute hydrochloric acid.*—Dissolve 1 g  $\text{HAuCl}_4 \cdot 3\text{H}_2\text{O}$  in 1.5 mL 40% HBr and add HCl (1+3) to make 45 mL.

(c) *Iodine-potassium iodide soln (5-14).*—Dissolve 5 g I and 14 g KI in  $\text{H}_2\text{O}$  and dil. to 100 mL with  $\text{H}_2\text{O}$ .

**36.104****General Test**

(Murexide reaction)

To small amt of substance in small porcelain crucible add very small crystal  $\text{KClO}_3$  and 1 drop HCl (1+1). Set on hot plate at ca 100°, or hot enough to boil off  $\text{H}_2\text{O}$  in short time. Soon after drying, residue becomes orange to red. Add 1 drop  $\text{NH}_4\text{OH}$ . Purple color is produced in presence of caffeine, theobromine, theophylline, and related xanthine derivatives.

**36.105****Identification**

(a) *Bismuth iodide soln.*—Add 1 drop reagent to little dry material on slide and cover.

(b) *Gold bromide in dilute hydrochloric acid.*—Place 1 drop reagent beside very small amt of dry substance on slide and apply cover glass so that reagent flows over substance.

(c) *Iodine-potassium iodide soln (5-14).*—In depression of cavity slide dissolve little of substance in small drop 1% NaOH soln and stir in excess  $\text{NaHCO}_3$  (some undissolved). Add large drop reagent and stir slightly. Add several crystals KCl. Examine center and edge as soln evaps.

See Table 36.07.

**Optical-Crystallographic Examination of Crystalline  
Substances (72)—Official Final Action**

(General knowledge of microscopy and crystallography is necessary for application of this technic. Some of std works on this subject are listed in Selected References (72). Optical-crystallographic properties of antihistamines, alkaloids, antibiotics, barbiturates, hallucinogens, steroids, sulfonamides, sympathomimetic amines and tranquilizers are given in Tables 52.024 and 52.025.)

**36.106****Apparatus**

(a) *Polarizing microscope.*—Fitted with polarizing prisms below and above rotating, graduated circular stage and with

accessories (Bertrand lens or pinhole eyepiece, first order red or quartz wedge compensators) for observation of interference figures, optic sign, and sign of elongation.

(b) *Refractometer.*—For measuring refractive indices of liqs at 20° or 25° from 1.300 to 1.840 with precision of  $\pm 0.0005$ .

**36.107****Reagents**

*Immersion media.*—Ideally immersion media for refractive index detn should have same color and intensity of color as substance being examined and be chemically stable. Refractive indices should not vary perceptibly with ordinary changes of temp. with exception of special liqs used in index-variation methods. Permanent set of liqs covering range 1.430–1.790 in 0.005 intervals made with following mixts is useful for both inorg. and org. substances:

Mixture	$n_D(20^\circ)$
Kerosene and mineral oil	1.435–1.480
Mineral oil and $\alpha$ -monochloronaphthalene	1.485–1.640
$\alpha$ -Monochloronaphthalene and methylene iodide	1.645–1.740
Methylene iodide and sulfur	1.740–1.790

Substances sol. in these liqs require prep special set of liqs.

**36.108****Determinations**

*Refractive indices.*—Det. refractive indices by mounting cryst. material in suitable immersion liqs and observing Becke line. Successively suspend crystals or crystal fragments of substance in immersion liqs of known refractive indices. Greater the difference between refractive indices of crystal and liq., the more prominently one stands out in bold relief from other. By repeatedly mounting such crystals in oils of successively lower or higher index, ultimately zone of contact of crystal and liq. becomes practically invisible, demonstrating that refractive indices of liq. and solid have been matched.

In case of substances crystg in isometric (cubic) system, there is only 1 refractive index, designated by  $n$ . Such substances are not doubly refractive when examined with crossed nicols. Substances crystg in other systems, hexagonal, tetragonal, monoclinic, triclinic, and orthorhombic, in ideal cases, have  $>1$  measurable refractive index. With uniaxial substances such as those crystg in hexagonal and tetragonal systems, 2 significant indices can be detd, designated as  $n_e$  and  $n_o$ . Substances crystg in monoclinic, triclinic, and orthorhombic systems, in ideal cases, have 3 refractive indices, designated as  $n_\alpha$ ,  $n_\beta$ , and  $n_\gamma$ .

**Table 36.07 Characteristics of Microchemical Tests for Xanthine Alkaloids**

Alkaloid	Reagent	Description of Crystals
Caffeine	Gold bromide in dil. HCl	Outer part: brownish needles with bright white birefringence. Inner part: small rods to sticks, little grains and plates with weak yellow birefringence.
	Bismuth iodide	Small brownish orange rods or blades growing from sample or nearby in rosettes; also some orange grains.
	Iodine-potassium iodide (5-14)	Grains, dark red to black, sometimes yellow or orange-brown; generally sq or cubical; birefringent with fairly strong light; some irregular dichroic blades.
Dyphylline	Gold bromide in dil. HCl	Needles, scattered and in rosettes; fairly bright birefringence.
	Bismuth iodide	Very small grains, flakes, blades in multitudes, birefringent.
	Iodine-potassium iodide (5-14)	Fuzzy brown dense rosettes thruout drop, birefringent around rims; excess reagent must be used; 5 min required to form crystals.
Theobromine	Gold bromide in dil. HCl	Grains or plates in dense groups; bright birefringence at edge of cluster.
	Bismuth iodide	Brown needles in rosettes.
	Iodine-potassium iodide (5-14)	Orange-brown chips; also rectangular plates with opposite sides incised; smaller crystals: grains, often lens shaped or diamonds; birefringent, somewhat dichroic.
Theophylline	Gold bromide in dil. HCl	Long needles in sheaves; fairly bright birefringence.
	Bismuth iodide	Grains and short prisms, often rectangular; brightly birefringent.
	Iodine-potassium iodide (5-14)	Black needles in rosettes around edge; birefringent; when larger, blades or rods, dichroic black vertically to yellow horizontally.

**Extinction and extinction angle of anisotropic substances.**—Anisotropic crystals, when rotated through 360° on stage, become dark 4 times. Positions of darkness are known as extinction positions and correspond to positions in which vibrations of birefringent rays produced by crystal are mutually parallel to vibration directions of polarizer and analyzer indicated by cross hairs in eyepiece. If crystal extinguishes when crystal edge or face is parallel to one of cross hairs, extinction is *parallel*. If bisector of silhouette angle is parallel to one of cross hairs, extinction is *symmetrical*. Crystals showing extinction differing from these 2 have *inclined* extinction. Measure extinction angles on those crystals showing inclined extinction by rotating crystal so that crystal edge or face is parallel to 1 of cross hairs. Rotate stage until crystal extinguishes. Read on stage vernier extinction angle between face or edge at extinction and nearest cross hair. Express extinction angles with relationship to principal vibration directions of light and crystallographic axes.

**Elongation.**—Many crystals are frequently elongated in 1 direction. Relationship between direction of elongation and vibration directions of slow and fast rays of anisotropic crystal is sometimes of determinative value. If substance is length slow, *i.e.*, slow ray or higher refractive index is parallel to direction of elongation, sign of elongation is pos.; if substance is length fast, sign is neg.

Sign of elongation (+ or −) is detd with gypsum plate and crossed nicols. A long and narrow crystal, showing very little color with crossed nicols, is so oriented that its long dimension is parallel to direction "z" of plate (slow ray) which is inserted in slit of microscope tube. (Direction "z" is indicated by arrow on plate.) If crystal appears blue or other color of higher order than red-violet due to plate, elongation is +; if crystal appears yellow, white, or gray, *i.e.*, of lower order color than red-violet field, elongation is −.

**Optic character and optic sign.**—Det. optic character (uniaxial or biaxial) and optic sign (+ or −), using first order red or quartz wedge compensators in conjunction with interference figures. Obtain interference figures from conoscopic images of crystals suitably oriented. In absence of interference figures, det. these properties from relationship of principal refractive indices. When  $(n_\beta - n_\alpha)$  is  $< (n_\gamma - n_\beta)$ , optic sign is +. When  $(n_\beta - n_\alpha)$  is  $> (n_\gamma - n_\beta)$ , optic sign is −.

**Optic axial angle (2V).**—Calc. axial angle (2V) from values of 3 refractive indices (here designated  $\alpha$ ,  $\beta$ , and  $\gamma$ ) according to formulas:

$$\cos^2 V_\alpha = \frac{\gamma^2(\beta^2 - \alpha^2)}{\beta^2(\gamma^2 - \alpha^2)} \text{ (for } - \text{ optic sign), or}$$

$$\cos^2 V_\gamma = \frac{\alpha^2(\gamma^2 - \beta^2)}{\beta^2(\gamma^2 - \alpha^2)} \text{ (for } + \text{ optic sign),}$$

where  $2V_\alpha$  is axial angle about  $\alpha$ , and  $2V_\gamma$  is axial angle about  $\gamma$ . Alternatively, est. approx. value of 2V from curvature of isogyre referring to diagrams of substances with known angles. Angle ranges from small (0–25°, sharply curved) to medium (26–60°, moderately curved) to large (61–90°, nearly straight isogyre).

## 37. Drugs: Acidic

### ACIDS

#### Benzoic and Salicylic Acids—Official Final Action

##### 37.001 ★ *Titrimetric Method (1)* ★

(Applicable to ointments. *Caution:* See 51.011, 51.039, 51.040, 51.054, and 51.056.)

Extn of both acids from acid soln and titrn with std alkali. Bromination of salicylic acid with std  $\text{KBrO}_3$  and calcn of benzoic acid by difference. See 37.001, 12th ed.

#### Chromatographic Method (2)

##### 37.002

##### *Apparatus*

(a) *Chromatographic tubes.*—Fuse 6 cm length of 5–6 mm tubing to piece of 25 mm tubing ca 25 cm long (25 × 200 mm test tube may be used). Constrict stem slightly ca 2 cm below seal. Com. tubes with dimensions  $\pm 10\%$  are satisfactory. Pack wad of Pyrex glass wool in base as support.

(b) *Tamping rod.*—Flatten end of glass rod to circular head with clearance of ca 1 mm in tube (a). Or use disk of stainless steel, Al, etc., of diam. ca 1 mm less than id of column, (a), attached to 30–45 cm (12–18") rod.

##### 37.003

##### *Reagents*

(a) *Ferric chloride-urea soln.*—Dissolve, without heating, 18 g reagent grade urea in 2.5 mL 60%  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  (available from MC/B Manufacturing Chemists) and 12.5 mL 0.05*N* HCl. Prep. fresh daily.

(b) *Phosphoric acid.*—30%. Dil. 30 mL 85%  $\text{H}_3\text{PO}_4$  to 85 mL with  $\text{H}_2\text{O}$ .

(c) *Sodium bicarbonate.*—1*N*. Dissolve 2.5 g  $\text{NaHCO}_3$  in 30 mL  $\text{H}_2\text{O}$ . Use only freshly prepd soln.

(d) *Diatomaceous earth.*—See 36.002.

(e) *Benzoic acid std soln.*—Accurately weigh 40–100 mg benzoic acid (depending on concn benzoic acid in sample), dissolve in  $\text{CHCl}_3$ , and dil. to 100 mL with  $\text{CHCl}_3$ . Shortly before use, transfer 5 mL to 50 mL vol. flask; add 4 drops HCl, 1 mL HOAc, 5 mL ether, and 7 mL MeOH; and dil. to vol. with  $\text{CHCl}_3$ .

(f) *Salicylic acid std soln.*—Dissolve 50 mg salicylic acid in  $\text{CHCl}_3$  and dil. to 100 mL. Transfer 5 mL to 100 mL vol. flask; add 2 drops HCl, 2 mL HOAc, 10 mL MeOH, and 20 mL ether; and dil. to vol. with  $\text{CHCl}_3$ .

##### 37.004

##### *Preparation of Sample*

(a) *Ointments.*—Dissolve ca 1 g sample, accurately weighed, in  $\text{CHCl}_3$  and dil. to 100 mL. If necessary, dil. aliquot to prep. final soln contg 0.15–0.25 mg salicylic acid/mL  $\text{CHCl}_3$ .

(b) *Liquids.*—Dil. aliquot of liq. contg 150–250 mg salicylic acid to 100 mL with MeOH. Dil. 10 mL methanolic soln to 100 mL with  $\text{CHCl}_3$ .

##### 37.005

##### *Preparation of Columns*

*Column I.*—*Lower stage:* mix 1 g diat. earth with 0.5 mL 30%  $\text{H}_3\text{PO}_4$  to uniform fluffy mixt. Transfer to tube and tamp to uniform mass with gentle pressure. *Upper stage:* Similarly mix 5 g diat. earth with 3 mL  $\text{FeCl}_3$  urea reagent. (Mix thoroly, as nonuniform column may cause difficulty in elution of salicylic acid.) Transfer to tube directly above  $\text{H}_3\text{PO}_4$  layer. Cover with glass wool.

*Column II.*—Mix 2 g diat. earth with 1 mL freshly prepd 1*N*  $\text{NaHCO}_3$  soln.

##### 37.006

##### *Determination*

(Use  $\text{H}_2\text{O}$ -satd solvs.)

Mount *Column I* directly above *Column II*. Pipet 10 mL dild sample into small beaker. Pour onto upper column, washing beaker with 10 mL  $\text{CHCl}_3$  in small portions. Let sample sink into column and wash column with 75 mL  $\text{CHCl}_3$ . If purple salicylic acid band reaches  $\text{H}_3\text{PO}_4$  layer, repeat with smaller sample. Sep. columns and wash *Column II* with 50 mL ether. Discard wash. Elute *Column I* into 100 mL vol. flask (contg 10 mL MeOH and 2 drops HCl) with 2 mL HOAc in 20 mL ether followed by enough 1% HOAc in  $\text{CHCl}_3$  to bring to vol. Measure *A* of eluate and salicylic acid std at max., ca 306 nm, and calc. concn salicylic acid.

Elute *Column II* into 50 mL vol. flask (contg 7 mL MeOH and 4 drops HCl) with 0.5 mL HOAc in 5 mL  $\text{CHCl}_3$  followed by enough 1% HOAc in  $\text{CHCl}_3$  to bring to vol. Measure *A* of eluate and benzoic acid std at max., ca 275 nm, and calc. concn benzoic acid.

##### 37.007 ★ *Salicylic Acid in Presence of Other Phenols (3)*—Official Final Action ★

See 32.184–32.185, 10th ed. (*Caution:* See 51.011, 51.040, and 51.056.)

#### Mandelic Acid (4)—Official Final Action

##### 37.008

##### *Qualitative Tests*

(Applicable to free acid)

See Microchemical Tests, Table 36:06.

##### 37.009

##### *Determination*

(*Caution:* See 51.011, 51.039, 51.040, 51.054, and 51.056.)

(a) *Tablets.*—Weigh amt of powd sample contg 0.4–0.5 g mandelic acid and transfer to separator contg 10 mL  $\text{H}_2\text{O}$ . Acidify with HCl (1+3) and add 2 mL excess. Ext with six 20 mL portions  $\text{CHCl}_3$ -ether (2+1); wash each portion in second separator with 2 mL  $\text{H}_2\text{O}$ , and pass soln thru cotton plug, previously satd with solv., into 250 mL beaker. Wash outer surface of separator stem with few mL solv. and add to main portion. Test for complete extn with 15 mL addnl solv. and evap. in sep. beaker. Wash any residue thus obtained into beaker contg main ext with few mL solv. Evap. to dryness at  $\leq 40^\circ$  with aid of air current. Dissolve residue in 25 mL  $\text{CO}_2$ -free  $\text{H}_2\text{O}$ , 50.033(a), and titr. with 0.1*N* NaOH, using phthln. 1 mL 0.1*N* NaOH = 0.01522 g mandelic acid ( $\text{C}_6\text{H}_5\text{CHOHCOOH}$ ); 0.01692 g  $\text{NH}_4$  mandelate, 0.01741 g Na mandelate, 0.01712 g Ca mandelate, and 0.01633 g Mg mandelate.

After titrn, mandelic acid may be re-extd and ext used for mp detns or qual. tests.

(b) *Liquid preparations.*—Measure 1 mL sample, or aliquot of diln contg 0.4–0.5 g mandelic acid, into separator and acidify with HCl (1+3). Proceed as in (a).

★ Surplus method—see inside front cover.

## ANTIPYRETIC DRUGS

## Acetaminophen (5)—Official Final Action

## 37.010

## Reagents

(a) *Bicarbonate-carbonate buffer*.—pH 10.1. Weigh 1.0 g  $\text{NaHCO}_3$  and 4.5 g  $\text{Na}_2\text{CO}_3$  into 100 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ .

(b) *Acidic methanol*.—1.0 mL 0.1N  $\text{HCl}$ /100 mL  $\text{MeOH}$ . Prep. enough to ensure same  $\text{MeOH}$  is used thruout for std and sample.

(c) *Diatomaceous earth*.—See 36.002.

(d) *Acetaminophen std soln*.—0.008 mg/mL. Accurately weigh 40 mg acetaminophen std into 100 mL vol. flask. Dil. to vol. with acidic  $\text{MeOH}$  and mix well. Transfer 2.0 mL to 100 mL vol. flask and dil. to vol. with acidic  $\text{MeOH}$ .

## 37.011

## Preparation of Sample

(a) *Sirup*.—Transfer 15.0 mL 0.1N  $\text{NaOH}$  to 25 mL vol. flask. Dil. to vol. with acetaminophen sirup, avoiding wetting flask neck above graduation mark while adding sirup, and mix. Transfer 10.0 mL of this diln to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

(b) *Tablets*.—Det. av. wt/tablet and pulverize. Accurately weigh portion of powder contg ca 240 mg acetaminophen and transfer to 250 mL vol. flask. Add 2 mL 1.0N  $\text{NaOH}$  and ca 100 mL  $\text{H}_2\text{O}$ . Shake, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

## 37.012

## Preparation of Chromatographic Column

Pack fine glass wool plug in base of chromatgc tube (25 × 250 mm) with aid of tamping rod ca 45 cm long and having disk with diam. ca 1 mm less than tube. To 3.0 g diat. earth, add 2.0 mL buffer soln and mix until fluffy. Transfer mixt. to column and tamp gently to compress to uniform mass. Transfer 2.0 mL sample soln to 100 mL beaker, add 1 drop  $\text{HCl}$ , and mix. Add 3.0 g diat. earth, mix thoroly, and transfer to column. Scrub beaker with 1 g diat. earth and 2 drops  $\text{H}_2\text{O}$ . Transfer to column, tamp, and top with fine glass wool pad.

## 37.013

## Determination

(Caution: See 51.011, 51.039, and 51.054.)

(Use  $\text{H}_2\text{O}$ -washed solvs thruout.)

Pass 100 mL  $\text{CHCl}_3$  thru column and discard eluate. Elute acetaminophen with 150 mL ether, collecting eluate in 400 mL beaker. Evap. soln to dryness on steam bath under air stream. Dissolve residue in acidic  $\text{MeOH}$ , transfer quant. to 50 mL vol. flask, and dil. to vol. with same solv. Transfer 10.0 mL of this soln to 50 mL vol. flask, dil. to vol. with acidic  $\text{MeOH}$ , and mix. Scan spectra of sample and std solns from 350 to 240 nm in 1 cm cells, using acidic  $\text{MeOH}$  as blank.

mg Acetaminophen in portion of sirup or tablet taken

$$= 31.25 \times C \times (A/A')$$

where  $C$  = mg/mL std soln, and  $A$  and  $A'$  refer to sample and std, resp., at max., ca 249 nm.

## Acetaminophen and Salicylamide (6)—Official Final Action

(Applicable in presence of antihistamines, barbiturates, caffeine, ascorbic acid, prednisone, and belladonna alkaloids. Aspirin interferes in salicylamide detn.)

## 37.014

## Apparatus

(a) *Chromatographic tube*.—Plain, 250 × 25 mm i.d.

(b) *Tamping rod*.—See 37.002(b); use for packing columns.

(c) *UV spectrophotometer*.—Preferably recording, with matched 1.0 cm cells.

(d) *Infrared spectrophotometer*.—With equipment suitable for prep KBr disks.

## 37.015

## Reagents

(a) *Tripotassium phosphate*.—20%. Dissolve 10.0 g  $\text{K}_3\text{PO}_4$  in  $\text{H}_2\text{O}$  and dil. to 50 mL.

(b) *Water-washed chloroform*.—Shake equal vols  $\text{CHCl}_3$  and  $\text{H}_2\text{O}$  in separator 1 min. Use within 1 day.

(c) *Water-washed ethyl acetate*.—Shake equal vols  $\text{EtOAc}$  and  $\text{H}_2\text{O}$  in separator 1 min. Discard lower phase.

(d) *Acetic acid in chloroform*.—(1) 10%.—Dil. 10.0 mL  $\text{HOAc}$  to 100 mL with  $\text{CHCl}_3$ . (2) 1%.—Dil. 10.0 mL 10% soln to 100 mL with  $\text{CHCl}_3$ . Prep. ca 375 mL for each sample and 225 mL for std solns.

(e) *Diatomaceous earth*.—See 36.002.

(f) *Acetaminophen std soln*.—0.6 mg/100 mL. Accurately weigh ca 60 mg USP Ref. Std Acetaminophen; dissolve and dil. with alcohol in 100 mL vol. flask. Dil. 10.0 mL of this soln to 100 mL with alcohol. Dil. 10.0 mL of second diln to 100 mL with alcohol.

(g) *Salicylamide std soln*.—2 mg/100 mL. Accurately weigh ca 50 mg USP Ref. Std Salicylamide; dissolve and dil. with 1%  $\text{HOAc-CHCl}_3$  in 100 mL vol. flask. Dil. 4.0 mL of this soln to 100 mL with 1%  $\text{HOAc-CHCl}_3$ .

## 37.016

## Preparation of Sample

Det. av. wt of tablets or capsules, reduce to powder passing No. 60 sieve.

## 37.017

## Preparation of Columns

*Column I*.—Place small piece of glass wool in chromatgc tube. Mix 1.0 g diat. earth, (e), and 0.5 mL  $\text{HCl}$  (1+1) in beaker until fluffy, and pack in tube. Accurately weigh portion powd sample contg ca 50 mg acetaminophen into 100 mL beaker and thoroly wet with 2.0 mL  $\text{HCl}$  (1+1). Add 3.0 g diat. earth, mix until fluffy, transfer quant. to column, and pack. Scrub sample beaker with 1.0 g diat. earth and 0.5 mL  $\text{HCl}$  (1+1), and pack on column. Wipe all utensils and sample beaker with glass wool and pack on column.

*Column II*.—Place small piece of glass wool in chromatgc tube. Mix 3.0 mL 20%  $\text{K}_3\text{PO}_4$  and 5.0 g diat. earth until fluffy, and pack on column. Cover diat. earth with small piece of glass wool.

## 37.018

## Determination

Mount columns so that I elutes into II. Place waste beaker under column II. Add 100 mL  $\text{H}_2\text{O}$ -washed  $\text{CHCl}_3$  to column I. After all  $\text{CHCl}_3$  has passed thru both columns, sep. columns, rinsing stem of top column with 5 mL  $\text{H}_2\text{O}$ -washed  $\text{CHCl}_3$  into bottom column. Elute column II with addnl 25 mL  $\text{H}_2\text{O}$ -washed  $\text{CHCl}_3$ . Rinse stem of column II with  $\text{CHCl}_3$  after all  $\text{CHCl}_3$  has passed thru. Discard wash  $\text{CHCl}_3$ .

Place 250 mL vol. flasks under each column. Elute acetaminophen from column I with 100 mL  $\text{H}_2\text{O}$ -washed  $\text{EtOAc}$ . Do not let column run dry until entire 100 mL has passed into column. Rinse column stem with  $\text{EtOAc}$  (not  $\text{H}_2\text{O}$ -washed) into flask. Add 5 mL alcohol, mix, and dil. to vol. with  $\text{EtOAc}$  (not  $\text{H}_2\text{O}$ -washed). Pipet 15 mL into 50 mL vol. flask and dil. to vol. with  $\text{EtOAc}$  (not  $\text{H}_2\text{O}$ -washed). Pipet 10 mL of this soln into 100 mL beaker and evap. to dryness with gentle air current. Do not use heat. Dissolve residue in alcohol and transfer quant. to 100 mL vol. flask with several portions alcohol; dil. to vol. with alcohol. Det.  $A$  of sample and std, (f), solns at 248 nm in 1.0 cm cell against

alcohol as ref. If recording spectrophtr is available, scan soln from 320 to ca 210 nm in 1.0 cm cells against alcohol.

mg Acetaminophen in portion sample taken

$$= 83.33(A/A') \times C,$$

where  $A$  and  $A'$  refer to sample and std solns, resp., at 248 nm; and  $C$  = exact concn of ref. std soln in mg/100 mL final soln.

Elute salicylamide from column // by passing 10.0 mL 10% HOAc-CHCl<sub>3</sub> thru column, followed by 100 mL 1% HOAc-CHCl<sub>3</sub>. After complete elution, rinse stem of column into flask with 1% HOAc-CHCl<sub>3</sub> and dil. to vol. with same solv. Pipet aliquot contg ca 2 mg salicylamide into 100 mL vol. flask and dil. to vol. with 1% HOAc-CHCl<sub>3</sub>. Det.  $A$  of sample and std, (g), solns at 308 nm in 1.0 cm cells against 1% HOAc-CHCl<sub>3</sub> as ref. If recording spectrophtr is used, scan solns from 370 to ca 260 nm in 1.0 cm cells against 1% HOAc-CHCl<sub>3</sub>.

mg Salicylamide in portion sample taken

$$= (250/B) \times (A/A') \times C,$$

where  $B$  = vol. (mL) aliquot taken to contain 2 mg salicylamide;  $A$  and  $A'$  refer to sample and ref. std solns, resp., at 308 nm; and  $C$  = exact concn of ref. std soln in mg/100 mL final soln.

### 37.019

#### Identification

Prep. KBr disks of each ingredient from eluates by evapg, with gentle air current only, aliquot contg ca 1 mg each ingredient. Be sure no detectable odor of HOAc is present from salicylamide aliquot before prep KBr disk.

Compare IR spectrum of each with its respective std from 2.0  $\mu$ m (5000 cm<sup>-1</sup>) to 15  $\mu$ m (660 cm<sup>-1</sup>).

### Acetophenetidin, Acetylsalicylic Acid, and Caffeine (APC)—Official Final Action

(For antihistamines in combination with APC—See 38.136.)

### 37.027 ★ Method I (For Acetylsalicylic Acid Only) (12) ★

CHCl<sub>3</sub> extn, hydrolysis to salicylic acid, and pptn as tetraiodophenylenequinone. See 36.190, 11th ed.

### 37.028 ★ Method II (13) ★

Removal of acetylsalicylic acid with NaHCO<sub>3</sub> soln. Gravimetric detn of most of acetophenetidin from dil. H<sub>2</sub>SO<sub>4</sub>, hydrolysis of remaining acetophenetidin to phenetidin sulfate, extn of caffeine, and regeneration of residual acetophenetidin. See 36.191–36.192, 11th ed.

#### Chromatographic Method (14)

### 37.029

#### Reagents

(a) *Sodium bicarbonate soln*.—1M. Dissolve 4.2 g NaHCO<sub>3</sub> in 48 mL H<sub>2</sub>O.

(b) *Washed ether*.—Wash USP ether with equal vol. H<sub>2</sub>O in separator. Filter thru paper, rejecting first 15 mL. Use within 3 days. Approx. 70 mL required for each sample.

(c) *Chloroform*.—USP.  $A$  against H<sub>2</sub>O at 276 nm  $\leq$ 0.050. Use same lot thruout.

(d) *Washed chloroform*.—Wash and filter CHCl<sub>3</sub> as in (b). Use within 3 days. Use same lot thruout. Approx. 700 mL is required for stds and 170 mL for each sample.

(e) *Isooctane*.— $A$  against H<sub>2</sub>O at 286 nm  $\leq$ 0.050. Use same lot thruout.

(f) *Acetophenetidin std soln*.—7 mg/100 mL. Dissolve 70.0 mg pure acetophenetidin in CHCl<sub>3</sub> and dil. to 100 mL with CHCl<sub>3</sub>. Dil. 10 mL aliquot to 100 mL with isooctane.

(g) *Caffeine std soln*.—1.4 mg/100 mL. Dissolve 140.0 mg caffeine in washed CHCl<sub>3</sub> and dil. to 100 mL. Dil. 10 mL aliquot to 100 mL; dil. 10 mL aliquot of this soln to 100 mL with washed CHCl<sub>3</sub>.

(h) *Acetylsalicylic acid std soln*.—5 mg/100 mL. Dissolve 100.0 mg acetylsalicylic acid in washed CHCl<sub>3</sub> and dil. to 100 mL. To 5 mL aliquot add 1.0 mL HOAc and dil. to 100 mL with washed CHCl<sub>3</sub>. Prep. fresh daily.

(i) *Salicylic acid std soln*.—2.5 mg/100 mL. Dissolve 100.0 mg salicylic acid in washed CHCl<sub>3</sub> and dil. to 100 mL. Dil. 25 mL aliquot to 100 mL; to 10 mL aliquot of this soln, add 1.0 mL HOAc and dil. to 100 mL with washed CHCl<sub>3</sub>.

### 37.030

#### Apparatus

See 37.002.

### 37.031

#### Preparation of Sample

Weigh powd sample contg ca 100 mg acetylsalicylic acid and transfer to 100 mL vol. flask. Add 60 mL CHCl<sub>3</sub> and shake well. Add 0.2 mL HOAc and dil. to vol. with CHCl<sub>3</sub>.

### 37.032

#### Preparation of Chromatographic Column

Loosely pack small amt of fine glass wool in base of chromatgc tube so as to support diat. earth, but not cause irregularity in thickness of diat. earth layer.

To 2.0 g diat. earth, **36.002**, in 100 mL beaker, or glass mortar, add 2.0 mL  $\text{H}_2\text{SO}_4$  (1+9). Mix well with metal spatula. Transfer to chromatgc tube, and with packing rod, compress lightly to uniform mass. Mix 2.0 g diat. earth with 2.0 mL 1M  $\text{NaHCO}_3$  and place in column above acid layer. Wash column with 15–20 mL washed ether and discard washings.

**37.033****Separation**

(Use washed ether and washed  $\text{CHCl}_3$  thruout, except for dissolving acetophenetidin residue.)

(a) *Acetophenetidin*.—Dil. 5 mL aliquot prepd sample soln with 20 mL ether and pass thru column, receiving eluate in 100 or 150 mL beaker. After soln has passed into adsorbent, wash with five 5 mL portions ether, letting each portion pass into adsorbent before adding next. Wash tip of outlet with  $\text{CHCl}_3$  and evap. total eluate to dryness by gentle heating on steam bath with air current. Dissolve acetophenetidin residue in 5 mL USP  $\text{CHCl}_3$  and dil. with isooctane to 50 mL.

(b) *Caffeine*.—Immediately after passage of last portion of ether thru column, replace beaker with 50 mL vol. flask. Pass 48 mL  $\text{CHCl}_3$  thru column, wash tip with  $\text{CHCl}_3$  and dil. eluate to vol.

(c) *Acetylsalicylic acid and salicylic acid*.—Immediately replace receiver with 100 mL vol. flask. Pass soln of 0.5 mL HOAc in 5 mL  $\text{CHCl}_3$  thru column, followed by 90–92 mL 1% soln of HOAc in  $\text{CHCl}_3$ . Wash tip with  $\text{CHCl}_3$  and dil. eluate to vol.

**37.034****Determination**

Immediately det. *A* of acid fraction and of acetylsalicylic and salicylic acid std solns at 280 and 310 nm against 1% HOAc in  $\text{CHCl}_3$ . Det *A* of acetophenetidin fraction and std at 286 nm against isooctane-USP  $\text{CHCl}_3$  (9+1) and that of caffeine fraction and std at 276 nm against washed  $\text{CHCl}_3$  blank.

Calc. amt of each ingredient in sample. Acetylsalicylic and salicylic acids may be calcd by successive approximations as follows: Attributing entire *A* at 310 nm to salicylic acid, use ratio of salicylic acid std readings at the 2 wavelengths to calc. *A* due to salicylic acid at 280 nm, and deduct from total *A* at 280 nm. Attributing remainder to acetylsalicylic acid, use ratio of acetylsalicylic acid std readings to calc. *A* due to acetylsalicylic acid at 310 nm. Deduct this *A* from total at 310 nm. Use remainder to calc. amt of salicylic acid in sample and also to recalc. *A* due to salicylic acid at 280 nm. Deduct latter from total *A* at 280 nm and use remainder to calc. amt of acetylsalicylic acid in sample. Alternatively, calc. these two ingredients by simultaneous equations. Amt of acetylsalicylic acid hydrolyzed may be calcd by multiplying amt of salicylic acid by 1.3044.

**37.045 ★ Combined Acetic Acid (21) ★**

See **36.210**, 11th ed.

**★ Double Titration Method (22) ★****37.046 Preparation of Solution**

(a) *Dry extraction method (applicable in all cases)*.—Treat weighed sample contg  $\geq 0.3$  g acetylsalicylic acid with small portions  $\text{CHCl}_3$ , filter into beaker, and wash residue with  $\text{CHCl}_3$  until completely extd. Evap. bulk of  $\text{CHCl}_3$  on steam bath, finishing with aid of elec. fan without heat.

(b) *Wet extraction method (applicable in absence of acids and alkalies, or alkaline earth carbonates)*.—Transfer accurately weighed sample contg  $\geq 0.3$  g acetylsalicylic acid to small separator contg ca 20 mL  $\text{H}_2\text{O}$ . Ext repeatedly with  $\text{CHCl}_3$ , using 30, 25, 20, 15, 10, and 5 mL portions, and test for completeness of extn by evapg portion of final ext on watch glass. Filter combined  $\text{CHCl}_3$  portions thru cotton, and wash funnel and cotton with  $\text{CHCl}_3$ . Evap. bulk of  $\text{CHCl}_3$  on steam bath, finishing with aid of elec. fan without heat.

(c) *Acetylsalicylic acid and uncoated tablets containing no excipient*.—Dissolve sample directly in 10 mL neut. alcohol.

**37.047****Determination**

Dissolve the dry  $\text{CHCl}_3$  ext in 10 mL neut. alcohol, and immediately and rapidly titr. with 0.1N alkali, using phthln. Use first persistent pink as end point, since any slight excess of alkali tends to hydrolyze ester quickly. Add vol. of the 0.1N alkali equal to that used in first titrn and then add 5 mL more. Heat on steam bath 15 min. Back-titr. with 0.1N acid. If product is pure, total vol. of alkali consumed will be twice that of first titrn. 1 mL 0.1N alkali consumed in 2 titrns = 0.0090 g acetylsalicylic acid.

★ Surplus method—see inside front cover.

**Acetylsalicylic Acid and Phenobarbital (23)**  
**Official Final Action**

**37.048****Apparatus**

- (a) *Spectrophotometer*.—Capable of isolating spectrum of  $\leq 2$  nm in region 230–300 nm.  
 (b) *Chromatographic tube and tamping rod*.—See 37.002.

**37.049****Reagents**

- (a) *Dibasic potassium phosphate soln*.—Approx. 2M. Dissolve 35 g  $K_2HPO_4$  in  $H_2O$ , cool to room temp., and dil. to 100 mL.  
 (b) *Diatomaceous earth*.—See 36.002.  
 (c) *Washed chloroform*.—Wash USP  $CHCl_3$  with  $\frac{1}{2}$  vol.  $H_2O$  in separator.  
 (d) *Acetylsalicylic acid std soln*.—5 mg/100 mL. Dissolve 100 mg acetylsalicylic acid in  $CHCl_3$  and dil. to 100 mL with  $CHCl_3$ . Dil. 5 mL aliquot to 100 mL with  $CHCl_3$ .  
 (e) *Phenobarbital std soln*.—1 mg/100 mL. Dissolve 100 mg phenobarbital in  $NH_4OH$  (1+27) and dil. to 500 mL with  $NH_4OH$  (1+27). Dil. 5 mL aliquot to 100 mL with  $NH_4OH$  (1+27).

**37.050****Preparation of Sample Solution**

Transfer accurately weighed portion of finely ground tablets contg 60–120 mg phenobarbital to 100 mL vol. flask. Dissolve in  $CHCl_3$  by shaking vigorously and dil. to vol. with  $CHCl_3$ .

**37.051****Preparation of Chromatographic Column**

Pack small pledget of glass wool in constricted portion of stem of tube and place pad of glass wool ca 5 mm thick in bottom of large portion of tube. Fasten piece of rubber tubing with attached screw clamp to outlet to limit flow during packing. Clamp tube in vertical position.

To 10 g diat. earth in mortar add 50 mL  $CHCl_3$ , and mix with pestle to form slurry. Distribute 10 mL 2M  $K_2HPO_4$  soln, (a), over surface of slurry and mix thoroly until homogeneous, adding more  $CHCl_3$  if necessary. Add this slurry to tube, ca  $\frac{1}{5}$  at time, alternately packing and forming flocculent suspension by working packing rod up and down. Diat. earth must be covered with  $CHCl_3$  at all times.

After column is packed, remove rubber tube from stem and rinse stem with  $CHCl_3$ . Check flow rate of column with  $CHCl_3$  level ca 5 cm above surface of column. Adjust rate of flow to 2–5 mL/min by tightening or loosening glass wool pledget in constricted portion of stem. When level of solv. just reaches surface of column, place 100 mL vol. flask under stem.

**37.052****Determination of Phenobarbital**

Add 5 mL prep'd sample soln, 37.050, from pipet to side of tube near diat. earth surface. When level of sample soln reaches surface of column, add 5 mL washed  $CHCl_3$ , let sink into column, and repeat with another 5 mL washed  $CHCl_3$ . After last rinse enters column, add washed  $CHCl_3$  to tube and keep level of 4–8 cm  $CHCl_3$  above column during elution.

Collect 95 mL eluate in the 100 mL vol. flask. Dil. to vol. with  $CHCl_3$ , mix, and transfer 20 mL aliquot to 100 mL beaker. Evap. to dryness on steam bath under air current. Dissolve residue in  $NH_4OH$  (1+27) and transfer to 100 mL vol. flask. Rinse, and dil. to vol. with  $NH_4OH$  (1+27). Det.  $A$  at max., ca 240.5 nm, against blank prep'd by passing 5 mL  $CHCl_3$  thru column as with sample soln.

$$g \text{ Phenobarbital in sample} = 10A/a,$$

where  $a$  is absorptivity of phenobarbital at 240.5 nm obtained by dividing  $A$  of std phenobarbital soln in 1 cm cell at 240.5 nm by its concn (0.01 g/L).

**37.053****Determination of Acetylsalicylic Acid**

Dil. 5 mL original sample soln, 37.050, to 100 mL with  $CHCl_3$  in vol. flask. Dil. 10 mL aliquot of this soln to 100 mL with  $CHCl_3$ . Det.  $A$  of final diln on spectrophtr at 278 nm against  $CHCl_3$  blank.

$$g \text{ Acetylsalicylic acid in sample} = 20A_{278}/a_{278},$$

where  $a_{278}$  is absorptivity of acetylsalicylic acid at 278 nm obtained by dividing  $A$  of std acetylsalicylic acid soln in 1 cm cell at 278 nm by its concn (0.05 g/L).

**37.054 ★ Acetylsalicylic Acid and Phenolphthalein ★**  
**in Tablets (24)—Official Final Action**

(Caution: See 51.011, 51.039, 51.040, 51.054, and 51.056.)

Accurately weigh powd sample, prep'd as in 36.003, contg 0.05–0.1 g phthln. Ext repeatedly with 20 mL portions ether, and filter into separator. Test for complete extn (5–8 extns required).

(a) *Acetylsalicylic acid*.—Shake ether soln,  $\geq 1$  min each time, with two 20 mL portions 4%  $NaHCO_3$  soln (temp.  $\leq 20^\circ$ ). Transfer soln to second separator. Wash ether with two 10 mL portions  $H_2O$  and add to  $NaHCO_3$  soln. Ext  $NaHCO_3$  soln with 20 mL ether. Drain lower aq. layer into 100 mL vol. flask. Wash ether with small portions  $H_2O$ , rinse into flask, and dil. to vol. Add wash ether to bulk of solv. in original separator. Reserve ether soln for detn of phthln.

Transfer aliquot  $NaHCO_3$  soln contg  $\geq 0.3$  g acetylsalicylic acid to separator. (Acid must be sepd from  $NaHCO_3$  soln as rapidly as possible to prevent hydrolysis.) Acidify with  $HCl$  (1+3) and ext liberated acetylsalicylic acid with 30, 20, 20, 10, and 10 mL portions  $CHCl_3$ -ether (3+2). Wash each ext with 2 mL  $H_2O$  in second separator and filter thru cotton pledget, moistened with  $CHCl_3$ -ether mixt., into counterpoised weighed beaker. Test for complete extn. Evap. filtrate to 10–15 mL on  $H_2O$  bath, and complete evapn without heat. Dry residue to const wt at room temp. Wt may be checked by double titrn method, 37.047.

(b) *Phenolphthalein*.—Ext original ether soln with 20 mL portions 3%  $NaOH$  soln until all phthln is removed (indicated by color). Transfer these alk. exts to second separator, acidify with  $HCl$  (1+3), and ext with  $CHCl_3$ -ether (3+2). Wash each ext in third separator with 2 mL  $H_2O$  to which has been added 1 or 2 drops  $HCl$  (1+3). Filter exts into counterpoised weighed beaker, using cotton pledget moistened with the  $CHCl_3$ -ether mixt. in stem of funnel. Evap. on  $H_2O$  bath and dry to const wt at  $120^\circ$ . Wt may be checked by tetraiodo method, 37.136.

**Aminopyrine—Official Final Action****37.055 Qualitative Tests (25)**

(a) Dissolve 0.01 g sample in 2 mL  $H_2O$  and add few drops of yellow  $HNO_3$  (contg  $HNO_2$ ). Purplish blue soln is produced.

(b) Dissolve 0.01 g sample in 2 mL  $H_2O$  and add 1 mL 10%  $FeCl_3$  soln. Purple to violet color develops, which becomes red on addn of  $H_2SO_4$  (1+9).

(c) Dissolve 0.1 g sample in 2 mL  $H_2O$  and add few drops of 5%  $AgNO_3$  soln. After few sec, purple to violet color is produced, and on standing, deposit of metallic Ag results (useful for detecting aminopyrine in antipyrine).

(d) Dissolve 0.1–0.2 g sample in 2 mL  $H_2O$ , add 1 or 2 drops 0.2%  $NaNO_2$  soln and few drops of  $H_2SO_4$  (1+9), and shake few sec. Purplish blue color develops and then gradually fades, leaving colorless soln. Excess  $NaNO_2$  destroys aminopyrine color. On addn of few more drops of  $NaNO_2$  soln and dil.  $H_2SO_4$ ,

★ Surplus method—see inside front cover.

yellowish green color remains after purple disappears if antipyrine is present. (Useful for detecting antipyrine in presence of aminopyrine.)

### 37.056 Quantitative Method (26)

(Caution: See 51.011, 51.040, and 51.056.)

Place 1 g powd sample in 100 mL vol. flask, add 60 mL 1*N* H<sub>2</sub>SO<sub>4</sub>, and shake several min to ensure complete soln of aminopyrine. Dil. to vol. with 1*N* H<sub>2</sub>SO<sub>4</sub>. Filter, if not clear, thru dry filter, rejecting first part of filtrate. Pipet 20 mL aliquot of soln or filtrate into separator; make distinctly alk. with either NH<sub>4</sub>OH or 5% NaOH; and ext with 20, 15, 10, 10, and 5 mL portions CHCl<sub>3</sub>. Combine CHCl<sub>3</sub> exts in second separator and wash with 2 mL H<sub>2</sub>O. Filter CHCl<sub>3</sub> soln into weighed beaker thru cotton pledget satd with CHCl<sub>3</sub>. Ext wash H<sub>2</sub>O with 5 mL CHCl<sub>3</sub> and add this to combined CHCl<sub>3</sub> exts. Evap. combined CHCl<sub>3</sub> exts just to dryness on H<sub>2</sub>O bath with aid of air current and dry residue 10 min at 100°. Cool in desiccator, and weigh as aminopyrine. Identify aminopyrine by its mp, 106.5–109°, and qual. tests, 37.055, or microchem. tests, Table 36.06.

## HYPNOTIC DRUGS

### Acetylcarbromal and Bromisovalum (27)

#### Official Final Action

### 37.057

#### Principle

Acetylcarbromal is eluted with heptane-CCl<sub>4</sub> and bromisovalum with H<sub>2</sub>O-satd CHCl<sub>3</sub> from diat. earth column. Eluates are dried; acetylcarbromal residue is dissolved in CCl<sub>4</sub> and bromisovalum residue in CHCl<sub>3</sub>. Concns are detd by IR spectrometry at 5.8 μm. Identification is made from residues in KBr disks.

### 37.058

#### Apparatus

(a) *Infrared spectrophotometer*.—Beckman IR-5, (current model Acculab 5), or equiv., with 1 mm liq. cells.

(b) *Chromatographic tube*.—See 37.002.

### 37.059

#### Reagents

(a) *Diatomaceous earth*.—See 36.002.

(b) *Reference std solns*.—1.00 mg/mL. Completely dissolve 50.0 mg acetylcarbromal (mp 109°) in CCl<sub>4</sub> in 50 mL vol. flask and dil. to vol. with CCl<sub>4</sub>. Completely dissolve 50.0 mg bromisovalum (mp 148–149°) in CHCl<sub>3</sub> in 50 mL vol. flask and dil. to vol. with CHCl<sub>3</sub>.

### 37.060

#### Column Chromatography

(Caution: See 51.011, 51.040, 51.049, and 51.056.)

Pack small wad of fine glass wool into bottom of tube. Thoro mix 4 g diat. earth with 5 mL HCl (2+1), transfer to tube, and tamp to uniform mass with tamping rod.

Det. av. wt/tablet and pulverize. Accurately weigh portion of powder contg 10–30 mg acetylcarbromal, and mix in beaker with 1 g diat. earth and 1 mL H<sub>2</sub>O. Transfer to tube, dry-rinse beaker with small portion diat. earth, and tamp to uniform mass. Wash beaker with few portions H<sub>2</sub>O-satd CCl<sub>4</sub>-heptane (1+1) and pour thru column. Elute acetylcarbromal with CCl<sub>4</sub>-heptane mixt., collecting 50 mL eluate in beaker. Immediately, without letting column go dry, elute bromisovalum with 100 mL H<sub>2</sub>O-satd CHCl<sub>3</sub>, collecting eluate in beaker. Evap. both eluates to complete dryness on steam bath with air current.

Dissolve acetylcarbromal residue with several portions of CCl<sub>4</sub> (dried with anhyd. Na<sub>2</sub>SO<sub>4</sub>) and dil. to concn of 1 mg/mL. Dissolve bromisovalum residue in several portions of CHCl<sub>3</sub>

(dried with anhyd. Na<sub>2</sub>SO<sub>4</sub>) and dil. to concn of 1 mg/mL. Using their resp. solvs as ref. solns, det. IR spectrum at 5–7 μm. For calcn, use *A* of max. at ca 5.8 μm, using baseline technic:

$$\% \text{ Compd} = (100 \times A \times C \times V) / (A' \times W),$$

where *A* and *A'* refer to sample and std solns, resp., *C* = concn of std soln (mg/mL), *V* = final vol. sample soln, and *W* = mg sample.

### 37.061

#### Identification

Evap. 1 mL each of std and sample soln, and prep. KBr disk from each of residues, using ca 200 mg KBr. Scan IR spectra for identification.

### Carbromal (28)—Official Final Action

### 37.062

#### Apparatus

See Fig. 37.01. Consists of 100 mL r-b flask with 24/40 ♂ inner joint; condenser with jacket ca 130 mm long; and absorption flask with 2 bulbs. Condenser is equipped with 12/30 and 24/40 ♂ inner joints. Small dropping funnel is fused to tube above jacket. Absorption flask has outer 12/30 ♂ joint. Small springs (not shown) are attached to hooks on joints to keep app. tightly connected during use.

FIG. 37.01—Bromine apparatus

### 37.063

#### Determination

Place sample calcd to contain 40–60 mg Br in oxidn flask and dissolve in 2 mL 10% NaOH soln and 8 mL H<sub>2</sub>O. Lubricate joints of app. with H<sub>3</sub>PO<sub>4</sub> and connect flask to condenser. Place ca 15 mL 1% N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>SO<sub>4</sub> soln and 5 mL 10% NaOH soln in absorption flask and connect to app. (Use <20 mL absorbing soln if app. has smaller absorption bulbs than indicated.)

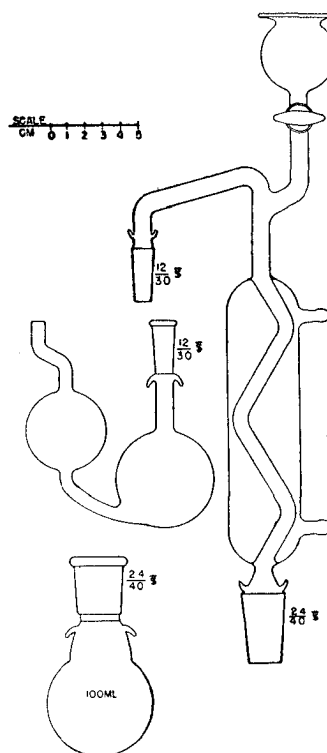

FIG. 37.01—Bromine apparatus

Add 5 mL  $\text{CrO}_3$  soln (1+1) thru addn tube, wash down with 2–3 mL  $\text{H}_2\text{O}$ , and then slowly add 10 mL  $\text{H}_2\text{SO}_4$ . If vigorous reaction begins, let it subside before heating flask; if reaction does not begin as acid is added, heat gently with small flame, but remove flame before reaction becomes too vigorous, otherwise reaction mixt. may foam up into condenser. When reaction subsides, heat mixt. to boiling. When foaming subsides, add 5 mL  $\text{H}_2\text{SO}_4$  thru dropping funnel, boil 10 min, add another 5 mL  $\text{H}_2\text{SO}_4$ , and boil again 10 min. Drain  $\text{H}_2\text{O}$  from condenser and boil reaction mixt. until 2–3 drops  $\text{H}_2\text{O}$  distil into absorber.

Disconnect absorption flask, wash contents into 500 mL I flask, and dil. to ca 100 mL with  $\text{H}_2\text{O}$ . Add ca 12 mL  $\text{H}_3\text{PO}_4$ , 5 mL 3%  $\text{KCN}$  soln, and 15 mL 3%  $\text{KMnO}_4$  soln, wetting sides of flask with each reagent as it is added. Stopper flasks and mix by gentle swirling, wetting entire inside surface. Let stand  $\geq 7$  min; then add ca 2 g solid  $\text{FeSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$ . Wash down sides of flask and mix. (Clear, nearly colorless soln should result.) If any  $\text{KMnO}_4$  or  $\text{MnO}_2$  remains, add more  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$  (2 g excess does no harm).

Add ca 2 g KI and immediately titr. liberated I with 0.05N  $\text{Na}_2\text{S}_2\text{O}_3$ , using starch indicator. (End point is disappearance of starch-I color; avoid over-titrn as color of soln remains light blue.) 1 mL 0.05N  $\text{Na}_2\text{S}_2\text{O}_3$  = 0.001998 g Br or 0.00593 g carbromal.

#### 37.064 Carbromal and Pentobarbital (28) Official Final Action

(Caution: See 51.011, 51.040, and 51.056.)

Transfer 0.5–0.7 g sample to separator, and add 15 mL  $\text{H}_2\text{O}$  and 0.5 mL 1N NaOH from pipet. Ext carbromal with at least five 25 mL portions  $\text{CHCl}_3$ , washing each portion in second separator contg 10 mL  $\text{H}_2\text{O}$  and 2 drops 0.1N NaOH. Filter  $\text{CHCl}_3$  thru cotton and transfer to tared flask or beaker. Test for complete extn. Evap.  $\text{CHCl}_3$  soln of carbromal nearly but not quite to dryness on steam bath in air current. Remove container and let stand in air to const wt.

Combine aq. solns and proceed as in 37.065, beginning "Acidify to litmus paper . . ." Wt pentobarbital  $\times 1.097$  = wt Na pentobarbital in portion taken for assay. Det. mp of dried exts. Carbromal melts at 116–119° and pentobarbital at 126–130°.

#### Barbiturates—Official Final Action

(See also 38.111–38.117 for barbital and phenobarbital and 39.113–39.116 for mannitol hexanitrate and phenobarbital.)

#### 37.065 Method I (29)

(Applicable in absence of stearic acid. Caution: See 51.011, 51.040, and 51.056.)

Accurately weigh 0.3–0.5 g sample into separator, add 10 mL  $\text{H}_2\text{O}$ , and shake well. Add 5 mL 0.5N NaOH and shake again. Acidify to litmus paper with HCl (1+3), added dropwise, and add ca 1 mL excess. Ext with successive 40, 30, 20, 20, and 10 mL portions  $\text{CHCl}_3$ . Test for complete extn by shaking with addnl 10 mL solv. and evapg in sep. beaker.

Combine solv. in second separator and wash with 2 mL  $\text{H}_2\text{O}$  acidified with 1 drop HCl. Filter solv. thru cotton pledget into small weighed beaker. Evap. on steam bath with aid of air current, heat 10 min at 80–90°, cool in desiccator, and weigh. Add 2 or 3 mL anhyd. ether and evap. solv. (Usually 2 treatments with 2 mL each of anhyd. ether are enough to remove last traces of  $\text{CHCl}_3$  and to produce cryst. residue.) Dry at 80–90°, cool, and weigh. Repeat treatment with anhyd. ether and evapn to const wt. Det. mp to check purity of residue.

#### 37.066 Method II (30)—Official Final Action

(Applicable in presence of stearic acid)

Dissolve residue obtained in 37.065 in 10 mL alcohol, add 20 mL satd  $\text{Ba}(\text{OH})_2$  soln, and stir well. Filter into separator, and wash residue and filter with two or three 10 mL portions of the  $\text{Ba}(\text{OH})_2$  soln. Acidify filtrate with HCl (1+3) and proceed as in 37.065, beginning "Ext with successive . . ."

#### 37.067 Microscopic Tests—Official Final Action

See 36.098–36.099, Tables 36:04 and 36:06, and 36.106–36.108.

#### ★ Amobarbital Sodium and Secobarbital ★ Sodium (31)—Official Final Action

#### 37.068

#### Reagents

(a) Sodium secobarbital std.—Assay by 37.065.

(b) Phosphate buffer soln.—pH 6.85–6.90. Dissolve 6.80 g  $\text{KH}_2\text{PO}_4$  in ca 500 mL  $\text{H}_2\text{O}$  in 1 L vol. flask. Add 23.6 mL 1.00N NaOH soln and dil. to vol. with  $\text{H}_2\text{O}$ .

#### 37.069

#### Preparation of Standard Curve

Accurately weigh ca 100 mg Na secobarbital, transfer to 25 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix well. Calc. equiv. barbituric acid/mL std soln as follows:

mg Barbituric acid/mL = (mg Na secobarbital/25)  
 $\times$  (% Na secobarbital (from assay)/100)  $\times$  (128.09/260.27).

Pipet 0.5, 1.0, and 2.0 mL aliquots into 50 mL vol. flasks, dil. to vol. with buffer soln, and mix. Det. A of each soln at 237 nm against buffer soln. Plot A against mg barbituric acid.

Include 1 or 2 stds with each set of detns.

#### 37.070

#### Determination of Total Barbiturates

Accurately weigh sample contg ca 400 mg total Na amobarbital and Na secobarbital, transfer to 100 mL vol. flask, and dil. to vol. with  $\text{H}_2\text{O}$ . Mix, and let stand 10 min with occasional shaking. Filter thru quant. paper retentive enough to produce clear soln, discarding first 10–15 mL filtrate. Pipet 2 mL filtrate into 50 mL vol. flask, dil. to vol. with buffer soln, and mix well. Det. A at 237 nm against buffer soln. Det. total barbituric acid in aliquot by ref. to std curve and calc. to mg total barbituric acid in sample.

#### 37.071

#### Determination of Sodium Secobarbital

Pipet 50 mL filtrate into I flask and add 10.0 mL 0.1N KBr- $\text{KBrO}_3$ , 50.020. Add 5 mL HCl, stopper at once, and let stand 5 min, shaking occasionally. Add 10 mL 10% KI soln, stopper, and shake. Rinse stopper and neck of flask with  $\text{H}_2\text{O}$ , add starch indicator, and titr. liberated I with 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , 50.037, using 10 mL buret. 1 mL 0.1N KBr- $\text{KBrO}_3$  consumed = 13.01 mg Na secobarbital. Calc. to mg Na secobarbital in sample.

#### 37.072

#### Determination of Sodium Amobarbital (by Difference)

mg Na amobarbital in sample = [mg total barbituric acid  
– (mg Na secobarbital  $\times 0.492$ )]  $\times 1.94$ .

#### Phenobarbital and Aminophylline (32) Official Final Action

#### 37.073

#### Reagents

(a) Dilute ammonium hydroxide soln.—0.1%  $\text{NH}_3$ . Dil. 4 mL  $\text{NH}_4\text{OH}$  to 1 L with  $\text{H}_2\text{O}$ .

★ Surplus method—see inside front cover.

(b) *Phenobarbital std soln.*—10 µg/mL. Dissolve 100.0 mg phenobarbital in the dil.  $\text{NH}_4\text{OH}$  soln in 500 mL vol. flask, dil. to vol. with the dil.  $\text{NH}_4\text{OH}$ , and mix. Transfer 5 mL aliquot to 100 mL vol. flask, dil. to vol. with the dil.  $\text{NH}_4\text{OH}$ , and mix.

(c) *Theophylline std soln.*—10 µg/mL. Dissolve 100.0 mg theophylline in HCl (1+18) in 500 mL vol. flask. Dil. to vol. with HCl (1+18) and mix. Transfer 5 mL aliquot to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.

### 37.074 Separation of Aminophylline and Phenobarbital

Transfer weighed portion of powd sample contg ca 15 mg phenobarbital to separator contg 25 mL HCl (1+1). Add 60 mL ether, shake, and let stand to clear. Pass aq. soln successively thru 2 other separators, each contg 50 mL ether, shake, and let stand to clear. Transfer ether-washed aq. soln to 500 mL vol. flask. Wash the 3 ether solns successively with three 10 mL portions HCl (1+1) and one 10 mL portion  $\text{H}_2\text{O}$ , and add these washes to the vol. flask. Reserve for detn of theophylline.

### 37.075 Determination of Phenobarbital

(Caution: See 51.011, 51.039, and 51.054.)

Combine ether solns and evap. to dryness. Dissolve residue in ca 100 mL of the dil.  $\text{NH}_4\text{OH}$  and transfer to 200 mL vol. flask. Dil. to vol. with the dil.  $\text{NH}_4\text{OH}$  and mix. Filter, if necessary, transfer 10 mL aliquot to 100 mL vol. flask, dil. to vol. with the dil.  $\text{NH}_4\text{OH}$ , and mix. Det.  $A_p$  at max., ca 240.5 nm, against dil.  $\text{NH}_4\text{OH}$ . Read this soln same day it is prepd.

Det.  $A_p$  of std phenobarbital soln, (b), at same wavelength, using the dil.  $\text{NH}_4\text{OH}$  as blank. Calc.  $a_p = A_p/cb$ , where  $c = 0.01$  g/L, and  $b =$  cell length in cm. Phenobarbital (g/L sample soln) =  $A_p/a_p$ .

If stearates are present, proceed as above, dissolving residue in ca 100 mL of the dil.  $\text{NH}_4\text{OH}$  and dilg to ca 190 mL with the dil.  $\text{NH}_4\text{OH}$ . Acidify with HCl, testing with litmus paper. Dil. to vol. with  $\text{H}_2\text{O}$ , mix, and filter. Transfer 10 mL aliquot to 100 mL vol. flask, add 1 drop  $\text{NH}_4\text{OH}$  (1+1), dil. to vol. with the dil.  $\text{NH}_4\text{OH}$ , and det.  $A_p$  at 240.5 nm.

### 37.076 Determination of Theophylline

Dil. aq. soln in vol. flask to vol. with  $\text{H}_2\text{O}$  and mix. Transfer aliquot contg 0.5–1.0 mg theophylline to 100 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Det.  $A_T$  at 271 nm against blank soln contg same vol. HCl. Det.  $A_T'$  of std theophylline soln, (c), and calc.  $a_T$  as in 37.075. Theophylline (g/L sample soln) =  $A_T/a_T$ . Aminophylline,  $\text{C}_{16}\text{H}_{24}\text{N}_{10}\text{O}_4 \cdot 2\text{H}_2\text{O} = 1.267 \times$  theophylline.

### Phenobarbital and Diphenylhydantoin (33) Official Final Action

#### 37.077

#### Reagents

(a) *Water-saturated soln of 15% n-amyl alcohol in  $\text{CHCl}_3$ .*—Sat. 500 mL 15% n-amyl alcohol in  $\text{CHCl}_3$  with 25 mL  $\text{H}_2\text{O}$  and let stand 30 min. Det. suitability of reagent by passing 80 mL thru prepd column followed by 25 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ , evapg to dryness on steam bath with air current, dilg to 25.0 mL with alcohol, and reading  $A$  in 1 cm cell on recording spectrophtr from 320 to 250 nm. If  $(A_{258} - A_{263}) \leq 0.190$ , make blank correction. Higher  $\Delta A$  indicates better grade reagent must be used.

(b) *Acetic acid-chloroform soln.*—1% HOAc in  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ .

### 37.078 Preparation of Standards

(a) *Phenobarbital std soln.*—Weigh and transfer 20 mg phenobarbital, USP, to 50 mL vol. flask; dissolve and dil. to vol. with alcohol. Pipet 10 mL into 125 mL g-s erlenmeyer and evap. to

dryness on steam bath with air current (4 mg/100 mL 0.1N NaOH has  $A$  of ca 1.30 at max., ca 253 nm, in 1 cm cell).

(b) *5,5-Diphenylhydantoin std soln.*—Weigh and transfer 90 mg diphenylhydantoin (Eastman), to 50 mL vol. flask; dissolve and dil. to vol. with alcohol. Pipet 10 mL into 125 mL g-s erlenmeyer and evap. to dryness on steam bath with air current (18 mg/25 mL alcohol has  $A$  of ca 1.90 at max., ca 258 nm, in 1 cm cell).

### 37.079

#### Preparation of Sample

Accurately weigh powd sample contg ca 90 mg diphenylhydantoin and transfer to 50 mL vol. flask. Add 1.5 mL alcohol, 0.1 mL HOAc, and ca 25 mL reagent, 37.077(a). Heat on steam bath with swirling until  $\text{CHCl}_3$  boils. Remove from heat and swirl 5 min. Heat to boiling as before, remove, and let stand 15 min with frequent agitation. Let cool and dil. to vol. with reagent (a). (Diphenylhydantoin dissolves with difficulty. Turbidity of soln may persist because of insol. excipients.)

### 37.080

#### Preparation of Column

Use glass tube 25 mm diam.  $\times$  15–30 cm long, with stem plugged with glass wool, and glass tamping rod weighing ca 32 g and having 20–22 mm ram head.

(a) *Column packing.*—(1) *Bottom layer.*—Mix 2 g diat. earth, 36.002, and 1 mL 12%  $\text{BaCl}_2$  soln. (2) *Top layer.*—Mix 4 g diat. earth, 36.002, and 3 mL satd  $\text{Na}_3\text{PO}_4$  soln.

(b) *Packing technic.*—Column must be packed exactly as follows: Transfer sep. bottom and top packing layers to tube in 1–2 g portions and tamp 10–15 times with tamping rod after addn of each portion by dropping rod from 2.5 cm above packing surface.

Place glass wool pad over diat.earth mixt. and pass 25 mL reagent (a) thru column at 5–10 mL/min, discarding eluate.

### 37.081

#### Determination

(Caution: See 51.011, 51.022, 51.040, and 51.056.)

Place 125 mL g-s erlenmeyer under column and pipet 10 mL sample soln directly over glass wool pad. Let drain into column, and wash column with three 10 mL portions reagent (a), letting each drain into column. Add addnl 40 mL reagent (a). Pass 25 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$  thru column, wash stem with  $\text{CHCl}_3$ , and evap. eluate to dryness on steam bath with air current. (Odor of *n*-amyl alcohol must be absent.) Residue is diphenylhydantoin.

Place 125 mL g-s erlenmeyer under column and add to column 5 mL HOAc in  $\text{CHCl}_3$  (1+4). Let drain into column. Add 20 mL reagent, 37.077(b), let drain into column, and add 70 mL more. Wash stem with  $\text{CHCl}_3$  and evap. eluate to dryness on steam bath with air current. Residue is phenobarbital.

Add 25 mL alcohol by pipet to both sample and std diphenylhydantoin residues. Stopper and warm with swirling. Let stand, swirling occasionally, until solid matter is completely dissolved. Det  $A$  of sample and std solns against reagent, 37.077(a), on recording spectrophtr from 320 to 250 nm in 1 cm cell.

mg Diphenylhydantoin/capsule

$$= C \times (K/W) \times (A_{258} - A_{263}) / (A'_{258} - A'_{263}),$$

where  $A_{258}$  and  $A_{263}$  = max. and min.  $A$  of sample soln at ca 258 and 263 nm, resp.;  $A'_{258}$  and  $A'_{263}$  = max. and min.  $A$  of std soln at 258 and 263 nm, resp.;  $C$  = mg std diphenylhydantoin;  $K$  = av. capsule content wt (mg); and  $W$  = mg sample. Diphenylhydantoin  $\times 1.087$  = Na diphenylhydantoin.

Add 100 mL 0.1N NaOH by pipet to both sample and std phenobarbital residues. Stopper and shake vigorously 2 min.

Immediately read *A* of solns on recording spectrophtr from 350 to 230 nm in 1 cm cell.

$$\text{mg Phenobarbital/capsule} = C \times (K/W) \times (A_{253}/A'_{253}),$$

where  $A_{253}$  and  $A'_{253}$  = *A* of sample and std solns, resp., at max., ca 253 nm; *C* = mg std phenobarbital; *K* = av. capsule content wt (mg); *W* = mg sample.

#### Phenobarbital and Theobromine (34)—Official Final Action

##### 37.082

##### Reagents

(a) *Theobromine std soln.*—1.00 mg/100 mL. Dissolve 100 mg theobromine in  $\text{H}_2\text{SO}_4$  (1+4), and dil. to 100 mL with this acid. Transfer 5.0 mL aliquot to 500 mL vol. flask, add 200 mL 5% NaOH soln, and cool to room temp. Dil. to vol. with  $\text{H}_2\text{O}$  and mix thoroly.

(b) *Phenobarbital std soln.*—1.50 mg/100 mL. Dissolve 75.0 mg phenobarbital in  $\text{CHCl}_3$  and dil. to 100 mL with  $\text{CHCl}_3$ . Dil. 10 mL aliquot to 50 mL with  $\text{CHCl}_3$ . Transfer 10 mL aliquot of latter soln to 100 mL vol. flask, dil. to vol. with  $\text{CHCl}_3$ , and mix.

##### 37.083

#### Separation of Theobromine and Phenobarbital

(Caution: See 51.011, 51.039, and 51.054.)

Transfer portion of well mixed sample contg  $\geq 15$  mg phenobarbital to 125 mL separator, add 15 mL 5% NaOH soln, and ext with three 30 mL portions  $\text{CHCl}_3$ . Wash each  $\text{CHCl}_3$  ext with 10 mL 5% NaOH soln in second separator. Discard  $\text{CHCl}_3$ .

Add 30 mL  $\text{H}_2\text{SO}_4$  (1+4) to alk. mixt. in first separator, cool thoroly, and shake with 50 mL ether. Transfer aq. layer contg dissolved theobromine to second separator, cool, and shake with 40 mL ether. Remove lower phase to third separator and wash with another 40 mL portion ether. Repeat extn thru the 3 separators, using two 40 mL portions  $\text{H}_2\text{SO}_4$  (1+4) and two 20 mL portions  $\text{H}_2\text{O}$ . Collect aq. exts in 250 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Reserve for theobromine detn.

Filter ether solns thru cotton pledget into beaker, washing the 3 separators and filter successively with three 5 mL portions ether. Evap. carefully to dryness, and dissolve residue in  $\text{CHCl}_3$ .

##### 37.084

#### Spectrophotometric Determinations

(a) *Theobromine.*—Pipet aliquot contg 4–8 mg theobromine into 500 mL vol. flask, add 200 mL 5% NaOH soln, and cool to room temp. Dil. to vol. with  $\text{H}_2\text{O}$  and mix. Det. *A* at 274 nm of this soln and of std theobromine soln, (a), *A'*, relative to soln prep'd by dilg 10 mL 5% NaOH soln to 25 mL. Calc. theobromine content of sample.

$$\text{mg Theobromine in aliquot} = 5.0 A/A'.$$

(b) *Phenobarbital.*—Transfer  $\text{CHCl}_3$  soln to vol. flask and dil. with  $\text{CHCl}_3$  to obtain soln contg 20–40 mg phenobarbital/100 mL. Place 5.0 mL in 100 mL vol. flask, dil. to vol. with  $\text{CHCl}_3$ , and mix. Transfer 20 mL aliquot of latter soln to separator contg 25 mL  $\text{NH}_4\text{OH}$  (1+24). Similarly treat 20 mL aliquot std phenobarbital soln, (b), and 20 mL portion  $\text{CHCl}_3$  as blank. Shake vigorously  $\geq 1$  min, sep., and discard  $\text{CHCl}_3$ . Let aq. ext stand 30 min. Det. *A* at 241 nm of clear aq. solns of sample, and of std, *A'*, relative to blank, using same cell for std and sample. Calc. phenobarbital content of sample.

$$\text{mg Phenobarbital in final aliquot} = 0.30A/A'.$$

In presence of salicylates, proceed as in (c):

(c) *Phenobarbital in presence of salicylates.*—Prep. chromatgc column as in 37.051, and adjust flow to 2–4 mL/min.

When  $\text{CHCl}_3$  just stops flowing from tube, pipet 5 mL original  $\text{CHCl}_3$  soln, (b), (equiv. to 1–2 mg phenobarbital) into tube, and collect eluate in 100 mL vol. flask. As level of  $\text{CHCl}_3$  soln reaches top of column, add ca 5 mL  $\text{CHCl}_3$ , and repeat with second  $\text{CHCl}_3$

wash. Add enough  $\text{CHCl}_3$  to keep column of solv. 2–5 cm high, and collect ca 95 mL eluate. Wash outside surface of stem with stream of  $\text{CHCl}_3$  and collect washings in vol. flask. Dil. to vol. with  $\text{CHCl}_3$  and mix thoroly. Det. phenobarbital in eluates as in (b), beginning "Transfer 20 mL aliquot of latter soln . . ."

#### Sodium Butabarbital (35)—Official Final Action

##### 37.085

##### Reagents

(a) *Sodium carbonate soln.*—1*M*. Dissolve 10.6 g  $\text{Na}_2\text{CO}_3$  and dil. to 100 mL with  $\text{H}_2\text{O}$ .

(b) *Mixed solvent.*—Isooctane-ether (4+1). Wash mixed solv. with equal vol.  $\text{H}_2\text{O}$ .

(c) *Ether.*— $\text{H}_2\text{O}$ -satd. Use thruout.

(d) *Dilute ammonium hydroxide.*—Dil. 30 mL  $\text{NH}_4\text{OH}$  to 1 L with  $\text{H}_2\text{O}$ .

(e) *Diatomaceous earth.*—See 36.002.

(f) *Dimethylsulfoxide (DMSO).*—Spectral grade (Fisher Scientific Co. D-136; M/CB Manufacturing Chemists MX 1457).

(g) *Butabarbital std solns.*—(1) *Stock soln.*—0.1 mg/mL. Dissolve 20 mg USP Ref. Std in  $\leq 1$  mL MeOH and dil. to 200 mL with dil.  $\text{NH}_4\text{OH}$ . (2) *Working soln.*—0.01 mg/mL. Dil. 10 mL stock soln to 100 mL with dil.  $\text{NH}_4\text{OH}$ .

##### 37.086

#### Preparation of Sample

Det. av. wt/tablet and pulverize. Transfer accurately weighed portion contg ca 20 mg butabarbital to 100 mL beaker. Add 1 mL *DMSO* and 2 drops HCl, and swirl to dissolve active ingredient. Add 1 mL  $\text{H}_2\text{O}$  and 3 g diat. earth, and mix thoroly until uniform.

##### 37.087

#### Preparation of Column

Place small glass wool plug at base of 250  $\times$  25 mm chromatgc tube. Transfer uniform mixt. of 4 g diat. earth and 3 mL  $\text{Na}_2\text{CO}_3$  soln to tube and tamp to uniform mass. Transfer sample prep'n to column, drywash beaker with 1 g diat. earth, transfer wash to column, and tamp.

##### 37.088

#### Determination

Pass 75 mL mixed solv. thru column and discard. Elute butabarbital with 100 mL ether, collecting eluate in 250 mL separator. Rinse tip of column with ether. Ext eluate with three 50 mL portions dil.  $\text{NH}_4\text{OH}$ , collect extns in 200 mL vol. flask, and adjust to vol. with dil.  $\text{NH}_4\text{OH}$ . Dil. 10.0 mL of this soln to 100.0 mL with dil.  $\text{NH}_4\text{OH}$ . Read *A* of sample and std solns at max. ca 239 nm against dil.  $\text{NH}_4\text{OH}$  as ref. and calc. Na butabarbital.

#### Sodium Diphenylhydantoin in Capsules (36) Official Final Action

##### 37.089

##### Reagents

(a) *Sodium carbonate.*—0.5*M*. Dissolve 5.3 g  $\text{Na}_2\text{CO}_3$  and dil. to 100 mL.

(b) *Mixed solvent.*—Isooctane- $\text{CHCl}_3$  (7+3). Wash mixed solv. with equal vol.  $\text{H}_2\text{O}$ .

(c) *Chloroform.*— $\text{H}_2\text{O}$ -satd. (Caution: See 51.056.)

(d) *Acid-alcohol.*—Dil. 1 mL HCl (1+99) with 50 mL alcohol.

(e) *Diatomaceous earth.*—See 36.002.

(f) *Diphenylhydantoin std soln.*—0.25 mg/mL. Dissolve 25 mg USP Ref. Std in 100 mL acid-alcohol.

##### 37.090

#### Preparation of Sample

Remove, as completely as possible, contents of capsules and weigh. Det. av. net contents. Mix, and transfer accurately

weighed portion contg ca 100 mg Na diphenylhydantoin to 25 mL vol. flask. Add 2 mL DMSO, 37.085(f), and swirl mixt. ca 3 min. Add 4 drops HCl, swirl to mix, and immediately but cautiously add 0.5M Na<sub>2</sub>CO<sub>3</sub> to vol. Mix, and filter thru rapid paper.

**37.091****Preparation of Column**

Place small glass wool plug at base of 250 × 25 mm chromatg tube. Mix 3 g diat. earth and 2 mL 0.5M Na<sub>2</sub>CO<sub>3</sub>, and transfer to tube; tamp. Mix 3 g diat. earth and 2.0 mL prepd sample soln, and transfer to column. Dry-wash beaker with ca 1 g diat. earth, and transfer wash to column. Place pad of glass wool on top of column.

**37.092****Determination**

Pass 75 mL mixed solv. thru column, and discard. Elute diphenylhydantoin with 75 mL CHCl<sub>3</sub>, collecting eluate in 125 mL g-s erlenmeyer. Rinse tip of column with CHCl<sub>3</sub>. Evap. solv. to dryness on steam bath under air current. Dissolve residue in 25.0 mL acid-alcohol. Det. A of sample and std solns at max., ca 258 nm, against acid-alcohol as ref. Calc. Na diphenylhydantoin content. Diphenylhydantoin × 1.087 = Na diphenylhydantoin.

**Chloral Hydrate (37)—Official Final Action****37.093****Principle**

Quinaldine ethyl iodide reacts with chloral hydrate to produce stable blue cyanine dye with A max. at ca 605 nm. Other polychlorinated compds do not interfere.

**37.094****Reagents**

(a) *Quinaldine ethyl iodide soln.*—1.5%. Dissolve 1.5 g quinaldine ethyl iodide in H<sub>2</sub>O and dil. to 100 mL. Filter if necessary.

(b) *2-Aminoethanol soln.*—0.1N. Dissolve 6.1 g 2-aminoethanol in H<sub>2</sub>O and dil. to 1 L.

(c) *Chloral hydrate std soln.*—100 µg/mL. Dissolve 0.2500 g chloral hydrate USP in H<sub>2</sub>O and dil. to 250 mL. Dil. 10 mL aliquot to 100 mL with H<sub>2</sub>O.

**37.095****Apparatus**

*Recording spectrophotometer.*—400–800 nm range with matched 1 cm cells.

**37.096****Preparation of Sample**

(a) *Capsules.*—Place counted number of capsules contg ca 2.5 g chloral hydrate in g-s 250 mL flask, add 25 mL H<sub>2</sub>O, stopper, and heat on steam bath with frequent swirling until dissolved. Cool, and transfer quant. to 250 mL vol. flask with H<sub>2</sub>O. Dil. to vol., mix, and dil. stepwise to ca 100 µg/mL with H<sub>2</sub>O.

(b) *Solns.*—Prep. soln contg ca 100 µg chloral hydrate/mL by stepwise diln with H<sub>2</sub>O.

**37.097****Determination**

Pipet 10 mL sample soln contg ca 1 mg chloral hydrate into 100 mL vol. flask and pipet 10 mL std chloral hydrate soln into second 100 mL vol. flask. Pipet 10 mL H<sub>2</sub>O into third 100 mL vol. flask as blank. To each flask add 10 mL quinaldine ethyl iodide soln and 60 mL isopropanol, and mix. Add 5 mL 0.1N 2-aminoethanol and dil. to vol. with H<sub>2</sub>O. Place in H<sub>2</sub>O bath 1 hr at 60°. Cool, and record spectra of sample and std from 400 to 800 nm against blank. Do not exceed 120 nm/min near max.

Det A max. at ca 605 nm, using baseline technic with ca 430 and ca 770 nm as base.

$$\begin{aligned} &\text{mg Chloral hydrate in sample aliquot} \\ &= (\text{net A of sample soln} / \text{net A of std soln}) \\ &\quad \times \text{mg chloral hydrate in 10 mL std soln.} \end{aligned}$$

**37.098 ★ (2-Isopropyl-4-Pentenyl) Urea ★ (Sedormid®) (38)—Official Final Action**

Direct CHCl<sub>3</sub> extn. See 32.237, 10th ed.

**37.099 ★ Sulfonmethane (Sulfonal®) or ★ Sulfonethylmethane (Trional®) (39) Official Final Action**

Direct ether extn. See 32.238, 10th ed. (Caution: See 51.011, 51.039, and 51.054.)

**Ethchlorvynol (1-Chloro-3-ethyl-1-penten-4-yn-3-ol) (40) Official Final Action****37.100****Reagents**

(a) *Ethchlorvynol.*—(Caution: See 51.011 and 51.015.) Purify by vac. distn (62° at ca 10 mm) or assay by titrn as follows: Transfer ca 110 mg ethchlorvynol, accurately weighed, to 250 mL erlenmeyer contg 50 mL 2.5% AgNO<sub>3</sub> soln in 70% alcohol. Immediately titr. with 0.05N NaOH, using 8–10 drops Me red-methylene blue, (e). Perform blank detn and make any necessary correction. 1 mL 0.05N NaOH = 7.230 mg ethchlorvynol. (Caution: Protect pure ethchlorvynol from excessive exposure to light and air.) Store at <10° in glass containers with polyethylene or Teflon stopper liners.

(b) *Ethchlorvynol stock soln.*—10 mg/mL. Accurately weigh ca 0.5 g ethchlorvynol and dissolve in 5 mL alcohol. Transfer quant. to 50 mL vol. flask with 10 mL alcohol. Dil. to vol. with H<sub>2</sub>O.

(c) *Internal std soln.*—2.0%. Dissolve 2.0 g 1,3-dichloro-2-propanol in 10 mL alcohol and dil. to 100 mL with H<sub>2</sub>O.

(d) *Dichlorodimethylsilane soln.*—Dissolve 5 mL dichlorodimethylsilane in 100 mL toluene. (Caution: Dichlorodimethylsilane causes severe burns. Vapor is harmful. Avoid contact with skin, eyes, or clothing. Use effective fume removal device. See also 51.040.)

(e) *Methyl red-methylene blue mixed indicator.*—Dissolve 0.3 g Me red in 60 mL alcohol and dil. to 100 mL with H<sub>2</sub>O. Dissolve 0.2 g methylene blue in 100 mL 50% alcohol and add to Me red soln.

**37.101****Apparatus**

*Gas chromatograph.*—With 1.2 m (4') × 4 mm glass column, packed with Carbowax 20M on 100–120 mesh Gas-Chrom Q, and H flame ionization detector. *Operating conditions:* temps (°)—column 115, detector 190, injection port 200; flow rates (mL/min)—N 50, H 92, air ca 500. Adjust column temp. to elute ethchlorvynol in 12–15 min (relative retention time of internal std is ca 0.8). Adjust H and air flow rates to give stable flame and good sensitivity. Adjust electrometer sensitivity so that 12 µg ethchlorvynol gives 50–70% deflection.

**37.102****Preparation of GLC Column**

Carefully wash inside of column and small amt of fine glass wool with dichlorodimethylsilane soln, rinse with alcohol, and dry thoroly. Dissolve 5.0 g Carbowax 20M in 100 mL CHCl<sub>3</sub>. Add Carbowax soln to 10.0 g 100–120 mesh Gas-Chrom Q in 250 mL

★ Surplus method—see inside front cover.

filter flask fitted with trap and stopper. Slowly apply vac. and maintain 5 min. Swirl slurry rapidly and transfer in small portions to buchner fitted with 9 cm Whatman No. 4 paper. Maintain vac. 5 min after last portion is added; then air dry coated support 1 hr by spreading on smooth surface. Oven dry addnl hr at 100°.

Carefully plug column exit with small pad of glass wool. Apply vac. to exit end and slowly add coated support thru inlet, tapping very gently to pack firmly. Pack to within 1 cm of area heated by injection port. Plug with glass wool and condition overnight at 220° with slow N stream.

**37.103****Preparation of Sample**

(a) *Capsules (200–500 mg)*.—Place counted number of capsules contg ca 2.5 g ethchlorvynol in 250 mL vol. flask; add 75 mL H<sub>2</sub>O and 30 mL alcohol, stopper, and heat on steam bath with frequent swirling until dissolved. Cool and dil. to vol. with H<sub>2</sub>O.

(b) *Capsules (100 mg)*.—Place 10 capsules in 100 mL vol. flask, add 50 mL H<sub>2</sub>O and 15 mL alcohol, stopper, and heat on steam bath with frequent swirling until dissolved. Cool and dil. to vol. with H<sub>2</sub>O.

(c) *Solutions*.—Prep. soln contg ca 10 mg ethchlorvynol/mL by stepwise diln with 20% alcohol.

**37.104****Determination**

Pipet 10 mL sample soln contg ca 100 mg ethchlorvynol into 50 mL vol. flask; pipet 10 mL ethchlorvynol stock soln into second 50 mL vol. flask. Pipet 10 mL internal std soln into each flask and dil. to vol. with H<sub>2</sub>O.

Rinse 10  $\mu$ L syringe with 50% alcohol and draw up 1  $\mu$ L 50% alcohol. Draw in 1  $\mu$ L air followed by 6  $\mu$ L sample. Draw in 1  $\mu$ L air and note sample vol. Insert needle thru septum of gas chromatograph, quickly depress plunger, and retract syringe needle. Inject 6  $\mu$ L of each soln. Run std before and after sample. Calc. amt of ethchlorvynol in 10 mL sample aliquot as follows:

$$C = C' \times (X/X') \times (I'/I),$$

where  $C$  and  $C'$  = mg ethchlorvynol in 10 mL sample aliquot and std stock soln, resp.;  $X$  = area ethchlorvynol peak in sample chromatogram;  $X'$  = av. area ethchlorvynol peak in std chromatograms;  $I$  = area internal std peak in sample chromatogram; and  $I'$  = av. area internal std peak in std chromatograms.

**Paraldehyde (41)—Official Final Action****37.105****Reagents**

(a) *Paraldehyde std.*—USP. Redistil twice and collect only fraction distg 120.5–123°. Store in amber g-s bottle. (Caution: Paraldehyde is toxic. Use effective fume removal device.)

(b) *Paraldehyde std solns.*—(1) *Stock soln.*—0.05 mL/mL. Pipet 5 mL std paraldehyde into 100 mL vol. flask, add 8.0 mL internal std, and dil. to vol. with acetone. (2) *Working std soln.*—0.005 mL/mL. Pipet 5 mL stock soln into 50 mL vol. flask and dil. to vol. with acetone.

(c) *Isoamyl alcohol.*—(M/CB Manufacturing Chemists). Check purity by injecting 5  $\mu$ L into gas chromatograph. If any interfering peaks are present, redistil. (Caution: See 51.011.)

(d) *Internal std.*—Dil. isoamyl alcohol, (c), with equal vol. acetone.

**37.106****Apparatus**

(a) *Gas chromatographic column.*—2% cyclohexane dimethanol succinate (HIEFF-8BP) plus 20% Carbowax 20M on 80–100 mesh Diatoport S (Hewlett-Packard Co., Avondale, PA 19311) or Chromosorb W (HP). Prep. as follows: Weigh 500 mg

HIEFF-8BP plus 5.0 g Carbowax 20M into 500 mL Morton flask. Add 200 mL CHCl<sub>3</sub> and, if necessary, heat on steam bath with swirling to dissolve liq. phase. Add 20 g 80–100 mesh Diatoport S (or Chromosorb W (HP)) and evap. CHCl<sub>3</sub> under reduced pressure on rotating evaporator. Remove last traces CHCl<sub>3</sub> in 100° oven. Pack 1.8 m (6')  $\times$  4 mm id glass column and condition column 16 hr at 190° with N flow of 60 mL/min before use.

(b) *Gas chromatograph.*—Packard Model 7800 (replaced by 5700) with flame ionization detector and Hewlett-Packard Model 3370A (replaced by 3380) electronic integrator, or equivs. GLC conditions: temps (°)—column 110, injection port 125, detector 125; flow rates (mL/min)—N carrier gas 60, air 600, H 60; sensitivity  $1 \times 10^{-8}$  amp; and chart speed 26"/hr.

**37.107****Preparation of Sample**

Pipet amt elixir contg 2.5 mL paraldehyde into 50 mL vol. flask. Add 4.0 mL internal std and dil. to vol. with acetone. Pipet 5 mL this soln into 50 mL vol. flask and dil. to vol. with acetone.

**37.108****Determination**

Inject ca 4  $\mu$ L std and sample solns into gas chromatograph operated as in 37.106(b). Make  $\geq 3$  injections of sample and std solns and take av.

Calc. amt paraldehyde in sample as follows:

$$\% \text{ Paraldehyde} = (R_x/R_s) \times C \times DF,$$

where  $R_x$  = ratio of sample to internal std peak area in sample soln,  $R_s$  = ratio of std to internal std peak area in std soln,  $C$  = concn of std (% v/v), and  $DF$  = sample diln factor.

Since GLC peaks for paraldehyde are narrow, symmetrical, and well defined, peak hts may be used in place of peak area.

**Phenaglycodol (42)—Official Final Action****37.109****Apparatus**

*Recording infrared spectrophotometer.*—With two 1.0 mm liq. cells with NaCl windows (preferably matched) and KBr disk holder.

**37.110****Reagents**

(a) *Phenaglycodol std.*—Available from Eli Lilly & Co., or equiv.

(b) *Carbon disulfide.*—Spectral grade.

(c) *Cotton.*—Wash thoroly with CHCl<sub>3</sub> and dry.

**37.111****Determination**

(Caution: See 51.011, 51.040, and 51.056.)

Det. av. wt/tablet or capsule, pulverize, and sieve to obtain uniform sample. Accurately weigh sample contg ca 200 mg phenaglycodol and transfer to 125 mL separator with 50 mL CHCl<sub>3</sub>. Add 15 mL 0.5N NaOH, shake 1 min, and filter sepd CHCl<sub>3</sub> layer thru cotton into 150 mL beaker. Ext alk. soln with two addnl 25 mL portions CHCl<sub>3</sub>, filtering each sepd CHCl<sub>3</sub> layer into beaker. Evap. combined exts just to dryness, using gentle current of air, at temp.  $< 50^\circ$ . Dissolve residue in CS<sub>2</sub>, transfer quant. to 50 mL vol. flask, and dil. to vol. with CS<sub>2</sub>.

Accurately weigh ca 200 mg std phenaglycodol, transfer to 125 mL separator with 50 mL CHCl<sub>3</sub>, and ext as above.

Det. baseline  $A$  of sample and std solns against CS<sub>2</sub> at ca 9.85  $\mu$ m. Draw baseline between minima at ca 9.75  $\mu$ m and ca 10.0  $\mu$ m. Calc. phenaglycodol content of sample.

Prep. KBr disk by grinding 2 mg residue and 200 mg spectroscopic grade KBr in Mullite mortar and press in die with hydraulic press. Record spectrum at 2–15  $\mu$ m and compare with spectrum of extd std residue to det. identity of sample.

## PHENOLIC DRUGS

**p-Aminosalicylic Acid (PAS) and Isonicotinylhydrazine (INH) (43)—Official Final Action**

37.112

**Reagents**

- (a) *Benzaldehyde*.—USP or reagent grade.  
 (b) *Concentrated phosphate buffer*.—pH 7. Dissolve 34 g anhyd.  $\text{KH}_2\text{PO}_4$  in 136 mL 1*N* NaOH and dil. to 1 L with  $\text{H}_2\text{O}$ .

37.113

**Extraction of Tablets**

(a) Accurately weigh sample of powd tablets contg 35–40 mg INH and transfer to 150 mL beaker. Stir with 20 mL  $\text{H}_2\text{O}$ , add 1.5 g  $\text{NaHCO}_3$ , and continue stirring until effervescence stops. Filter with vac. thru medium porosity fritted glass filter (3.5 cm diam. is convenient) precoated with ca 3 mm layer of diat. earth, 36.002. Rinse beaker thoroughly with 5 mL  $\text{H}_2\text{O}$ , break vac., transfer rinsings to funnel, washing down inside wall, and reapply vac. Repeat washing of beaker and funnel with 3 addnl 5 mL portions  $\text{H}_2\text{O}$ . Quant. transfer filtrate to 50 mL vol. flask with aid of small portions  $\text{H}_2\text{O}$ , dil. to vol., and mix. Proceed immediately with detn of PAS. Det. INH as soon as practicable, preferably  $\leq 4$  hr after prepn of  $\text{NaHCO}_3$  soln.

(b) (*Applicable when filtration with vacuum is not feasible.*)—Weigh sample as in (a), and transfer quant. to 40–50 mL r-b centr. tube. Cautiously add, in small portions, freshly prepd soln of 1.5 g  $\text{NaHCO}_3$  in 20 mL  $\text{H}_2\text{O}$ . Agitate well after each addn, avoiding loss from foaming by occasionally adding few drops of ether. After all  $\text{NaHCO}_3$  soln is added, continue agitation until effervescence stops. Centrf. 5–10 min at ca 2000 rpm and decant supernate into 50 mL vol. flask. Add 10 mL  $\text{H}_2\text{O}$  to tube, using rubber policeman to wash down wall, to disintegrate residual cake, and to secure uniform suspension. Centrf. as before, and combine supernate wash with original ext. Repeat washing with three 5 mL portions  $\text{H}_2\text{O}$ , dil. combined aq. phases to vol., mix, and filter thru fluted paper. Proceed as in (a).

37.114

**p-Aminosalicylic Acid (PAS)**

From aq.  $\text{NaHCO}_3$  ext, transfer aliquot contg ca 150 mg PAS to 500 mL vol. flask and dil. to vol. with  $\text{H}_2\text{O}$ . Transfer 10 mL aliquot to 250 mL vol. flask, add 12.5 mL concd pH 7 buffer, and dil. to vol. with  $\text{H}_2\text{O}$ . Measure *A* of this diln in 1 cm cell at 299 (max.), 244 (min.), and 325 nm against 1 + 19 diln of the buffer. (With instruments suitable for *A* readings in range 1.0–1.5, use 2 cm cell thruout method or modify diln so that concn of substance is twice that specified.) Calc. baseline  $A_B$ :

$$A_B = A_{299} - (0.3210 A_{244} + 0.6790 A_{325}).$$

Accurately weigh ca 50 mg finely powd pure PAS, dissolve in 2 mL alcohol, add 5 mL 0.1*N* NaOH, and dil. with  $\text{H}_2\text{O}$  to exactly 500 mL. Transfer 25 mL aliquot to 200 mL vol. flask, add 10 mL concd pH 7 buffer, and dil. to vol. with  $\text{H}_2\text{O}$ . Det. *A* at 244, 299, and 325 nm as above. Det.  $A_B$ , and from this value and that obtained from sample soln, calc. amt PAS in sample.

37.115

**Isonicotinylhydrazine (INH)**

(Caution: See 51.011, 51.040, and 51.056.)

Transfer 20 mL aliquot of the  $\text{NaHCO}_3$  ext to 125 mL separator, add 0.5 mL benzaldehyde, shake 15 min, and let stand 10 min. Ext with six 20 mL portions  $\text{CHCl}_3$ , filter exts thru compact pledget of absorbent cotton into 150 mL beaker, and evap. filtrate on steam bath in air current until residue has only faint odor of benzaldehyde. Rinse down wall of beaker with little  $\text{CHCl}_3$  to conc. residue at bottom, and evap. to dryness. Add 1–2 mL  $\text{CHCl}_3$ , evap. again to dryness on steam bath in air current, and heat residue few min. Repeat  $\text{CHCl}_3$  and heating treatment

until hot residue of benzyldine isonicotinylhydrazine (BINH) is odorless, or has at most very faint odor of benzoic acid (there must be no sweet odor or odor of benzaldehyde; take care to avoid loss from spattering).

Dissolve residue in  $\text{CHCl}_3$  and transfer quant. to separator with addnl solv. Add  $\text{CHCl}_3$  to vol. of 20–30 mL, shake with 10 mL freshly prepd 5%  $\text{NaHCO}_3$ , and filter  $\text{CHCl}_3$  layer thru compact pledget of absorbent cotton. Wash aq. soln with three 10 mL portions  $\text{CHCl}_3$ , passing each wash thru filter, and evap. combined  $\text{CHCl}_3$  exts to dryness on steam bath in air current.

Dissolve residue of BINH in alcohol without heat, and dil. to exactly 100 mL with alcohol. Dil. 5 mL aliquot of this soln to exactly 200 mL with alcohol, and det. *A* of diln (1 cm cell; alcohol blank) at 302 (max.) and 375 nm. Subtract reading at 375 (background *A* from impurities) from that at 302 nm. Difference represents *A* from BINH at 302 nm.

Dissolve ca 20 mg, accurately weighed, of pure BINH in alcohol and dil. to exactly 100 mL. Dil. 10 mL aliquot of this soln to exactly 250 mL with alcohol and det. *A* at 302 nm. Using this value and that due to BINH obtained from sample, calc. equiv. amt of BINH in sample.  $\text{BINH} \times 0.6088 = \text{INH}$ .

**37.116 ★ Dinitrophenol (or Its Sodium ★ Compound) (44)—Official Final Action**

Bromination method. See 32.331–32.332, 10th ed.

**Glyceryl Guaiacolate (45)—Official Final Action****Polarographic Method**

(Not applicable in presence of salicylate)

37.117

**Apparatus**

- (a) *Polarograph*.—See 20.001.  
 (b) *Micro or std cell, H-shaped*.—Satd calomel electrode, with 3% KCl-agar plug.  
 (c) *Water bath*.—Maintain at  $65 \pm 1^\circ$  in freely circulating  $\text{H}_2\text{O}$  bath.

37.118

**Reagents**

- (a) *Potassium nitrate soln*.—1*M*. Weigh 50.5 g  $\text{KNO}_3$  into 500 mL vol. flask, dil. to vol. with  $\text{H}_2\text{O}$ , and mix.  
 (b) *Dilute sulfuric acid soln*.—10% (v/v). Dil. 20 mL  $\text{H}_2\text{SO}_4$  (1+1) to 100 mL with  $\text{H}_2\text{O}$  and mix.  
 (c) *Gelatin maximum suppressor*.—1 mg/mL. Accurately weigh 100 mg gelatin (Difco Laboratories No. 0143-01; or Knox Gelatine Inc., Johnstown, NY 12095, unflavored gelatin No. 1) into 100 mL vol. flask, and dissolve in small amt  $\text{H}_2\text{O}$  on steam bath. Cool, dil. to vol. with  $\text{H}_2\text{O}$ , and mix. Prep. fresh daily, as needed.  
 (d) *Supporting electrolyte*.—pH 10.4. Weigh 53.5 g  $\text{NH}_4\text{Cl}$  into 1 L vol. flask, add 400 mL  $\text{NH}_4\text{OH}$ , mix to dissolve, and dil. to vol. with  $\text{H}_2\text{O}$ .  
 (e) *Glyceryl guaiacolate std soln*.—1 mg/mL. Accurately weigh 25 mg glyceryl guaiacolate std into 25 mL vol. flask. Dil. to vol. with  $\text{H}_2\text{O}$  and mix.

37.119

**Preparation of Sample**

(a) *Sirups*.—Quant. transfer accurately measured portion of sample contg ca 100 mg glyceryl guaiacolate to 125 mL separator, add 10 mL dil.  $\text{H}_2\text{SO}_4$ , and ext with four 20 mL portions  $\text{CHCl}_3$ , and then with 15 mL  $\text{CHCl}_3$ . Collect  $\text{CHCl}_3$  exts in second separator and wash with 10 mL  $\text{H}_2\text{O}$ . Filter  $\text{CHCl}_3$  layer thru pledget of  $\text{CHCl}_3$ -washed cotton into 100 mL vol. flask. Rinse

★ Surplus method—see inside front cover.

separator with 2–3 mL  $\text{CHCl}_3$  and add wash to vol. flask. Dil. to vol. with  $\text{CHCl}_3$  and mix.

(b) *Tablets*.—Det. av. wt/tablet. Grind without loss to pass No. 60 sieve. Accurately weigh powder contg ca 50 mg glyceryl guaiacolate and transfer to 125 mL separator. Add 10 mL  $\text{H}_2\text{O}$  and shake 2 min. Proceed as in (a), beginning "... add 10 mL dil.  $\text{H}_2\text{SO}_4$ , ..."

### 37.120 *Derivative Formation*

Pipet duplicate 10 mL aliquots for sirups or 20 mL aliquots for tablets of prep'd soln into sep. 100 mL vol. flasks and carefully evap. to dryness with aid of air only. Add 10 mL  $\text{H}_2\text{O}$  to each and shake to dissolve glyceryl guaiacolate. Label flasks as sample and blank. Pipet 10 mL glyceryl guaiacolate std soln into third 100 mL vol. flask and label as std.

Pipet 3 mL  $\text{H}_2\text{SO}_4$  (1+1) into each flask. Pipet 3 mL 1M  $\text{KNO}_3$  into std and sample flasks and 3.0 mL  $\text{H}_2\text{O}$  into blank flask. Place flasks in 65° const temp. bath. When solns reach 65°, heat addnl 60 min. Remove from bath and cool to room temp. Into each flask pipet 25 mL electrolyte soln and 5 mL gelatin soln, cool to room temp., dil. to vol. with  $\text{H}_2\text{O}$ , and mix thoroly.

### 37.121 *Polarography*

Transfer soln to polarographic cell and bubble N thru for 5 min with micro H cell or 10 min with std H cell at moderate rate. Polarograph from -0.2 to -0.9 v against satd calomel ref. electrode. Measure ht of diffusion current ( $I_d$ ) at half-wave potential as follows: Draw line tangent to top of residual current extending to half-wave potential point. Draw line along top of limiting current extending to half-wave potential point. Measure vertical drop at half-wave potential between the 2 lines in convenient units.

Det. glyceryl guaiacolate concn by comparing wave ht of sample soln with those of std and blank solns.

Subtract diffusion current ( $I_b$ ) of blank, if any, from sample only. Perform all detns at same current sensitivity and within same time span.

### 37.122 *Calculations*

(a) *Sirup*.—mg Glyceryl guaiacolate/mL  

$$= 100 \times (I_d - I_b) \times C / (I'_d \times V),$$

(b) *Tablets*.—mg Glyceryl guaiacolate/tablet  

$$= 50 \times (I_d - I_b) \times C \times W_t / (I'_d \times W_s),$$

where  $I_d$ ,  $I_b$ , and  $I'_d$  = diffusion current of sample, blank, and std solns, resp.;  $C$  = mg glyceryl guaiacolate/mL std soln;  $W_t$  and  $W_s$  = av. tablet wt and wt sample taken, resp.; and  $V$  = mL liq. prep'n taken.

### Guaiacol (46)—Official Final Action

#### 37.123 *Reagent*

*Hydriodic acid*.—Sp gr 1.7. Boil HI 30 min under reflux with excess of hypophosphorous acid. When cool, transfer to dark, g-s bottle. Do not leave bottle unstoppered more than few min.

#### 37.124 *Apparatus*

*Methoxyl apparatus*.—See Fig. 47:07.

#### 37.125 *Determination*

Place aliquot of alk. guaiacol soln (guaiacol dissolved in 1% NaOH) contg 0.03–0.06 g guaiacol in boiling flask and evap. soln just to dryness on steam bath in air current. For solid guaiacol compds, weigh 0.06–0.10 g and transfer directly to flask. Complete detn by method for methoxyl group, 47.050,

beginning "Add 2.5 mL melted *phenol* from wide-tip pipet ...". Boil 30 min and titr. with 0.1N  $\text{Na}_2\text{S}_2\text{O}_3$ , 1 mL 0.1N  $\text{I}^-$  = 0.00207 g guaiacol; 0.00229 g guaiacol carbonate; 0.00404 g K guaiacol sulfonate.

### Hexylresorcinol (47)—Official Final Action

#### 37.126 *Reagents*

(a) *Sodium thiosulfate std soln*.—0.1N. Prep. as in 50.037.

(b) *Purified methanol*.—Purify if necessary as follows: Add enough Br to com. MeOH to give bright yellow soln, heat to bp on  $\text{H}_2\text{O}$  bath, and boil 5 min. Cool, and carefully decolorize by adding 10%  $\text{NaHSO}_3$  soln dropwise until just colorless.

#### 37.127 *Standardization of Thiosulfate*

Add 30 mL 0.1N KBr-KBrO<sub>3</sub>, 4.002(g), and 10 mL purified MeOH to 150 mL g-s flask. Wet stopper. Add 5 mL HCl, stopper flask, immediately place under running tap  $\text{H}_2\text{O}$ , and swirl until flask cools to room temp.; continue to shake 5 min after adding HCl. Cautiously loosen stopper and add 5 mL 20% KI soln. Swirl gently to liberate I, wash stopper, and titr. with  $\text{Na}_2\text{S}_2\text{O}_3$  soln. Add starch paste when soln is pale yellow.

#### 37.128 *Determination*

Transfer 0.07–0.09 g sample to 150 mL g-s flask. Add 10 mL MeOH, (b), and swirl gently to dissolve sample. Add 30 mL 0.1N KBr-KBrO<sub>3</sub>. Moisten stopper, add 5 mL HCl, stopper flask, and immediately hold under running  $\text{H}_2\text{O}$  while swirling vigorously. When cooled to room temp. (ca 1 min), remove from tap and shake vigorously 5 min after adding HCl. Cautiously loosen stopper and add 5 mL 20% KI soln. Swirl gently, wash stopper with little  $\text{H}_2\text{O}$ , add 1 mL  $\text{CHCl}_3$ , and titr. with  $\text{Na}_2\text{S}_2\text{O}_3$  soln while swirling flask gently. Near end point, stopper flask and shake vigorously to remove halogen from  $\text{CHCl}_3$ . When soln becomes pale yellow, add starch paste and continue titrn. End point is reached when starch-I color does not return during 30 sec of vigorous shaking. 1 mL 0.1N KBr-KBrO<sub>3</sub> soln = 0.00486 g hexylresorcinol.

### 8-Hydroxyquinoline Sulfate (Oxyquinoline) (48)

#### Official Final Action

##### Method I

(For amts of hydroxyquinoline sulfate between 25 and 250 mg. Use this method whenever nature of sample permits.)

#### 37.129 *Extraction*

(a) *Interfering substances absent*.—Dissolve sample in ca 75 mL  $\text{H}_2\text{O}$  and add 5 mL HCl.

(b) *Nonoily preparations*.—Ext preferably from soln alk. with  $\text{NaHCO}_3$  or borax. If extn from such medium is impracticable, or if compds of  $\text{NH}_3$  or heavy or alk. earth metals are present, add Me red, 50.014(a), and adjust with NaOH and/or HCl to slight acidity. Add  $\text{NaOAc} \cdot 3\text{H}_2\text{O}$  in proportion of 1 g/100 mL soln. If heavy or alk. earth metals are present, also add 2 mL  $\text{HOAc}$ /100 mL soln.

Ext adjusted soln with enough 20 mL portions  $\text{CHCl}_3$ . For alk. or slightly acid soln, usually 6 extns suffice; when extra  $\text{HOAc}$  has been added, 10–12 extns are needed. Test for complete extn by adding little HCl (1+9) to last portion, evapg  $\text{CHCl}_3$  on steam bath, adjusting to 70°, and adding drop of 0.01N KBr-KBrO<sub>3</sub> and then drop of Me red; Me red should be bleached immediately.

Ext combined  $\text{CHCl}_3$  exts with five 10 mL portions HCl (1+9). If salicylic acid, volatile oils, etc., are present, wash each acid portion with same 10 mL ether. If sample contains phenol or

other volatile interfering substances not completely removed by preceding process, boil acid soln to remove them, keeping vol. ca const by adding more H<sub>2</sub>O.

(c) *Ointments, etc.*—Transfer sample to separator with 50 mL ether, and ext with five 10 mL portions HCl (1+9). If salicylic acid, etc., is present, wash each acid portion with same 10 mL ether. Add Me red; make just alk. with 10% NaOH soln, then just acid with dil. HCl, and proceed as in (b), beginning "Add NaOAc.3H<sub>2</sub>O . . ."

**37.130****Determination**

Adjust acid soln (a), (b), or (c), to 50° and keep at this temp. during titrn by reheating occasionally. Add drop (or more) Me red **50.014(a)**, from buret and titr. with 0.1*N* KBr-KBrO<sub>3</sub>, **4.002(g)**. (Color of liq. gradually changes from brown-orange to yellow; add more indicator whenever soln becomes yellow. At slightly beyond halfway point, dibromohydroxyquinoline may crystallize and adsorb dye. Disregard color of ppt and judge by that of soln. By dilg to ≤0.1 g hydroxyquinoline sulfate/100 mL, formation of ppt can be avoided.) End point is reached when, after waiting 10 sec for absorption of last drop of KBr-KBrO<sub>3</sub> soln and adding drop of indicator, it is bleached almost immediately. Timing for addn of drop of indicator at end point is important, as proper conditions prevail only brief period.

Read vols of 2 solns consumed. Measure 10 mL Me red into erlenmeyer, add 2 mL HCl, and titr. with 0.1*N* KBr-KBrO<sub>3</sub>. Correct main titrn for vol. of Br consumed by measured vol. indicator used in titrn. 1 mL 0.1*N* KBr-KBrO<sub>3</sub> = 0.00508 g (C<sub>9</sub>H<sub>7</sub>NO)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub>·H<sub>2</sub>O.

**37.131 Method II**

(For amts between 2 and 10 mg)

Ext as in **37.129**. Start titrn as in **37.130**, using 0.01*N* KBr-KBrO<sub>3</sub>, and dild Me red (1 vol. Me red, **50.014(a)**, 4 vols H<sub>2</sub>O, and enough NaOH to dissolve dye) instead of stronger reagents. Use as little indicator as possible. When near end point, shown by more rapid consumption of indicator, heat to 70°, and complete titrn at this temp.

**Methyl Salicylate (49)—Official Final Action****37.132****Reagents**

(a) *Salicylic acid std soln.*—20 µg/mL. Dissolve 0.2500 g reagent grade salicylic acid in 95 mL CHCl<sub>3</sub> in 250 mL vol. flask and dil. to vol. with alcohol. Dil. 2.00 mL to 100 mL with alcohol.

(b) *Sodium bicarbonate soln.*—Dissolve 5 g NaHCO<sub>3</sub> in 100 mL of H<sub>2</sub>O to which 1 drop HCl has been added.

**37.133****Determination**

Prep. sample diln, if necessary, to contain ca 5% Me salicylate. Pipet 5 mL sample or diln into 50 mL ether-pet ether mixt. (1+1) in separator and wash with two 5 mL portions cold, freshly prepd NaHCO<sub>3</sub> soln. Discard unemulsified aq. phases. Ext org. layer with two 5 mL portions 5% NaOH soln followed by two 5 mL portions H<sub>2</sub>O. Let phases sep. 5 min and drain unemulsified aq. layers into another separator. Wash combined exts with 10 mL pet ether and drain aq. phase into another separator. Acidify cautiously with HCl (litmus paper) and ext with four 20 mL and one 15 mL portions CHCl<sub>3</sub>. Filter each ext thru CHCl<sub>3</sub>-moistened plug of cotton into 250 mL vol. flask. Dil. to vol. with alcohol and transfer 2.00 mL aliquot to 100 mL vol. flask.

Dil. to vol. with alcohol and det. *A* at max. (ca 305 nm). Calc. as salicylic acid by comparison with *A* of std soln. Salicylic acid × 1.1016 = Me salicylate.

**Phenolphthalein in Chocolate Preparations (50)  
Official Final Action****37.134****Reagents**

(a) *Potassium hydroxide soln.*—5±0.1*N*.

(b) *Iodine soln.*—0.5*N*. Dissolve 12.7 g KI in 10 mL H<sub>2</sub>O, add 6.35 g I, and when dissolved add 12 mL KOH soln, (a). Dil. to 100 mL with H<sub>2</sub>O.

(c) *Sodium sulfite soln.*—Dissolve 12.6 g anhyd. Na<sub>2</sub>SO<sub>3</sub> in H<sub>2</sub>O and dil. to 100 mL with H<sub>2</sub>O.

**37.135****Preparation of Alcoholic Extract**

Chill sample until hard; then reduce to granules by grating, shaving, or grinding. Mix thoroly. Accurately weigh amt of prep sample contg ca 0.1 g phthln into gooch with thin asbestos mat or fritted glass disk. Ext fat with 5, 4, and 3 mL CCl<sub>4</sub>, using slight suction towards end. Place crucible on bell jar app. Ext phthln from sample with several portions hot alcohol, collecting filtrate in 300 mL tall beaker. Wash underside of crucible free from phthln with hot alcohol (ca 50 mL is enough for extn and washings). Evap. combined alc. exts to dryness on steam bath.

**37.136****Determination**

Dissolve residue at room temp. in 1–1.5 mL KOH soln. (Alk. phthln soln is unstable in air, and phthln should be converted to tetraiodo compd within 1 hr.) Add piece of ice (ca 40 g) and 7–8 mL I soln. Add HCl dropwise from buret, using stirring rod, to complete pptn. If ppt and supernate are not brown, add addnl I soln to ensure excess. Again dissolve ppt by adding KOH from buret dropwise, with stirring. Wash down any unreacted phthln adhering to sides of beaker with little H<sub>2</sub>O. (Soln should now be blue to blue-purple.)

Repeat pptn with acid and resoln with alkali 3 more times, adding small piece of ice if necessary. Then add 1–1.5 mL Na<sub>2</sub>SO<sub>3</sub> soln to blue alk. soln and filter into 250 mL beaker thru gooch with thin asbestos mat or coarse fritted glass disk. Wash crucible several times with H<sub>2</sub>O. Acidify filtrate with HCl, using few mL excess, and heat on steam bath 20–30 min, stirring occasionally. Decant hot supernate thru weighed gooch (with asbestos mat or medium fritted glass disk). Wash white to cream-colored ppt in beaker by decantation with hot H<sub>2</sub>O few times. Completely transfer ppt to the gooch and wash with hot H<sub>2</sub>O until filtrate is clear and gives neg. test for Cl. When app. has cooled and ppt has been sucked fairly dry, wash ppt several times with pet ether, using suction toward end. Dry tetraiodo-phenolphthalein to const wt at 110–130°. Wt ppt × 0.3873 = wt phthln.

**37.137 Phenolphthalein in Emulsions (51)  
Official Final Action**

Shake sample well, preferably in mech. shaker, 10 min. Accurately weigh amt of sample contg ca 0.1 g phthln from weighing buret directly into centr. bottle. Add 100 mL alcohol-ether (1+3), stopper bottle, shake vigorously, and then centr. until clear. Decant into separator. Wash residue in bottle twice with 10 mL portions solv. mixt., adding these washings to separator. Dissolve residue in bottle in few mL H<sub>2</sub>O and reppt gums with 50 mL solv. mixt. Shake and centr. as before, decanting into separator. Wash residue and bottle with three 10 mL portions solv. mixt. and add these to separator. Dissolve residue in few mL H<sub>2</sub>O and test for complete extn with NaOH.

Shake exts in separator repeatedly with 25 mL portions ca 0.1*N* NaOH until phthln is completely removed, as shown by absence of color. Combine alk. exts in another separator and acidify soln with dil. H<sub>2</sub>SO<sub>4</sub> (1+15).

Ext phthln by shaking acid mixt. repeatedly with 10 mL portions ether. Test for complete extn with NaOH soln. Combine ether exts in 150 mL beaker, evap. to dryness, and det. phthln as in **37.136**, omitting filtration of alk. soln.

#### Phenolphthalein in Tablets

#### 37.138 ★ *Ether Extraction Method* (52) ★ *Official Final Action*

See **37.138**, 12th ed.

#### 37.139 ★ *Phenolsulfonates* (53)—*Official Final Action* ★

Bromination method. See **32.342**, 10th ed.

#### Thymol (54)—*Official Final Action*

#### 37.140 *Preparation of Solution*

Weigh 2 g pulverized thymol, transfer to 500 mL vol. flask, and add 25 mL 25% NaOH soln. Agitate until thymol is dissolved and dil. to vol. at 20° with H<sub>2</sub>O.

#### 37.141 *Method I*

#### *Determination*

Transfer 25 mL aliquot thymol soln to 250 mL g-s erlenmeyer, add 20 mL hot HCl (1+1), and immediately add 1–3 mL less than theoretical vol. 0.1*N* KBr-KBrO<sub>3</sub>, **4.002(g)**. Warm to 70–80°, add 2 drops 0.1% aq. Me orange, and titr. slowly with KBr-KBrO<sub>3</sub> soln, swirling vigorously after each addn. When red of Me orange has been bleached, add 2 drops titrg soln, stopper, shake vigorously 10 sec, add 1 drop Me orange, and again shake vigorously 10 sec. Continue addn of KBr-KBrO<sub>3</sub> soln, 2 drops at time, shaking each time until red disappears. Add 1 drop Me orange, shake vigorously, and if red does not disappear, repeat alternate addn of 2 drops KBr-KBrO<sub>3</sub> soln and 1 drop Me orange, shaking after each addn as before until red disappears. Calc. mL KBr-KBrO<sub>3</sub> soln used to % thymol. 1 mL 0.1*N* KBr-KBrO<sub>3</sub> = 0.003756 g thymol. Reserve mixt. in titrg flask for **37.142**.

#### 37.142 *Method II*

To cooled mixt. from titrn, **37.141**, add 3–5 mL addnl KBr-KBrO<sub>3</sub> soln. (If sample has not been previously analyzed by **37.141**, det. approx. vol. of KBr-KBrO<sub>3</sub> soln to use by adding 20 mL HCl (1+1) to 25 mL soln, **37.140**, heating to ca 80°, and titrg slowly with KBr-KBrO<sub>3</sub> soln, while vigorously swirling flask, to yellow color maintained 1 min.) Stopper, shake, add 1 g solid KI, wash sides of flask and stopper with H<sub>2</sub>O, and titr. I liberated by excess KBr-KBrO<sub>3</sub> soln with 0.1*N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, using starch soln, **6.005(f)**, as indicator. Calc. vol. Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln used in terms of KBr-KBrO<sub>3</sub> soln, deduct from total vol. KBr-KBrO<sub>3</sub> soln added, and calc. to % thymol.

#### 37.143 *Thymol in Antiseptics* (55)—*Official Final Action*

(*Caution*: See **51.011**, **51.039**, and **51.054**.)

If alc. content is not known, make preliminary alcohol detn.

Transfer 50 mL sample (or aliquot contg 0.05–0.10 g thymol) to Pt or porcelain evapg dish. Add 6–7 mL 50% NaOH soln, mix well, and carefully dealcoholize by placing dish on steam bath before elec. fan. Evap. vol. slightly more than amt of alcohol present. (If >30% alcohol is present, dil. with H<sub>2</sub>O to alc. content of 25%. In no case should evapn be carried >70% of original vol.) Transfer soln to 125 mL separator, washing out evapg dish with enough H<sub>2</sub>O to bring vol. to ca 75 mL.

Ext alk. soln with two 20 mL portions pet ether. Wash combined exts once with 5–10 mL 5% NaOH soln and add washings to aq. layer. Ext aq. soln contg thymol, together with Na salts of boric, benzoic, and salicylic acids, with ether as in **36.001**, using 20, 15, 15, 10, and 10 mL. Use 8–10 extns if prepn contains glycerol. Combine ether exts, transfer to 250 mL g-s erlenmeyer, and add 5 mL recently prepd alc. KOH soln, **28.025**. Evap. most of ether, using steam bath and elec. fan but do not evap. entirely to dryness. Leave 6–8 mL residue and add to it 75 mL hot H<sub>2</sub>O (80–90°) and 10 mL HCl.

Immediately add 1–3 mL less than theoretical vol. 0.1*N* KBr-KBrO<sub>3</sub>, **4.002(g)**, swirling constantly. Add 2 drops aq. 0.1% Me orange and titr. slowly with KBr-KBrO<sub>3</sub> soln as in **37.141**.

Test for complete extn by shaking aq. layer with two 15–20 mL portions ether and titrg the thymol, if any, in ether exts. Add this titrn to that obtained for main ether ext.

If theoretical amt of thymol present is not known, add 2 drops Me orange and titr. slowly, swirling constantly during addn of KBr-KBrO<sub>3</sub> soln until red color is bleached. Continue as in **37.141**, beginning "... add 2 drops titrg soln, stopper, shake vigorously ..."

*Caution*: To avoid loss of thymol by volatilization, both evapn of alcohol and later evapn of ether must be done carefully.

#### Acenocoumarol, Dicoumarol (Bishydroxycoumarin), Phenprocoumon, Potassium Warfarin, and Sodium Warfarin (56)—*Official Final Action*

#### 37.144

#### *Principle*

Basic soln of drug is acidified and extd with CHCl<sub>3</sub> or CHCl<sub>3</sub>-pyrimidine-propylene glycol (for dicoumarol), and *A* of extd material is read in flowcell at 308 nm.

#### 37.145

#### *Apparatus*

(a) *Automatic analyzer*.—AutoAnalyzer with following modules (Technicon Instruments Corp.): Sampler II with 20/hr (2:1) cam; proportioning pump I; manifold (Fig. **37.02**).

(b) *Filter*.—Fill 50 × 5 mm id glass tubing completely, but loosely, with glass wool.

(c) *Spectrophotometer*.—Double-beam spectrophtr which records *A* at fixed wavelength, with 10 mm flowcell (Arthur H. Thomas Co., No. 8495-L10) (2 mm flowcell (Beckman Instruments, No. 565411) for dicoumarol).

(d) *Ultrasonic generator*.—Model 11, 150 watt (Heat Systems-Ultrasonic, Inc., 38 E Mall, Plainview, NY 11803).

#### 37.146

#### *Reagents*

(a) *Chloroform*.—H<sub>2</sub>O-washed and filtered thru paper. Prep. fresh daily. (Use in all except dicoumarol detn.)

(b) *Chloroform-pyridine-propylene glycol soln*.—Mix 50 mL pyridine with 50 mL propylene glycol and dil. to 1 L with CHCl<sub>3</sub>. Use in dicoumarol assay.

(c) *Acenocoumarol std soln*.—0.08 mg/mL. Accurately weigh ca 20 mg acenocoumarol std in 250 mL vol. flask. Dissolve in ca 100 mL 0.01*N* NaOH with aid of ultrasonic generator and dil. to vol. with 0.01*N* NaOH.

(d) *Dicoumarol (bishydroxycoumarin) std soln*.—0.25 mg/mL. Accurately weigh ca 25 mg USP Ref. Std Bishydroxycoumarin in 100 mL vol. flask. Dissolve in ca 50 mL 0.01*N* NaOH with aid of ultrasonic generator and dil. to vol. with same solv. Prep. fresh daily.

(e) *Phenprocoumon std soln*.—0.12 mg/mL. Accurately weigh ca 30 mg USP Ref. Std Phenprocoumon in 250 mL vol. flask. Dissolve in ca 100 mL 0.01*N* NaOH with aid of ultrasonic generator and dil. to vol. with 0.01*N* NaOH.

★ Surplus method—see inside front cover.

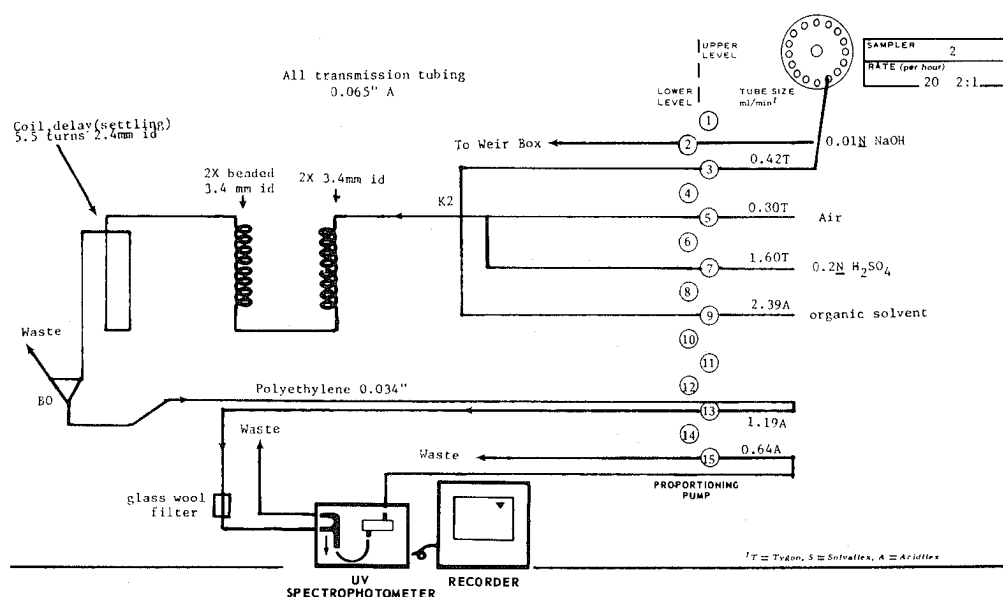

FIG. 37:02—Flow diagram for automated analysis for acenocoumarol, dicumarol, phenprocoumon, potassium warfarin, and sodium warfarin

(f) *Warfarin std soln.*—0.1 mg/mL. Accurately weigh ca 25 mg USP Ref. Std Warfarin into 250 mL vol. flask, and dissolve and dil. to vol. with 0.01N NaOH.

### 37.147

#### Preparation of Sample

Disintegrate individual tablet or capsule or disperse weighed composite in accurately measured vol. 0.01N NaOH to give drug concn (mg/mL) as follows: acenocoumarol 0.08, dicumarol 0.25, phenprocoumon 0.12, Na or K warfarin 0.10. Use ultrasonic generator ca 10 min to assure tablet disintegration. Let suspension stand 1.5 hr with occasional mixing.

### 37.148

#### Analytical System

Sample is withdrawn, segmented with air, and acidified with 0.2N H<sub>2</sub>SO<sub>4</sub>. Solv., (a) or (b), is added, mixed in beaded coil, and phases are sepd in BO fitting. Org. phase contg extd drug is debubbled, and A of soln at 308 nm is measured in 10 mm flowcell (2 mm flowcell for dicumarol).

### 37.149

#### Start-Up

Pump alcohol thru solv. line 10 min; then pump solv. thru line 5 min. Place remaining tubes in their resp. solns and let system equilibrate 20–30 min. Calibrate spectrophtr at 2 or 3 absorbances. Adjust mask in ref. compartment of spectrophtr to set desired baseline.

### 37.150

#### Shut-Down

Place acid, base, and sampling lines in H<sub>2</sub>O, leave solv. line in its reservoir, and pump 5 min. Remove acid, base, and sampling lines from H<sub>2</sub>O and continue pumping 5 min to purge system of H<sub>2</sub>O. Place solv. line in alcohol and pump 5 min. Remove line and pump system dry.

### 37.151

#### Determination

Fill sample cups in following order: 4 cups std soln, 5 cups sample soln, 1 cup std soln, 5 cups sample soln, etc. Place 2 cups std soln at end of each run. (Extra cups of std solns at start and end of sampling pattern are used to overcome carryover effect in transitions from wash soln to std soln and vice versa.

Three extra cups at beginning and 1 extra cup at end should suffice, but det. exact number needed for equilibrium by experiment. System should give uniform response for at least final pair of extra std cups before sample pattern is started.) Start Sampler II. After last cup has been sampled, let system operate until steady baseline is obtained. Draw tangent to initial and final baselines. Subtract baseline to det. net A and A' for each sample and std peak, resp. Discard values for first 3 and last std peaks and calc. av. std A'.

mg Na (or K) warfarin in portion taken =  $1.071$  (or  $1.124$ )  $\times$  (A/A')  $\times$  C  $\times$  D, where 1.071 and 1.124 = ratios of MW of Na and K warfarin to warfarin, resp.; C = concn of std in mg/mL, and D = diln factor.

mg Acenocoumarin, dicumarol, or phenprocoumon in portion taken = (A/A')  $\times$  C  $\times$  D.

## SULFONAMIDE DRUGS

### Mixtures of Sulfonamides

#### ★ Paper Chromatographic Method (57) ★ Official First Action

### 37.152

#### Apparatus

(a) *Chromatographic chamber.*—See 29.006(f); with trays approx. 3.8  $\times$  31.6 cm (1.5  $\times$  8.5"), glass lid, and fasteners for ascending chromatgy.

(b) *Chromatographic paper.*—8  $\times$  8" (20  $\times$  20 cm) sheets, Whatman No. 1, or equiv.

(c) *Viewing apparatus.*—Use light source having 160 microwatts/sq cm at 253.7 nm at distance of 46 cm suspended  $\geq$  23 cm above paper. Fluorescence Analysis Cabinet C-3F with model C-81 lamps is convenient (Spectronics Corporation, 956 Brush Hollow Rd, Westbury, NY 11590).

### 37.153

#### Reagents

(Use reagent grade materials except as noted.)

(a) *Mobile solvent.*—50 mL CH<sub>2</sub>Cl<sub>2</sub>.

(b) *Immobile solvent.*—Dissolve 30 mL redistd formamide in 70 mL acetone. Prep. fresh daily.

★ Surplus method—see inside front cover.

- (c) *Sodium nitrite soln.*—0.1%. Prep. fresh daily.  
 (d) *Ammonium sulfamate soln.*—0.5%.  
 (e) *N-(1-naphthyl) ethylenediamine dihydrochloride (NED) soln.*—See 42.017(d).  
 (f) *Dilute hydrochloric acid.*—Approx. 0.12*N*. Dil. 10 mL HCl to 1 L.  
 (g) *Chromatographic rinse soln.*—Dil. 9 vols. MeOH with 1 vol. NH<sub>4</sub>OH (2+5).  
 (h) *Sulfacetamide, sulfadiazine, sulfamerazine, and sulfamethazine.*—USP Ref. Stds.  
 (i) *Sulfathiazole std.*—NF XI grade, or equiv.

**37.154****Preparation of Standards**

(a) Prep. sep. std solns for each component of sample under test. Accurately weigh ca 10 mg Ref. Std, transfer quant. with MeOH rinses to 10 mL vol. flask contg 0.3 mL NH<sub>4</sub>OH, dissolve, and dil. to vol. with MeOH. Transfer 1.0 mL of this soln to 100 mL vol. flask and dil. to vol. with 0.12*N* HCl. MeOH solns of stds are stable  $\geq 1$  week; acid solns,  $\geq 1$  month.

(b) Prep. mixed chromatgc std soln by transferring 1 mL of each MeOH soln of required stds to small g-s flask and mixing. This std is used to identify components of test sample on chromatogram.

**37.155****Preparation of Sample**

Det. av. wt/tablet and pulverize. Accurately weigh amt powder contg ca 50 mg of each sulfonamide and transfer with MeOH rinses to 50 mL vol. flask contg 3 mL NH<sub>4</sub>OH. Shake occasionally during 15 min and dil. to vol. with MeOH. Mix thoroly.

**37.156****Determination**

Draw pencil line parallel to and 2.5 cm from bottom of paper. Mark line at points 2.5 and 5 cm from each edge of paper. Impregnate paper by dipping it in immobile solv. 30 sec. (For convenience, roll paper and dip rolled sheet into 100 mL graduate contg immobile solv.) Remove paper, drain 10 sec, and blot between filter papers. Place impregnated paper on dry filter paper and air dry 3–5 min. With 100  $\mu$ L pipet and by repeated applications, streak sample soln along starting line, limiting delivery to ca 20  $\mu$ L/streak. Evap. solv. with gentle air current between applications. Keep within marks 5 cm from either edge, and make streak as narrow as possible by uniform motion of pipet along starting line. Rinse outside tip of pipet with drop (ca 10  $\mu$ L) of chromatgc rinse soln, and streak rinse along starting line between 5 and 2.5 cm points at right edge. Repeat rinsing twice and finally blow out pipet. (Restricting application of rinse to sep. area prevents diffusion of major streak.) Apply 10  $\mu$ L spot of mixed chromatgc std soln at mark 2.5 cm from left edge. Dry paper 5 min before developing it.

Place mobile solv. in tray in chromatgc tank, cover tank, and let equilibrate ca 15 min. Remove cover, and without delay, place 7–10 mL H<sub>2</sub>O in second tray and suspend paper so that it dips into mobile solv. Seal edges of lid to tank with masking tape and develop chromatogram 1 hr. Remove paper from tank and air dry 5 min.

Place chromatogram on dry sheet of filter paper and view it under shortwave UV light. Sulfacetamide (lowest *R<sub>f</sub>*) is light-sensitive and must be protected from excessive exposure. Circle sulfacetamide band and cover circled area with dry sheet of filter paper. Outline remaining bands and confirm identity of sample components by matching *R<sub>f</sub>* values with those of spots from chromatgc stds.

Cut marked zones from paper. Cut each zone into 5 or 6 pieces and place in 50 mL g-s conical flask. Add 20.0 mL 0.12*N* HCl to each flask. Let stand 15–30 min; swirl each flask  $\geq 5$  times. Filter

solns thru dry glass wool into test tube, discarding first 4–5 mL filtrate. Pipet 5 mL aliquot of each sample soln into sep. 10 mL vol. flasks. Pipet 3 mL aliquot of each required std soln into sep. 10 mL vol. flasks. To each flask, and to blank flask contg 5 mL 0.12*N* HCl, add 1 mL NaNO<sub>2</sub> soln and 0.10 mL HCl. Let stand 5 min with frequent swirling. Then add 1 mL NH<sub>4</sub> sulfamate soln, swirl frequently, and let stand 5 min. Finally add 1 mL NED soln, swirl, adjust to vol. with H<sub>2</sub>O, mix, and let stand  $\geq 15$  but  $\leq 60$  min. Record spectra of sample and std solns between 440 and 700 nm against blank. Draw baseline, and det. corrected *A* at max., ca 545 nm.

mg Individual sulfonamides/g sample taken

$$= 2000 \times (A/A') \times (C/W),$$

where *A* and *A'* refer to sample and std solns, resp. (baseline-corrected), *C* = mg std in aliquot taken, and *W* = g sample.

**Trisulfapyrimidines (58)—Official Final Action****Total Trisulfapyrimidines****37.157****Principle**

Total trisulfapyrimidines in sample are detd by coupling with *N*-1-naphthyl ethylenediamine.2HCl (NED), recording spectra of samples and stds between 660 and 480 nm. Individual sulfonamides are sep'd by TLC and their ratios detd spectrophtrically after coupling with NED.

**37.158****Reagents**

(a) *Ammonia-methanol soln.*—Dil. 5 mL NH<sub>4</sub>OH to 100 mL with MeOH.

(b) *Sulfamerazine std soln.*—Approx. 6  $\mu$ g/mL acid soln. Accurately weigh calcd amt USP Ref. Std Sulfamerazine, previously dried, and dissolve in NH<sub>4</sub>OH-MeOH soln; dil. quant. and stepwise with MeOH to obtain soln contg ca 120  $\mu$ g/mL. Transfer 5.0 mL to 100 mL vol. flask and dil. to vol. with 0.12*N* HCl, 37.153 (f). Acidic soln is stable  $\geq 1$  month.

(c) *Dilute ammonia soln.*—Dil. 400 mL NH<sub>4</sub>OH to 1 L with H<sub>2</sub>O.

(d) *N-1-naphthyl ethylenediamine dihydrochloride (NED) soln.*—0.1%. Prep. fresh before use.

**37.159****Preparation of Sample**

(a) *Tablets.*—Accurately weigh finely powd portion contg ca 180 mg total sulfonamides and transfer to 50 mL vol. flask, using 10 mL dil. NH<sub>4</sub>OH, (c). Let stand ca 15 min, mixing occasionally, dil. to vol. with MeOH, and centr. portion to clarify (Soln I). Dil. 5.0 mL clarified soln to 250 mL with H<sub>2</sub>O; dil. 4.0 mL of this soln to 50 mL with H<sub>2</sub>O (Soln II).

(b) *Suspensions.*—Shake in original container to ensure homogeneity, let stand long enough for entrapped air to rise, and invert carefully just before removing portion for weighing. Det. sp gr by weighing 100 mL in tared 100 mL vol. flask. Thoroly mix and weigh portion contg 180 mg total sulfonamides and proceed as in (a).

**37.160****Determination**

Pipet 5.0 mL aliquots sulfamerazine std soln and prep'd Soln II into sep. 10 mL vol. flasks. Add 1.0 mL HCl (1+1) to each flask, mix, and cool. (Solns must be at room temp. for quant. results.) Add 1.0 mL 0.1% NaNO<sub>2</sub>, mix well, and let stand 2 min. Add 1.0 mL 0.5% NH<sub>4</sub> sulfamate, and mix. After 2 min, add 1.0 mL NED soln, (f). Mix and adjust to vol. with H<sub>2</sub>O. Record spectra of samples and stds against H<sub>2</sub>O between 660 and 480 nm (peak ca 545 nm) within 15–60 min. Correct *A* by subtracting *A* at 660 nm from peak *A* at ca 545 nm.

$$\text{mg Total sulfapyrimidines in sample} = (A/A') \times 31.25C,$$

where  $A$  and  $A'$  = corrected  $A$  of dild assay soln and sulfamerazine std soln, resp., and  $C$  =  $\mu\text{g}$  sulfamerazine/mL std soln.

#### Ratio of Sulfadiazine:Sulfamerazine:Sulfamethazine

##### 37.161

##### Reagents and Apparatus

(a) *Chromatographic identification standards*.—Prep. sep. solns of USP Ref. Std Sulfadiazine, Sulfamerazine, and Sulfamethazine in  $\text{NH}_4\text{OH}$ -MeOH soln, 37.158(a), to contain ca 1 mg/mL each.

(b) *Developing solvent*.— $\text{CHCl}_3$ -MeOH- $\text{NH}_4\text{OH}$  (30+12+1).

(c) *Thin layer plate*.—20 × 20 cm, coated 0.25 mm thick with silica gel GF (Brinkmann Instruments, Inc.). Divide into 2 approx. equal parts by scraping thin vertical line thru coating.

##### 37.162

##### Thin Layer Chromatography

Line suitable chromatgc tank with blotting paper. Wet bottom of tank and paper with developing solv., seal tank, and let equilibrate 30 min. Apply ca 50  $\mu\text{L}$  centrfd Soln I to starting line of thin layer plate in streak ca 8 cm long (not to extend within 1 cm of plate edge or center line), using N stream. (It is not necessary to spot accurately measured vol.) On other half of plate, spot sep. 10  $\mu\text{L}$  chromatgc identification stds, evenly spaced, under N stream. Develop plate in tank equilibrated 0.5 hr, letting solv. migrate 10–15 cm above starting line. Air dry plate, locate bands under shortwave UV light, and circle with stylus. Remove silica gel from each band by scraping onto glazed weighing paper, and transfer to sep. 50 mL g-s centr. tubes. Add 10.0 mL 0.1N NaOH to each tube, shake 3 min, and centr. Transfer 5.0 mL aliquots of each supernate to 10 mL vol. flasks. Add 1.0 mL HCl (1+1) to each flask, mix, and cool. (Soln must be at room temp. for quant. results.) Develop color and record spectra as in 37.160.

##### 37.163

##### Calculations

Calc. fraction of each sulfapyrimidine in total sulfapyrimidines as follows:

$$\text{Sulfadiazine fraction} = 0.947A_d/T$$

$$\text{Sulfamerazine fraction} = A_r/T$$

$$\text{Sulfamethazine fraction} = 1.053A_m/T,$$

where  $A_d$ ,  $A_r$ , and  $A_m$  = corrected  $A$  of the sulfadiazine, sulfamerazine, and sulfamethazine bands, resp., and  $T = 0.947A_d + A_r + 1.053A_m$ .

#### Sulfadiazine and Sulfamerazine (59)—Official Final Action

##### 37.164

##### Reagents

(a) *Citrate buffer soln*.—Dissolve 37 g  $\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 2\text{H}_2\text{O}$  in  $\text{H}_2\text{O}$ , add 32 mL HCl, and dil. to 250 mL with  $\text{H}_2\text{O}$ .

(b) *2-Thiobarbituric acid (TBA) soln*.—Recrystallize acid twice from  $\text{H}_2\text{O}$ . Dissolve 5 g recrystd acid in 20 mL 1N NaOH dild with 500 mL  $\text{H}_2\text{O}$ . Add 250 mL citrate buffer soln and adjust to pH 2.0. Reagent is stable when stored in g-s bottle in refrigerator.

##### 37.165

##### Determination

(a) *Sulfadiazine*.—To powd sample contg ca 0.1 g mixed sulfonamides, add 50 mL 1N HCl. Shake intermittently 10 min, filter if necessary, and dil. filtrate and washings to 100 mL with  $\text{H}_2\text{O}$ . To 5 mL aliquot, add 7.5 mL 1N HCl and dil. to 100 mL. Designate this soln (contg ca 5 mg mixed sulfonamides/100 mL 0.1N HCl) as Soln X. To 1.0 mL aliquot Soln X in g-s test tube, add 10.0 mL TBA soln, stopper, and heat 1 hr at 100°. Weigh tube before and after heating, and compensate for any loss by addn of  $\text{H}_2\text{O}$ . Similarly treat 1.0 mL std contg 25  $\mu\text{g}$  sulfadiazine

in 0.1N HCl and blank contg 0.1N HCl. Det.  $A$  of sample and of std,  $A'$ , at 532 nm against blank.

mg Sulfadiazine in sample taken =  $50 A/A'$ .

(b) *Sulfamerazine*.—Det.  $A_r$  of Soln X, and  $A'_d$  and  $A'_m$  of solns contg 5.0 mg pure sulfadiazine and sulfamerazine, resp., in 100 mL 0.1N HCl, at 305 nm against 0.1N HCl blank. Then  $A$  of Soln X due to sulfadiazine ( $A_d$ ) =  $A'_d \times (\text{mg sulfadiazine in Soln X}/5.0)$ , and  $A$  due to sulfamerazine ( $A_m$ ) =  $A_r - A_d$ .

mg Sulfamerazine in sample taken =  $100 A_m/A'_m$ .

#### 37.166 Sulfadiazine in Presence of Other Sulfonamides (57)—Official Final Action

Det. sulfadiazine as in 37.165(a) from soln prepd to contain ca 25  $\mu\text{g}$  sulfadiazine/mL 0.1N HCl.

#### 37.167 ★ Sulfanilamide (60)—Official Final Action ★

Hydrolysis and distn and titrn of  $\text{NH}_3$  produced. See 36.483, 11th ed.

### OTHER IMIDE DRUGS

#### Bendroflumethiazide (61)—Official First Action

##### 37.168

##### Principle

Bendroflumethiazide is eluted from 0.1M  $\text{Na}_2\text{CO}_3$ -diat. earth column with  $\text{HOAc-CHCl}_3$  and measured directly by UV spectrophotometry.

##### 37.169

##### Apparatus

(a) *Chromatographic tube and tamping rod*.—See 37.002.

(b) *Diatomaceous earth*.—See 36.002.

##### 37.170

##### Reagents

(a) *Sodium carbonate soln*.—0.1M. Dissolve 10.6 g  $\text{Na}_2\text{CO}_3$  in  $\text{H}_2\text{O}$ , dil. to 1 L with  $\text{H}_2\text{O}$ , and mix.

(b) *Bendroflumethiazide std solns*.—(1) *Stock soln*.—0.4 mg/mL. Accurately weigh ca 20 mg USP Bendroflumethiazide Ref. Std into small beaker, add 5 mL DMSO, and mix with glass rod until dissolved. Transfer quant. to 50 mL vol. flask with MeOH and dil. to vol. with MeOH. (2) *Working soln*.—0.012 mg/mL. Transfer 3.0 mL stock soln to 100 mL vol. flask contg 2 mL MeOH and 2 drops HCl. Dil. to vol. with  $\text{CHCl}_3$ .

##### 37.171

##### Preparation of Sample

Finely powder tablets to pass No. 60 sieve. Transfer portion contg 15–20 mg bendroflumethiazide to 50 mL vol. flask. Add 5 mL DMSO, wetting entire sample. (Caution: DMSO can be harmful. Avoid skin contact by wearing heavy rubber gloves. Use effective fume removal device.) Let stand 10 min with frequent mixing. Dil. to vol. with 0.1M  $\text{Na}_2\text{CO}_3$ . Filter portion thru paper, discarding first few mL.

##### 37.172

##### Preparation of Columns

(a) *Lower layer*.—Mix 2 g diat. earth with 1 mL 0.1M  $\text{Na}_2\text{CO}_3$  in 150 mL beaker, transfer to tube, and tamp to uniform mass.

(b) *Upper layer*.—Mix 4 g diat. earth with 3.0 mL sample soln, transfer to tube, and tamp. Dry-wash flask contg sample mixt. with 1 g diat. earth and 2–3 drops  $\text{H}_2\text{O}$ ; transfer to column and tamp. Top with glass wool pad.

★ Surplus method—see inside front cover.

**37.173****Determination**

(Use H<sub>2</sub>O-washed solvs thruout. Caution: See 51.039 and 51.062.)

Let 75 mL isooctane elute thru column and discard eluate. Use 100 mL vol. flask contg 2 drops HCl in 5 mL MeOH as receiver, and elute column with 90 mL CHCl<sub>3</sub>-HOAc (98+2). Dil. to vol. with CHCl<sub>3</sub>.

Det. *A* of sample and working std solns at max., ca 271 nm (*a* = 48.8), in 1 cm cells with spectrophtr against CHCl<sub>3</sub>-HOAc (98+2) as ref.

**37.174****Identification**

Macerate portion finely powd tablets contg 4–5 mg bendroflumethiazide with H<sub>2</sub>O. Transfer to 125 mL separator, using small portions H<sub>2</sub>O, and dil. to ca 15 mL. Ext with three 20 mL portions CHCl<sub>3</sub>, collecting CHCl<sub>3</sub> in 100 mL beaker. Evap. to dryness on steam bath with aid of air current. Dissolve residue in small vol. MeOH and evap. to dryness. Compare IR spectrum in KBr matrix of residue with that of ref. std previously recrystd from alcohol.

**Methimazole (1-Methyl-2-Mercaptoimidazole) (62)****Official Final Action**

(Caution: See 51.011, 51.040, and 51.056.)

**37.175****Apparatus**

- (a) *Chromatographic tube*.—200 × 22 mm.
- (b) *Spectrophotometer*.—Recording double-beam IR spectrophtr, with 2 mm cells and NaCl windows.

**37.176****Reagents**

- (a) *Diatomaceous earth*.—See 36.002.
- (b) *Methimazole std*.—Store in desiccator over P<sub>2</sub>O<sub>5</sub> when not in use.

**37.177****Column Chromatography**

Transfer amt of freshly ground tablet mixt. contg 10 mg methimazole to 100 mL beaker, add 3 mL H<sub>2</sub>O, and mix thoroly to wet sample. Add 4 g diat. earth and mix thoroly. Transfer in 2 equal portions to chromatgc tube contg pledget of glass wool and pack tightly. Rinse beaker with 0.5 g diat. earth and add to column; top with glass wool pad. Rinse beaker with 150 mL H<sub>2</sub>O-washed isooctane (redistd) and add rinses to column. Let last drops of isooctane drain from column before proceeding. Discard isooctane eluate.

Rinse beaker with three 5 mL portions H<sub>2</sub>O-washed CHCl<sub>3</sub> and add rinses to column. Collect eluate. Elute methimazole with 200 mL H<sub>2</sub>O-washed CHCl<sub>3</sub>, maintaining solv. head ≤ 75 mm (3") during elution. Combine CHCl<sub>3</sub> eluates, and evap. at ca 40–60° with air stream to ca 10 mL, washing down sides of beaker with small portions CHCl<sub>3</sub> during evapn. Do not heat excessively, since methimazole may oxidize. Quant. transfer conc. to 30 mL beaker with several small portions CHCl<sub>3</sub>. Evap. solv. at ca 30–40° under air stream. (Make certain all traces of isooctane are removed.) Dry residue in vac. over anhyd. P<sub>2</sub>O<sub>5</sub> 30 min. (If necessary, store residue over desiccant in dark; methimazole oxidizes on standing.)

**37.178****Determination**

Add 5 mL CS<sub>2</sub> to residue in beaker, cover with watch glass, and warm to dissolve. Cool and quant. transfer soln to 10 mL vol. flask with CS<sub>2</sub>. Repeat with two 2 mL portions CS<sub>2</sub>, cool, transfer to flask, and dil. to vol.

Prep. std soln methimazole in CS<sub>2</sub>, with warming, to contain exactly 1.00 mg/mL. Record quant. IR spectra of sample and std

solns between 7.6 and 8.4 μm in 2 mm NaCl cells. Measure baseline *A* values of 7.83 μm max., using minima at 7.7 and 8.3 μm.

$$\text{mg Methimazole/tablet} = A \times (C'/A') \times 10 \times (T/W),$$

where *A* and *A'* = baseline values for sample and std, resp.; *C'* = mg/mL std soln; *T* and *W* = av. wt/tablet and sample wt, resp., in mg.

Identify samples by comparing IR spectra of quant. solns with spectrum of std over 2–15 μm, using CS<sub>2</sub> as blank.

**Methyldopa and Chlorothiazide in Combination (63)****Official Final Action****37.179****Reagents and Apparatus**

(a) *Ion exchange resin*.—AG 50W-X4, 100–200 mesh, H<sup>+</sup> form (BioRad Laboratories, 32nd and Griffin Aves, Richmond, CA 94804). Strongly acidic nuclear sulfonic groups on polystyrene lattice.

(b) *Acidic methanol*.—Add 1 drop HCl to 500 mL anhyd. MeOH. (Dissoln of thiazides is retarded by >2 drops.)

(c) *Methanolic hydrochloric acid*.—1*N*. Dil. 42 mL HCl to 500 mL with anhyd. MeOH.

(d) *Ion exchange tube*.—150 × 12 mm id, with replaceable coarse fritted glass disk, Teflon stopcock, and Buna-N "O" ring seal (Kontes Glass Co., No. K-422280, or equiv.).

(e) *Methyldopa std soln*.—30 μg/mL. Accurately weigh ca 3 mg std, previously dried at 105° overnight, and dissolve in 100.0 mL 1*N* methanolic HCl.

(f) *Chlorothiazide std soln*.—10 μg/mL. Accurately weigh ca 1 mg std, previously dried 1 hr at 105°, and dissolve, with heat if necessary, in 100.0 mL acidic MeOH.

**37.180****Preparation of Column**

Prep. slurry of 2 g resin with 20–25 mL anhyd. MeOH and transfer to tube with stopcock closed and contg plug of glass wool under fritted disk. Let resin settle by gravity; then top with small pledget of glass wool. Column need not be tamped. Drain solv., wash column with several portions anhyd. MeOH, and discard all washings. Prevent column from drying before use by maintaining head of 2–3 mL MeOH or H<sub>2</sub>O.

When resin is being used for first time and on completion of sepns, wash thoroly with 15–20 mL HCl-MeOH (1+1) to recondition resin. With stopcock closed and glass wool removed, stir resin to obtain slurry, let settle, and drain. Repeat twice. Finally, wash resin first with H<sub>2</sub>O until excess acid is removed and then with several portions anhyd. MeOH. Store under H<sub>2</sub>O.

**37.181****Preparation of Sample**

Det. av. wt/tablet and pulverize to pass No. 80 sieve. Accurately weigh amt contg ca 25 mg chlorothiazide into 50 mL beaker. Add 15 mL acidic MeOH and heat carefully on steam bath ca 30 min to dissolve active ingredients. Cool, transfer to 50 mL vol. flask, and dil. to vol. with acidic MeOH.

**37.182****Determination**

(a) *Chlorothiazide*.—Collect eluate in 100 mL vol. flask at rate of 2–3 drops/sec. Transfer 10.0 mL sample soln to prepd column. After sample soln has entered column, rinse down sides with three 2 mL portions anhyd. MeOH, letting each portion sink into resin completely before next addn. Do not agitate column mech. or by addn of solv. Complete elution with 50 mL anhyd. MeOH. Rinse column tip with acidic MeOH. Add 1 drop HCl to eluate and dil. to vol. with anhyd. MeOH. Further dil. 5.0 mL to 25.0 mL with acidic MeOH. Scan sample and std solns between 235 and

360 nm against acidic MeOH. Calc. chlorothiazide from *A* at max., ca 277 nm. Proceed immediately to methylidopa detn before column dries.

(b) *Methylidopa*.—Place another 100 mL vol. flask under column after elution in (a). Elute with 50 mL 1*N* methanolic HCl at 2–3 drops/sec. Rinse column tip with 1*N* methanolic HCl. Dil. to vol. with 1*N* methanolic HCl and further dil. to concn of ca 30 µg methylidopa/mL. Scan sample and std solns between 230 and 360 nm against 1*N* methanolic HCl. Calc. methylidopa from *A* at max., ca 280 nm.

#### Nikethamide

##### Gas Chromatographic Method (64)—Official First Action

37.183

##### Principle

Nikethamide prepn is dild with acetone contg anthracene as internal std and detd by GLC with flame ionization detector. Method is applicable to levels of nikethamide normally encountered in injectable prepn (25% w/v). Store all solns contg anthracene in low-actinic glassware and complete detn within 1 day.

37.184

##### Apparatus and Reagents

(Caution: See 51.046.)

(a) *Gas chromatograph*.—Packard Model 838, or equiv., with flame ionization detector and 1.8 m (6') × 4 mm id glass tube packed with 4% XE-60 on 80–100 mesh Gas-Chrom Q (Applied Science Laboratories, Inc., precoated, or equiv., or prep. as in 37.185). Operating conditions: temps (°)—column 180, injection port 210, detector 210; gas flows (mL/min)—N carrier gas 56, air 200, H 25; sensitivity 10<sup>-9</sup> amp full scale, attenuation 1×. Before use, condition column 24 hr at 240–250° with 100±20 mL N/min. If necessary, vary column temp. or gas flow to attain retention times of ca 6 and 4–5 min for anthracene and nikethamide, resp. Also vary detector sensitivity or injection vol. (4–7 µL) to attain peak hts of 50–90% full scale.

(b) *Internal std soln*.—0.8 mg/mL. Accurately weigh ca 0.8 g anthracene, heat ca 15 min on steam bath with acetone to dissolve, and dil. to 100 mL with acetone.

(c) *Nikethamide std solns*.—(1) *Stock soln*.—Approx. 1.0 mg nikethamide (ICN-K&K Laboratories)/mL acetone, accurately prepd. (2) *Working soln*.—Approx. 0.5 mg nikethamide/mL acetone. Accurately measure equal vols (≥5.0 mL each) of (b) and (c)(1) and mix thoroly.

37.185

##### Preparation of Column

Wash tube and small amt fine glass wool with 5% (v/v) dichlorodimethylsilane in toluene; rinse with acetone and dry thoroly at room temp. (Caution: Dichlorodimethylsilane is toxic. Avoid contact with skin and eyes. Use effective fume removal device.) Dissolve 3.0 g XE-60 in 100 mL CHCl<sub>3</sub>. Transfer soln to 250 mL beaker and slowly add 20.0 g 80–100 mesh Gas-Chrom Q with const but gentle stirring. Continue stirring ca 30 sec after adding all support. Place beaker under bell jar and apply vac. Carefully increase vac. and hold at max. ca 1 min to degas.

Swirl slurry rapidly and transfer in small portions to buchner fitted with 9 cm Whatman No. 4 paper. Maintain vac. 5 min after last portion is added. Air dry coated support 1 hr by spreading on smooth surface, and oven-dry addnl hr at 105°.

Plug column exit with small wad of silanized fine glass wool and thru-hole septum. Apply vac. to exit and slowly add coated support thru injection end, tapping very gently to aid compaction. Pack to within 1 cm of area heated by flash heater. Plug inlet with ≤3 mm wad of silanized fine glass wool and condition as in 37.184(a).

37.186

##### Determination

Pipet 5 mL sample (25% w/v com. prepn) into 250 mL vol. flask, dil. to vol. with acetone, and mix. Dil. 20.0 mL to 100 mL with acetone (dil. sample soln). Prep. assay soln by mixing equal vols of dil. sample soln and internal std soln. Inject 5 µL working std soln into gas chromatograph and record chromatogram; then inject 5 µL assay soln and record.

$$\% \text{ Nikethamide (w/v)} = (P \times I' \times C' \times 100) / (P' \times I \times C),$$

where *P* and *P'* = peak hts (or areas) of nikethamide in assay soln and working std soln, resp.; *I* and *I'* = peak hts (or areas) of anthracene (internal std) in assay soln and working std soln, resp.; *C'* = g nikethamide/mL working std soln; and *C* = mL sample/mL assay soln.

##### 37.187 Propylthiouracil (65)—Official Final Action

Start and complete detn on same day.

Transfer accurately weighed sample contg ca 150 mg propylthiouracil to 200 mL vol. flask, and transfer 150.0 mg pure propylthiouracil to another 200 mL vol. flask as std. To each flask add 150 mL NH<sub>4</sub>OH (1+13), washing down necks. Shake flasks moderately and continuously 1 min to dissolve propylthiouracil. Dil. to vols with NH<sub>4</sub>OH (1+13) and mix.

Filter sample soln, discarding first 25 mL filtrate. Dil. 20 mL aliquot clear filtrate to 200 mL with H<sub>2</sub>O in vol. flask (or 25 mL aliquot to 250 mL) and mix. Dil. 20 mL aliquot of this soln to 200 mL in vol. flask (or 25 mL aliquot to 250 mL) and mix. Prep. same double diln of std soln to obtain final concn of 0.0075 mg/mL.

Det. *A* of final solns of std and sample against H<sub>2</sub>O blank in silica cells in spectrophtr at 234 nm. Apply cell corrections unless same cell is used for both std and sample. Calc. propylthiouracil content of sample.

##### 37.188 ★ Thiouracil (2-Mercapto-4-hydroxypyrimidine) ★ (66)—Official First Action

Bromination method. See 32.394, 10th ed.

##### Thiazides (67)—Official Final Action

37.189

##### Principle

Benzthiazide, hydrochlorothiazide, or hydroflumethiazide is eluted from 0.2*N* NaOH-diat. earth column with HOAc-ethyl ether, extd into 0.2*N* NaOH, and detd by UV spectrophotometry. Chlorothiazide is eluted from 0.2*M* K<sub>2</sub>HPO<sub>4</sub>-diat. earth column with HOAc-ethyl ether, extd into 0.2*N* HCl, and detd by UV spectrophotometry. Methyclothiazide is eluted from 0.1*M* NaHCO<sub>3</sub>-diat. earth column with CHCl<sub>3</sub> and measured directly by UV spectrophotometry.

37.190

##### Apparatus and Reagents

(a) *Chromatographic tube and tamping rod*.—See 37.002.

(b) *Diatomaceous earth*.—See 36.002.

(c) *Dipotassium phosphate solns*.—0.2 and 0.1*M*, 34.85 and 17.43 g K<sub>2</sub>HPO<sub>4</sub>/L, resp.

(d) *Benzthiazide, hydrochlorothiazide, and hydroflumethiazide std solns*.—Prep. with ether-satd 0.2*N* NaOH. (1) *Benzthiazide*.—3.0 mg USP Ref. Std/200 mL. (2) *Hydrochlorothiazide*.—2.0 mg USP Ref. Std/200 mL. (3) *Hydroflumethiazide*.—2.0 mg USP Ref. Std/200 mL.

(e) *Chlorothiazide std solns*.—(1) *Stock soln*.—1.4 mg/mL. Accurately weigh ca 70 mg USP Chlorothiazide Ref. Std into small beaker, add 2 mL dimethylsulfoxide (DMSO), and mix with

★ Surplus method—see inside front cover.

glass rod until dissolved. Transfer quant. to 50 mL vol. flask, using 0.2M  $K_2HPO_4$ , and dil. to vol. with same solv. (2) *Working soln.*—0.014 mg/mL. Dil. 2.0 mL stock soln to 200 mL with 0.2N HCl.

(f) *Methyclothiazide std solns.*—(1) *Stock soln.*—0.2 mg/mL. Accurately weigh 20 mg USP Methyclothiazide Ref. Std into 100 mL vol. flask and dil. to vol. with MeOH. (2) *Working soln.*—0.01 mg/mL. Dil. 10 mL stock soln to 200 mL with  $CHCl_3$ .

**37.191****Preparation of Sample**

Finely powder to pass No. 60 sieve.

(a) *Benzthiazide, hydrochlorothiazide, or hydroflumethiazide.*—Transfer portion contg 75 mg benzthiazide or 50 mg hydrochlorothiazide or hydroflumethiazide to 50 mL vol. flask, using 0.2N NaOH. Shake to dissolve completely and dil. to vol.

(b) *Chlorothiazide.*—Transfer portion contg ca 70 mg to small beaker and add 2.0 mL DMSO. Mix thoroly 2–3 min with glass rod to dissolve completely. Transfer to 50 mL vol. flask, using 0.2M  $K_2HPO_4$ , and dil. to vol. with same solv. Mix thoroly.

(c) *Methyclothiazide.*—Transfer portion contg ca 2 mg to 150 mL beaker. Add 2 mL MeOH and mix thoroly. Add 2 mL 0.1M  $NaHCO_3$  and mix.

**37.192****Preparation of Columns**

(a) *Benzthiazide, chlorothiazide, hydrochlorothiazide, or hydroflumethiazide.*—(1) *Lower layer.*—Mix 2 g diat. earth with 1 mL 0.2N NaOH (1 mL 0.1M  $K_2HPO_4$  for chlorothiazide) in 150 mL beaker, transfer to tube, and tamp to uniform mass.

(2) *Upper layer.*—Mix 3 g diat. earth with 2 mL sample soln, transfer to tube, and tamp. Dry-wash flask contg sample mixt. with 1 g diat. earth and 2–3 drops  $H_2O$ ; transfer to column and tamp. Top with glass wool pad.

(b) *Methyclothiazide.*—(1) *Lower layer.*—Mix 3 g diat. earth with 2 mL 0.1M  $NaHCO_3$  in 150 mL beaker, transfer to tube, and tamp to uniform mass.

(2) *Upper layer.*—Proceed as in (a)(2), except use 4 g diat. earth.

**37.193****Determination**

(Use  $H_2O$ -satd solvs thruout.)

(a) *Benzthiazide, hydrochlorothiazide, and hydroflumethiazide.*—Pass 50 mL  $CHCl_3$ , followed by 50 mL ether, thru column; discard eluate. Using 250 mL separator as receiver, elute column with 0.1 mL HOAc in 100 mL ether. Wash tip of column with ether. Add 65 mL isooctane to eluate and ext org. phase with three 50 mL portions 0.2N NaOH; combine NaOH soln in 200 mL vol. flask and dil. to vol.

Det. A of sample and std solns in 1 cm cells with spectrophtr against 0.2N NaOH as ref.

(b) *Chlorothiazide.*—Proceed as in (a), except use 0.25 mL HOAc in 100 mL ether, 50 mL isooctane, and 0.2N HCl instead of NaOH. Use 0.2N HCl as ref. solv.

(c) *Methyclothiazide.*—Pass 75 mL isooctane-ether (9+1) thru column; discard eluate. Use 200 vol. flask as receiver and elute column with 100 mL  $CHCl_3$ . Wash tip of column with ether. Add 10 mL MeOH and dil. to vol. with  $CHCl_3$ . Use  $CHCl_3$  as ref. solv.

Wavelength of max. A, and a of individual compds are as follows:

Compd	$\lambda$ Max., nm	Absorptivity
Benzthiazide	295	29.6
Chlorothiazide	278	32.4
Methyclothiazide	268	51.8
Hydrochlorothiazide	273	49.1
Hydroflumethiazide	273	45.4

**37.194****Identification**

(a) *Benzthiazide, hydrochlorothiazide, and hydroflumethiazide.*—Acidify portion sample soln with 1N HCl and ext with 50 mL ether. Evap. ether to dryness, add 5 mL alcohol, and evap. again. Compare IR spectrum in KBr matrix of residue with that of ref. std previously recrystd from alcohol.

(b) *Chlorothiazide.*—Transfer 5 mL prepd soln, 37.191(b), to 125 mL separator, add 10 mL  $H_2O$ , acidify with 1N HCl, and ext with 75 mL ether. Evap. ether to dryness. Add 5 mL alcohol to residue and evap. to dryness. Compare IR spectrum in KBr matrix of residue from 400 to 600  $cm^{-1}$  with that of ref. std previously recrystd from alcohol.

(c) *Methyclothiazide.*—Transfer portion sample contg ca 4 mg active ingredient to 125 mL separator, add 20 mL 0.1M  $NaHCO_3$ , and ext with ca 75 mL ether. Proceed as in (b).

**Polythiazide (68)—Official Final Action**

(Applicable to formulations contg vanillin)

**37.195****Principle**

Vanillin, which interferes in method, is condensed thru aldehyde group with primary amine group of sulfanilic acid to form strongly polar and  $H_2O$ -sol. Schiff's base, which is retained in aq. immobile phase of column. Less polar polythiazide is eluted with mobile phase, ether-isooctane, and detd by UV spectrophotometry.

**37.196****Apparatus and Reagents**

(Use  $H_2O$ -washed solvs thruout.)

(a) *Chromatographic tube and tamping rod.*—See 37.002.

(b) *Diatomaceous earth.*—See 36.002.

(c) *Dilute ammonium hydroxide.*—1N. Dil. 17 mL  $NH_4OH$  to 250 mL with  $H_2O$ .

(d) *Ammonium sulfanilate soln.*—6%. Dissolve 6.0 g sulfanilic acid in 1N  $NH_4OH$  and dil. to 100 mL with 1N  $NH_4OH$ .

(e) *Polythiazide std soln.*—10  $\mu g/mL$ . Accurately weigh ca 100 mg polythiazide, transfer to 100 mL vol. flask, and dil. to vol. with MeOH. Further dil. 10 mL of this soln to 100 mL with MeOH and 10 mL dild soln to 100 mL with MeOH.

**37.197****Preparation of Sample**

Accurately weigh sample contg ca 1 mg polythiazide and transfer to 150 mL beaker. Add 0.25 mL dimethylsulfoxide (DMSO) and mix thoroly to wet entire sample. Let stand 3–4 min.

**37.198****Preparation of Column**

(a) *Lower layer.*—Mix 6 g diat. earth, (b), and 5 mL  $NH_4$  sulfanilate soln in 150 mL beaker, transfer to tube, and tamp to uniform mass.

(b) *Upper layer.*—Add 4 mL  $NH_4$  sulfanilate soln to sample soln, and mix. Add 4 g diat. earth, mix, transfer to tube, and tamp to uniform mass. Dry-wash beaker with 1 g diat. earth and few drops  $H_2O$ , transfer to tube, and tamp. Top with glass wool pad.

**37.199****Determination**

Pass 100 mL isooctane thru column; discard eluate. Elute polythiazide with 100 mL isooctane-ether (1+1), receiving eluate in 250 mL beaker. Immediately evap. eluate to dryness. Dissolve residue in small amt MeOH and transfer quant. to 100 mL vol. flask. Dil. to vol. with MeOH. Filter thru glass wool, discarding first 20 mL. Det. A of sample and std solns against MeOH in 1 cm cell at max., ca 268 nm.

## 38. Drugs: Alkaloid and Related Bases

### ALKALOIDS, OPIUM

#### 38.001 Microchemical Tests—Official Final Action

See 36.095–36.097 and Table 36.03, and 36.106–36.108.

#### 38.002 General Titration Method (7)—Official Final Action

(Caution: See 51.011, 51.040, and 51.056.)

Det. av. wt/tablet or other unit and grind to fine powder. Accurately weigh sample equiv. to 100–200 mg alkaloid and transfer to separator with ca 20 mL H<sub>2</sub>O. Add 1 mL H<sub>2</sub>SO<sub>4</sub> (1+9) and ext with three 25 mL portions CHCl<sub>3</sub>. (Extn from acid soln is not necessary in absence of CHCl<sub>3</sub>-sol. acidic or neut. components.) Add ca 1 mL NH<sub>4</sub>OH (use excess solid NaHCO<sub>3</sub> for apomorphine or physostigmine) and ext with four 25 mL portions CHCl<sub>3</sub> (use CH<sub>2</sub>Cl<sub>2</sub> for ephedrine and CHCl<sub>3</sub>-isopropanol (4+1) for morphine). Use correspondingly larger vols of solv. if larger vols aq. soln are required, as in case of sirups or with excessive amts of excipients. Check alky of soln after first extn by touching indicator paper to stopper. If not distinctly alk., add addnl NH<sub>4</sub>OH. Check for complete extn by evapg 1 mL final ext to dryness; if more than trace of residue remains, ext with addnl portions solv. Filter ext thru plug of cotton or fine glass wool, previously wet with CHCl<sub>3</sub>, into 200 mL erlenmeyer. Complete detn by either of following methods ((a) must be used for arecoline and cocaine):

(a) Evap. combined exts on steam bath with air current to ca 10 mL. Add measured excess 0.02N H<sub>2</sub>SO<sub>4</sub> and continue evapn to remove solv. Cool, add Me red, and titr. excess acid with 0.02N NaOH.

(b) Evap. combined exts on steam bath with air current to dryness. Dissolve residue in ca 2 mL MeOH, heating if necessary. Add Me red, and titr. with 0.02N H<sub>2</sub>SO<sub>4</sub> to faint pink. If alkaloid

is not completely dissolved, heat gently to complete soln. Add ca 40 mL freshly boiled, cooled H<sub>2</sub>O, and complete titrn.

See Table 38.01 for titrn factors.

#### 38.003 Apomorphine in Tablets—Official Final Action

See 38.002.

#### 38.004 Codeine in Tablets—Official Final Action

See 38.002.

#### Codeine in Presence of Antihistamines (2) Official Final Action

(Applicable to sirups contg codeine with pyrilamine, methapyrilene, prophepyridamine, and similar antihistamines)

#### 38.005

Apparatus

See 37.002.

#### 38.006

Reagents

(a) *Triethylamine*.—If blank A, 38.008, is >0.010, purify as follows: Reflux 100 mL Et<sub>3</sub>N with 20 mL H<sub>2</sub>O and 2 g Na hydrosulfite ≥8 hr. Wash with four or five 20 mL portions H<sub>2</sub>O, dry by either distg into Dean-Stark trap or by salting-out with anhyd. K<sub>2</sub>CO<sub>3</sub>, and then distil, collecting first 75 mL. Store over anhyd. Na<sub>2</sub>CO<sub>3</sub> or K<sub>2</sub>CO<sub>3</sub>. (Caution: See 51.011, 51.040, and 51.052.)

(b) *Codeine std soln*.—Accurately weigh ca 100 mg codeine sulfate.5H<sub>2</sub>O (or other salt), dissolve in MeOH, transfer to 100

Table 38.01 Titration Factors for Alkaloids

Alkaloid	Formula	mg/mL 0.02N H <sub>2</sub> SO <sub>4</sub>
Apomorphine hydrochloride	C <sub>17</sub> H <sub>17</sub> O <sub>2</sub> N.HCl.½H <sub>2</sub> O	6.25
Arecoline hydrobromide	C <sub>8</sub> H <sub>13</sub> O <sub>2</sub> N.HBr	4.72
Atropine	C <sub>17</sub> H <sub>23</sub> NO <sub>3</sub>	5.79
Atropine sulfate	(C <sub>17</sub> H <sub>23</sub> NO <sub>3</sub> ) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub> .H <sub>2</sub> O	6.95
Cocaine hydrochloride	C <sub>17</sub> H <sub>21</sub> O <sub>4</sub> N.HCl	6.80
Codeine sulfate	(C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub> .5H <sub>2</sub> O	7.87
Codeine phosphate	C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N.H <sub>3</sub> PO <sub>4</sub> .1½H <sub>2</sub> O	8.49
Emetine hydrochloride	C <sub>29</sub> H <sub>40</sub> O <sub>4</sub> N <sub>2</sub> .2HCl	5.54
Ephedrine	C <sub>10</sub> H <sub>15</sub> ON	3.30
Ephedrine hydrochloride	C <sub>10</sub> H <sub>15</sub> ON.HCl	4.03
Ephedrine sulfate	(C <sub>10</sub> H <sub>15</sub> ON) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub>	4.29
Ethylmorphine hydrochloride	C <sub>19</sub> H <sub>23</sub> O <sub>3</sub> N.HCl.2H <sub>2</sub> O	7.72
Homatropine hydrobromide	C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N.HBr	7.13
Homatropine hydrochloride	C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N.HCl	6.24
Hydrocodone hydrochloride	C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N.HCl.H <sub>2</sub> O	7.08
Hydrocodone bitartrate	C <sub>18</sub> H <sub>21</sub> O <sub>3</sub> N.C <sub>4</sub> H <sub>6</sub> O <sub>6</sub> .2½H <sub>2</sub> O	9.89
Morphine hydrochloride	C <sub>17</sub> H <sub>19</sub> O <sub>3</sub> N.HCl.3H <sub>2</sub> O	7.52
Morphine sulfate	(C <sub>17</sub> H <sub>19</sub> O <sub>3</sub> N) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub> .5H <sub>2</sub> O	7.59
Physostigmine salicylate	C <sub>15</sub> H <sub>21</sub> O <sub>2</sub> N <sub>3</sub> .C <sub>7</sub> H <sub>6</sub> O <sub>3</sub>	8.27
Physostigmine sulfate	(C <sub>15</sub> H <sub>21</sub> O <sub>2</sub> N <sub>3</sub> ) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub>	6.49
Pilocarpine hydrochloride	C <sub>11</sub> H <sub>16</sub> O <sub>2</sub> N <sub>2</sub> .HCl	4.89
Pilocarpine nitrate	C <sub>11</sub> H <sub>16</sub> O <sub>2</sub> N <sub>2</sub> .HNO <sub>3</sub>	5.43
Procaine hydrochloride	C <sub>13</sub> H <sub>20</sub> O <sub>2</sub> N <sub>2</sub> .HCl	5.46
Strychnine	C <sub>21</sub> H <sub>22</sub> O <sub>2</sub> N <sub>2</sub>	6.69
Strychnine sulfate	(C <sub>21</sub> H <sub>22</sub> O <sub>2</sub> N <sub>2</sub> ) <sub>2</sub> .H <sub>2</sub> SO <sub>4</sub> .5H <sub>2</sub> O	8.57
Strychnine nitrate	C <sub>21</sub> H <sub>22</sub> O <sub>2</sub> N <sub>2</sub> .HNO <sub>3</sub>	7.95

mL vol. flask, and dil. to vol. with MeOH. 1 mL = 0.8067 mg codeine.H<sub>2</sub>O.

(c) *Chloroform*.—Use CHCl<sub>3</sub> satd with H<sub>2</sub>O thruout.

(d) *Diatomaceous earth*.—See 36.002.

**38.007****Preparation of Sample**

Prep. following 3 columns (columns II and III need not be quant.):

(a) *Column I*.—Pipet 2.0 mL sample, draining thoroly, into small beaker. Add 0.5 mL 1*N* NaOH and 3 g diat. earth. Mix thoroly and transfer quant. to tube, 37.002(a). Dry-wash beaker with small portion diat. earth and few drops H<sub>2</sub>O, and add to tube. Tamp column firmly with tamping rod, and press pad of glass wool on top.

(b) *Column II*.—Mix 3 g diat. earth and 2 mL 1*N* HNO<sub>3</sub>, and prep. column as in (a).

(c) *Column III*.—Mix 3 g diat. earth and 2 mL 1*N* H<sub>2</sub>SO<sub>4</sub>, and prep. column as in (a).

**38.008****Determination**

Arrange columns so that effluent from I flows into II and then into III. Pass 100 mL CHCl<sub>3</sub> over columns. Discard Column I which retains excipients.

Pass 50 mL CHCl<sub>3</sub> thru Column II (which retains antihistamine) onto III; then pass 25 mL CHCl<sub>3</sub> over III. Remove Column II.

To recover codeine, place 50 mL vol. flask contg 10 mL MeOH and 1 mL HCl under Column III. Pass 5 mL CHCl<sub>3</sub> contg 1 mL Et<sub>3</sub>N over column followed by 32 mL 1% Et<sub>3</sub>N in CHCl<sub>3</sub>. Dil. to vol. with CHCl<sub>3</sub> and det. A at 287 nm against CHCl<sub>3</sub>. (Film of Et<sub>3</sub>N.HCl may adhere to walls of cells. Rinse cells carefully with H<sub>2</sub>O and alcohol; then wipe clean before use.) Correct for blank A of mixt. of 10 mL MeOH, 1 mL Et<sub>3</sub>N, and 1 mL HCl dild to 50 mL with CHCl<sub>3</sub>. Also det. A' of std prepd by dilg 5 mL std soln contg 1 mg codeine salt/mL MeOH, to 50 mL with CHCl<sub>3</sub> and 5 drops HCl.

$$\text{mg Codeine salt in sample} = 5AC/A'$$

where A and A' refer to corrected A of sample and std, resp., and C = mg codeine salt/mL std soln.

**Codeine and Terpin Hydrate in Elixirs (3)**  
**Official Final Action**

**38.009****Reagents**

(a) *Color reagent*.—Either Folin-Denis reagent, 9.098(a), or phosphotungstic-phosphomolybdic acid reagent prepd as follows: To 100 g pure Na tungstate and 20 g phosphomolybdic acid (free from nitrates and NH<sub>4</sub> salts), add 100 g H<sub>3</sub>PO<sub>4</sub> and 700 mL H<sub>2</sub>O. Boil over free flame 1.5–2 hr, cool, filter if necessary, and dil. to 1 L with H<sub>2</sub>O. Equiv. amt of pure molybdic acid may be substituted for phosphomolybdic acid.

(b) *Terpin hydrate std soln*.—Accurately weigh ca 80 mg terpin hydrate, add 2 mL HOAc, and stir until terpin hydrate is almost dissolved. Add 10 mL alcohol, stir, and transfer to 100 mL vol. flask. Rinse dish with three 10 mL portions alcohol. Finally rinse few times with H<sub>2</sub>O and dil. to vol. with H<sub>2</sub>O. Soln keeps indefinitely.

(c) *Codeine std soln*.—See 38.006(b).

(d) *Water-saturated ether*.—Add 100 mL H<sub>2</sub>O to 200 mL ether in separator, shake, let stand 30 min, and discard H<sub>2</sub>O.

(e) *Acidified water-saturated chloroform*.—Sat. 300 mL CHCl<sub>3</sub> with H<sub>2</sub>O. After 30 min standing, transfer CHCl<sub>3</sub> to flask contg 3 mL HOAc.

(f) *Diatomaceous earth*.—See 36.002.

**38.010****Determination of Terpin Hydrate**

Pipet 5 mL sample into distg flask and add 100 mL satd NaCl soln, 35 mL alcohol, 2 mL HOAc, and 10 mL H<sub>2</sub>O. Distil, collecting 100 mL distillate.

Pipet 5 mL color reagent into 50 mL vol. flask. Cool under running H<sub>2</sub>O while slowly adding 5 mL H<sub>2</sub>SO<sub>4</sub>. Let mixt. come to room temp. and then add exactly 2 mL sample distillate. Place flask in boiling H<sub>2</sub>O 20 min. Cool under H<sub>2</sub>O to room temp. and dil. to vol. with dil. alcohol (1+3). Shake every few min until soln is clear (10–15 min). (If soln fails to clear, phosphomolybdic acid used to prep. color reagent is unsatisfactory.)

Let stand 0.5 hr and det. A at 725 nm against reagent blank prepd without sample. Det. A' of std soln prepd simultaneously with sample, beginning "Pipet 5 mL color reagent . . ."

Terpin hydrate (g/100 mL elixir) =  $A \times C \times 20/A'$ ; where C = g terpin hydrate/100 mL std soln.

**38.011****Determination of Codeine**

Pipet 5 mL sample into 100 mL beaker, add 0.5 g *p*-toluene-sulfonic acid, and stir with glass rod. Add 6 g diat. earth, mix to fluffy mass, and transfer to tube, 37.002(a), contg plug of glass wool at base. Tamp firmly, and cover with glass wool. Pass H<sub>2</sub>O-satd ether over column and discard ether (Column I).

Mix 2 g diat. earth and 1 mL 1*N* NaHCO<sub>3</sub> (8.4 g/100 mL). Add to second tube (II), tamp, and cover with glass wool. Mount Column I over Column II and place 100 mL vol. flask contg 10 mL MeOH and 4 drops HCl under II. Add in 4 equal portions enough acidified H<sub>2</sub>O-satd CHCl<sub>3</sub> to Column I to fill vol. flask to mark. Completely drain each portion before adding next.

Prep. std codeine soln contg 10 mL std soln, (c), and 2 drops HCl dild to 50 mL with H<sub>2</sub>O-satd CHCl<sub>3</sub>.

Det. A and A' at 287 nm of sample and std solns, resp., against mixt. of 10 mL MeOH and 2 drops HCl dild to 50 mL with H<sub>2</sub>O-satd CHCl<sub>3</sub>.

Codeine.H<sub>2</sub>O, mg/100 mL elixir =  $A \times C \times 20/A'$ , where C = mg codeine.H<sub>2</sub>O in 100 mL std soln.

**Codeine in APC Tablets (4)—Official Final Action**

(Wash all ether with H<sub>2</sub>O and wash 0.1*N* H<sub>2</sub>SO<sub>4</sub> with ether before use in prepn of reagents and in detn.)

**38.012****Reagents**

(a) *Phosphate-citrate buffer*.—pH 5.1. See 38.197 (d).

(b) *Di-(2-ethylhexyl)phosphoric acid (DEHP) soln*.—Prep. daily 1% soln in ether. (Compd available from ICN-K&K Laboratories, Inc. *Caution*: Avoid contact with skin.)

(c) *Codeine std soln*.—120 µg codeine salt/mL 0.1*N* H<sub>2</sub>SO<sub>4</sub>. Prep. fresh daily from phosphate or sulfate salt. Dissolve 60 mg codeine salt in 0.1*N* H<sub>2</sub>SO<sub>4</sub> and dil. to 50 mL. Dil. 10 mL aliquot of this soln to 100 mL with 0.1*N* H<sub>2</sub>SO<sub>4</sub>.

**38.013****Determination**

Grind sample to pass No. 60 sieve.

Pack small glass wool plug in base of 200 × 22 mm id chromatgc tube. Mix 2 g diat. earth, 36.002, and 1 mL pH 5.1 buffer, transfer to tube, and tamp. Accurately weigh ground sample contg 12 mg codeine for 0.5 and 1 grain tablets, 6 mg for 0.25 and 0.125 grain tablets, and 2.5 mg for 1 mg tablets into 100 mL beaker. Add 2.0 mL pH 5.1 buffer and mix to smooth suspension. Add 3 g diat. earth and mix well. Quant. transfer mixt. to tube, above pH 5.1 layer, with aid of scoop-type spatula. Wipe beaker and spatula with glass wool, add to tube, and tamp.

Add 50 mL ether to sample beaker, swirl, and transfer to column. Elute with 4 addnl 50 mL portions ether, letting each portion pass into column before adding next. Rinse tip of column

with 2–3 mL  $\text{CHCl}_3$ . Discard rinse and eluate which contain aspirin, acetophenetidin, and caffeine (APC).

Wash column with 50 mL ether and discard eluate. Rinse tip of column with 2–3 mL  $\text{CHCl}_3$  and dry tip with tissue paper. Place 125 mL separator under column and elute codeine with 50 mL 1% DEHP soln. After soln passes into column, elute with 50 mL ether. Rinse column tip with 5–10 mL ether into separator. Ext with three 10 mL portions 0.1*N*  $\text{H}_2\text{SO}_4$ , collecting exts in vol. flask (100 mL flask for 1 and 0.5 grain codeine, 50 mL flask for 0.25 and 0.125 grain codeine), and dil. to vol. with 0.1*N*  $\text{H}_2\text{SO}_4$ . (For tablets contg 1 mg codeine, use 10, 10, and 4 mL 0.1*N*  $\text{H}_2\text{SO}_4$  and dil. to 25 mL.) Det. *A* of sample and std solns at max., ca 284 nm, against 0.1*N*  $\text{H}_2\text{SO}_4$ . Calc. codeine salt content of tablets.

### 38.014 ★ Codeine, Acetanilid, and Caffeine ★ Official Final Action

See 37.023.

### 38.015 Ethylmorphine (Dionine) in Sirups Official Final Action

See 38.002.

### Hydrocodone (Dihydrocodeinone)—Official Final Action

### 38.016 General Method

See 38.002.

### In Presence of Antihistamines (5)

(Caution: See 51.011, 51.040, and 51.056.)

### 38.017 Apparatus and Reagents

(a) *Chromatographic tubes and tamping rod*.—See 37.002.

(b) *Column I*.—Thoroughly mix 4 g acid-washed diat. earth, 36.002, and 3 mL ca 2*N* HCl. Transfer to tube and tamp to uniform mass, using gentle pressure.

(c) *Column II*.—Mix and tamp layers as in (b). (1) *Lower layer*.—2 g diat. earth and 1 mL 1*N*  $\text{NaHCO}_3$ . (2) *Upper layer*.—4 g diat. earth and 3 mL 6% succinic acid.

(d) *Equilibrated sulfuric acid*.—Thoroughly shake 1*N*  $\text{H}_2\text{SO}_4$  with small vol.  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ .

(e) *Hydrocodone std soln*.—175  $\mu\text{g}$  hydrocodone bitartrate/mL. Dissolve 17.5 mg hydrocodone bitartrate in equilibrated  $\text{H}_2\text{SO}_4$  in 100 mL vol. flask and dil. to vol. with equilibrated  $\text{H}_2\text{SO}_4$ . Shake ca 20 mL std soln with ca 75 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . Det *A'* of aq. phase from 360 to 250 nm.

### 38.018 Determination

Mount Column I directly over Column II. Transfer 10.0 mL sample (or vol. contg ca 3–4 mg hydrocodone bitartrate) to separator. Add 5 mL  $\text{H}_2\text{O}$  and 1 mL ca 1*N* NaOH, and ext with four 30 mL portions of  $\text{CHCl}_3$ . Pass each ext thru columns; let individual exts drain completely into both columns. Wash with 50 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . Discard Column I. Wash Column II with addnl 100 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . Discard eluate.

Add mixt. of 3.5 g diat. earth and 3 mL  $\text{NH}_4\text{OH}$  to Column II, directly onto packing. Tamp. Pass 150 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$  thru column. Evap. eluate to ca 75 mL or until  $\text{NH}_3$  is completely removed (test vapors with moistened indicator paper). Quant. transfer to separator contg 20.0 mL equilibrated  $\text{H}_2\text{SO}_4$  and shake thoroughly. Det. *A* of aq. phase from 360 to 250 nm, using max., ca 282 nm, for calcn.

mg Hydrocodone bitartrate in mL sample taken

$$= (A/A') \times C \times V,$$

where *A* and *A'* refer to sample and std, resp., *C* = mg hydrocodone bitartrate/mL in std, and *V* = vol.  $\text{H}_2\text{SO}_4$  (20 mL).

### 38.019 Morphine in Sirups and Tablets Official Final Action

See 38.002.

### Morphine in Opium and Paregoric (6)—Official Final Action

(Caution: See 51.011, 51.039, 51.040, 51.052, 51.054, and 51.056.)

### 38.020

### Apparatus

(a) *Chromatographic tubes*.—See 37.002.

(b) *Diatomaceous earth*.—See 36.002.

### 38.021

### Reagents

(a) *Triethylamine*.—Purified as in 38.006(a).

(b) *Morphine std soln*.—0.08 mg anhyd. morphine/mL. Accurately weigh morphine base or salt equiv. to 4 mg anhyd. morphine into 50 mL vol. flask. Add 10 mL MeOH, 1 mL HCl, and 1 mL  $\text{Et}_3\text{N}$ , and dil. to vol. with  $\text{CHCl}_3$ . Alternatively, prep. stock soln by dissolving accurately weighed std equiv. to ca 40 mg anhyd. morphine in 0.5 mL  $\text{Et}_3\text{N}$  in 100 mL vol. flask, and dil. to vol. with MeOH. Pipet 10 mL of this stock soln into 50 mL vol. flask, add 1 mL  $\text{Et}_3\text{N}$  and 1 mL HCl, and dil. to vol. with  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ .

(c) *Citrate buffer*.—0.1*M*, pH 4.4. Mix equal vols 0.1*M* Na citrate (2.94 g  $\text{Na}_3\text{C}_6\text{H}_5\text{O}_7 \cdot \text{H}_2\text{O}$ /100 mL) with 0.1*M* citric acid (2.10 g  $\text{H}_3\text{C}_6\text{H}_5\text{O}_7 \cdot \text{H}_2\text{O}$ /100 mL).

### 38.022

### Preparation of Sample

(a) *Opium*.—Accurately weigh ca 2 g opium into 100 mL vol. flask. Add 20 mL dimethyl sulfoxide (DMSO) and heat in beaker of boiling  $\text{H}_2\text{O}$  or in steam bath ca 15 min. Swirl gently to dissolve, keeping opium particles in contact with DMSO and not letting particles remain on walls. Inspect soln carefully. If undissolved material remains, continue heating. Small amt insol. material, such as fine leaf fragments, sandlike particles, and gelatinous particles, may remain undissolved; add more DMSO, if necessary. Cool, add  $\text{H}_2\text{O}$  to ca 90 mL, and mix. Let soln reach room temp., dil. to vol. with  $\text{H}_2\text{O}$ , and mix. (If foaming occurs on mixing, use 1 drop ether or alcohol to dispel foam.)

If sample is in pieces too large to fit in neck of vol. flask, accurately weigh into 250 mL beaker, add 20 mL DMSO, and heat in boiling  $\text{H}_2\text{O}$  or steam bath. Use stirring rod to disperse sample while heating. Decant into 100 mL vol. flask. If undissolved opium remains in beaker, heat with addnl 3 mL portions DMSO as needed until soln is complete as possible (DMSO concn in final soln can vary over wide range without adverse effect.) Dil. to vol. with  $\text{H}_2\text{O}$  as above.

Filter prepd soln thru paper, rejecting first 20 mL filtrate. Use 2 mL aliquot for prepn of Column I.

(b) *Paregoric*.—Evap. 10.0 mL paregoric, contg ca 4 mg morphine, to ca 2 mL on steam bath under stream of air. If evapn continues beyond 2 mL, dil. to 2 mL with  $\text{H}_2\text{O}$ . Cool soln to room temp. and then use for prepn of Column I.

### 38.023

### Preparation of Columns

(a) *Column I*.—(1) *Lower layer*.—Mix 3 g diat. earth and 2 mL citrate buffer; transfer to tube and tamp as in 38.007. (2) *Upper layer*.—Add 0.5 mL citrate buffer to 2.0 mL aliquot of sample ext, 38.022(a) or (b). Add 3 g diat. earth, mix, and transfer to

★ Surplus method—see inside front cover.

tube. Dry-wash beaker with 1 g diat. earth and add to column; tamp and add glass wool pad.

(b) *Column II*.—Mix 3 g diat. earth and 2 mL 1.0M  $K_2HPO_4$  (17.42 g/100 mL); transfer to tube, tamp, and add glass wool pad.

(c) *Column III*.—Mix 3 g diat. earth and 2 mL 0.5M NaOH; transfer to tube, tamp, and add glass wool pad.

**38.024****Determination**

(Use  $H_2O$ -satd solvs thruout. Rinse each column tip with  $CHCl_3$  before discarding columns or changing receivers.)

Pass 100 mL ether, followed by 100 mL  $CHCl_3$ , thru Column I. Discard eluates. Mount Columns II and III in series below Column I. Pass thru columns 5 mL 20% (v/v)  $Et_3N$  in  $CHCl_3$ , followed by four 10 mL portions 1%  $Et_3N$  in  $CHCl_3$ . Let each portion pass thru completely before next addn. Continue elution without delay. Discard Column I, and pass three 5 mL portions 1%  $Et_3N$  in  $CHCl_3$  thru remaining columns. Discard Column II. Wash Column III successively with 10 mL 1%  $Et_3N$  in  $CHCl_3$ , 50 mL  $CHCl_3$ , 2 mL 10% HOAc in  $CHCl_3$ , and 50 mL 1% HOAc in  $CHCl_3$ . Discard all eluates.

Place as receiver under Column III 50 mL vol. flask contg 10 mL MeOH and 1 mL HCl. (Remove metal leashes from vol. flasks to prevent contamination during transfer to cells.) Elute column with 5 mL 20%  $Et_3N$  in  $CHCl_3$ , followed by 33 mL 1%  $Et_3N$  in  $CHCl_3$ . Dil. eluate to vol. with  $CHCl_3$ .

Scan spectrum of eluate and morphine std from 360 to 255 nm, using  $CHCl_3$  as ref. (Film of  $Et_3N \cdot HCl$  may adhere to walls of cells. Rinse cells carefully with  $H_2O$  and alcohol; then wipe clear before scanning.) Correct  $A$  at max., ca 285 nm, by extrapolating baseline from 340 to 310 nm to this wavelength.

mg Anhyd. morphine in aliquot taken =  $(W' \times A/A') \times f$ , where  $W'$  = mg morphine in std soln,  $A$  and  $A'$  = corrected  $A$  of sample and std, resp., and  $f$  = factor to convert wt std to its equiv. in anhyd. morphine (if hydrated morphine or morphine salt is used as std).

**Infrared Method (8)****38.029****Apparatus**

IR spectrophtr for operation in 2–15  $\mu m$  region, with 2 NaCl cells 1.0 mm thick, suitable for  $CS_2$  solns.  $A$  of cells when filled with  $CS_2$  should match to within 0.05; use cell having higher  $A$  for sample soln.

**38.030****Determination**

Transfer enough tablets to yield 5–10 mg atropine to small separator. Dissolve in 5 mL  $H_2O$ , add 1 mL  $NH_4OH$  and 20 mL  $CHCl_3$ , and shake 1 min. Let sep. and filter  $CHCl_3$  layer thru cotton pledget moistened with  $CHCl_3$  into 50 mL g-s flask. Repeat extn with three 10 mL portions  $CHCl_3$ . Evap. combined  $CHCl_3$  exts to dryness on steam bath with aid of air current.

Transfer ca 25 mg atropine, USP, accurately weighed, to 50 mL g-s flask. By pipet, add to sample and std flasks measured vols of  $CS_2$  to produce concns of ca 3 mg/mL. Stopper flasks, mix well, and immediately det.  $A$  of sample and std solns relative to  $CS_2$  at max. of 9.68  $\mu m$ , using baseline between minima at 9.14 and 9.87  $\mu m$ . Calc. atropine sulfate content of sample; atropine  $\times 1.20$  = atropine sulfate.

Record spectra of sample and std solns from 2 to 15  $\mu m$  and compare for identity of sample.

Extn into acid, making alk. and extn into ether, and titrn. See 36.067, 11th ed.

★ Surplus method—see inside front cover.

**38.038 Method II (12)**

(Caution: See 51.011, 51.040, and 51.056.)

(a) *Oily inhalants containing oxazolidines (products of reaction of ephedrine with carbonyl compounds).*—Accurately weigh or otherwise measure sample contg ca 100 mg ephedrine. (With most inhalants, sample size will be ca 10 mL. Altho sample contg as little as 20 mg of the drug may be used if necessary, larger sample should be employed when practicable.) Quant. rinse sample into 125 mL erlenmeyer (lipped flask will facilitate later transfer to separator) with small portions benzene totaling ca 5 mL, add 10 mL H<sub>2</sub>SO<sub>4</sub> (1+35), and boil gently 10 min with frequent agitation and swirling. (Boiling is best done on hot plate, taking care to avoid superheating, bumping, and loss of sample.)

Cool, transfer contents to 125 mL separator, and rinse flask with portions benzene totaling ca 1.5 times vol. sample to remove all oily matter from flask. Shake separator contg the acid and benzene rinsings, drain acid layer into second separator, and vigorously swirl first separator to force down addnl acid and ensure more nearly complete phase sepn. Drain into second separator any acid layer that further seps, and ext benzene-oil phase with the three 5 mL portions H<sub>2</sub>O previously used to rinse flask. Swirl first separator each time after main portion of H<sub>2</sub>O has been drained into second separator. (In transfer of ephedrine from org. solv. to aq. phase, and *vice versa*, shake  $\geq 1$  min and as vigorously as possible without causing emulsions.)

Wash acid soln of ephedrine sulfate with 3 mL CHCl<sub>3</sub> and discard CHCl<sub>3</sub> washings. Make soln alk. to litmus with 20% NaOH soln (ca 2.5 mL); then add 0.5 mL excess and ext ephedrine by shaking *vigorously* with six 15 mL portions CHCl<sub>3</sub>. If >50 mg ephedrine is present, filter exts thru cotton pledget into tared 100 mL beaker previously dried at 110° and cooled in desiccator. After fourth extn, rinse filter funnel and its tip with CHCl<sub>3</sub> (letting rinsings drain into beaker), float 5 drops (0.2 mL) HCl onto surface of combined exts, and evap. on steam bath in air current until beaker can easily accommodate remaining exts. To test for complete extn, shake alk. phase with seventh and eighth 15 mL portions CHCl<sub>3</sub>, filter these thru cotton into small beaker, float 2 drops HCl on surface, and evap. to dryness on steam bath in air current. If *cryst.* residue results, combine it with main exts, using small amt MeOH for transfer, and repeat test if considered necessary.

Continue evapn of main exts to 1 or 2 mL. Then cautiously heat on bath, but without air current, until no HCl odor remains and residue of ephedrine.HCl is apparently dry. Heat beaker 30 min at 110°, cool in desiccator, and weigh. Wt residue  $\times 0.8192$  = wt ephedrine base.

If <50 mg ephedrine is present in sample, carry out extn to completion as described above, and evap. filtered exts in untared beaker until CHCl<sub>3</sub> (but not excess HCl) has been removed. Direct fine stream redistd MeOH around inside of beaker to dissolve ephedrine salt, and immediately repeat process with stream of CHCl<sub>3</sub>. Transfer MeOH-CHCl<sub>3</sub> soln to tared 20 mL beaker, previously dried at 110° and cooled in desiccator, and repeat MeOH and CHCl<sub>3</sub> rinsings until ephedrine.HCl has been quant. transferred. Evap. soln on steam bath, in air current, until the salt begins to crystallize. Continue solv. removal by cautious heating alone, to avoid loss from decrepitation, until residue is apparently dry and there is no odor of HCl. Dry and weigh as above.

(b) *Oily inhalants or petroleum jelly preparations containing free ephedrine only.*—If product is oil, quant. transfer suitable sample, (a), to 125 mL separator with portions benzene totaling ca 1.5 times vol. sample, and ext mixt. with 5 mL H<sub>2</sub>SO<sub>4</sub> (1+16) and then with four 5 mL portions H<sub>2</sub>O, swirling separator each time as in (a), and continue assay as in (a), par. 3, beginning

"Wash acid soln of ephedrine sulfate . . ." If product is petroleum jelly prepn, dissolve sample in enough benzene to obtain soln of suitable fluidity (30 mL should be enough for 10 g sample) and proceed as for oily inhalants.

**38.039 ★ Ephedrine in Water-Soluble Jellies, ★  
Sirups, and Solutions of Ephedrine Salts  
Official Final Action**

Extn with ether from alk. soln, extn by acid, re-extn by CHCl<sub>3</sub> from alk. soln, and gravimetric detn by 38.038. See 38.039, 12th ed.

**Ephedrine in Tablets and Capsules—Official Final Action**

**38.040 Method I**

See 38.002.

**38.041 ★ Method II (12) ★**

Extn with ether from Na<sub>2</sub>CO<sub>3</sub> soln. See 38.041, 12th ed.

**Ergotamine (13)—Official Final Action**

(Applicable in presence of caffeine, acetophenetidin, phenobarbital, and belladonna alkaloids)

**38.042**

**Reagents**

(a) *Tartaric acid soln.*—1%. Dissolve 10 g tartaric acid in H<sub>2</sub>O and dil. to 1 L.

(b) *Alcoholic tartaric acid soln.*—Mix equal vols tartaric acid soln, (a), with alcohol. Prep. fresh daily.

(c) *Sodium bicarbonate soln.*—10%. Dissolve 100 g NaHCO<sub>3</sub> in H<sub>2</sub>O and dil. to 1 L.

(d) *Citric acid soln.*—(1+1). Mix equal wts of citric acid and H<sub>2</sub>O.

(e) *Alum soln.*—0.25M. Dissolve 12 g KAl(SO<sub>4</sub>)<sub>2</sub> · 12H<sub>2</sub>O in H<sub>2</sub>O and dil. to 1 L. pH should be 3.5  $\pm$  0.2.

(f) *Color reagent.*—Dissolve 1.25 g *p*-dimethylaminobenzaldehyde in cooled mixt. of 650 mL H<sub>2</sub>SO<sub>4</sub> and 350 mL H<sub>2</sub>O. Add 0.5 mL 9% FeCl<sub>3</sub> soln.

(g) *Diatomaceous earth.*—See 36.002.

(h) *Ergotamine tartrate std soln.*—50  $\mu$ g/mL. Dissolve 25 mg ergotamine tartrate, USP, in enough tartaric acid soln, (a), to make 500 mL.

**38.043**

**Preparation of Chromatographic Column**

*Chromatographic tube.*—Prep. chromatgc tube as in 37.002(a). Fit with packing rod, 37.002(b). Place small wad of glass wool in bottom of tube.

*Ergotamine-retaining layer.*—Add ca 4 g diat. earth to 3 mL citric acid soln in beaker. Mix thoroly with scoop-shaped spatula until mixt. appears fluffy and uniform, and transfer to chromatgc tube. Tap side of tube gently to settle mixt. Press down firmly with packing rod.

*Ergonovine-retaining layer.*—Add ca 2 g diat. earth to 2 mL alum soln, mix, and transfer to tube on top of citric acid layer. Press down firmly and evenly.

*Water layer.*—Add ca 2 g diat. earth to 2 mL H<sub>2</sub>O, mix, and transfer to tube on top of alum layer. Press down firmly and evenly and top with pad of glass wool.

**38.044**

**Preparation of Sample**

(a) *Tablets.*—Det. av. wt and reduce to fine powder. Accurately weigh portion contg ca 2.5 mg ergotamine tartrate into beaker.

★ Surplus method—see inside front cover.

Mix thoroly with 5 mL 1% tartaric acid soln and let stand 30 min. Add 5 mL  $\text{CHCl}_3$  and 1 mL 10%  $\text{NaHCO}_3$  soln, and mix. (Aq. phase must be alk.) Add ca 7 g diat. earth and stir thoroly until mass appears uniform and does not stick to beaker. (It may be necessary to wash down sides of beaker with small amts of  $\text{CHCl}_3$ .) Add and mix more diat. earth as may be necessary to make mixt. workable. Quant. transfer mixt. to another chromatgc tube fitted with glass wool plug, in several portions, pressing down firmly with packing rod. Wash packing rod, spatula, and sides of beaker with small amt (ca 5 mL) of  $\text{CHCl}_3$ . Add enough diat. earth to make mixt. workable. Scrub sides of beaker and add mixt. to tube. Again rinse rod, spatula, and beaker with  $\text{CHCl}_3$  and pour wash onto column.

(b) *Suppositories*.—Place suppositories contg 3–5 mg ergotamine tartrate in 125 mL separator. Add 10 mL 0.2N  $\text{H}_2\text{SO}_4$  and 75 mL ether. Shake until sample dissolves and then 1 min more. Drain acid layer into second separator. Complete extn with three 10 mL portions acid. Discard ether layer. Combine exts and make alk. with  $\text{NH}_4\text{OH}$ . Promptly ext alkaloids with four 10 mL portions  $\text{CHCl}_3$ . Pass each  $\text{CHCl}_3$  ext directly onto prepd column, **38.043**. Let column drain completely between addn of successive exts. Proceed as in **38.045**, second par.

**38.045****Separation of Ergotamine**

Place tube contg sample so that effluent will flow directly onto water layer of second column. Add 50 mL  $\text{H}_2\text{O}$ -satd ether to top column and receive eluate from bottom column in 250 mL erlenmeyer. Follow with 50 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$ . (Since effluent may flow faster thru sample column than thru second column, do not add too much  $\text{CHCl}_3$  at a time.) Rinse tip of sample column with  $\text{CHCl}_3$  from wash bottle and discard sample column.

Let column drain completely and then rinse down sides with small amt of  $\text{CHCl}_3$ . Pass thru addnl 25 mL  $\text{H}_2\text{O}$ -satd  $\text{CHCl}_3$  into same flask and rinse tip of column with alcohol. Discard effluent if ergotamine was properly retained. (See Note.)

Inspect column for proper retention of ergotamine and for presence of  $\text{H}_2\text{O}$ -sol. alkaloids by holding column under UV light very briefly. (Caution: See **51.016**.) Blue fluorescent band must not be at bottom of column. (See Note.) Extrude column into 400 mL beaker. Rinse tube with  $\text{H}_2\text{O}$ . Add 8 g  $\text{NaHCO}_3$  and ca 25 mL  $\text{H}_2\text{O}$  to form aq. liq. layer. Break up column with spatula and mix. Wash mixt. with  $\text{H}_2\text{O}$  from wash bottle into 250 mL separator. Add 10 mL  $\text{CHCl}_3$  and shake. Check aq. layer to assure that it is alk. Be sure that layers are well sepd. It may be necessary to break  $\text{CHCl}_3$  bubbles with wire. Drain  $\text{CHCl}_3$  layer thru glass wool filter into 100 mL vol. flask. Ext aq. layer with four 10 mL portions  $\text{CHCl}_3$  and filter solv. layers into the 100 mL vol. flask. Dil. to vol. with  $\text{CHCl}_3$ , and mix.

**38.046****Determination**

Evap. 10 mL aliquot  $\text{CHCl}_3$  soln in 50 mL erlenmeyer to dryness with air current. Do not heat. (Ergotamine is easily decomposed. If assay cannot be completed in 1 day, dried residue after evapn of  $\text{CHCl}_3$  may be stored in refrigerator overnight.) Dissolve residue, equiv. to 0.25 mg ergotamine tartrate, in 5.0 mL alc. tartrate soln. Pipet 5.0 mL std soln into 50 mL erlenmeyer. Add, to each, 10 mL color reagent dropwise while swirling continuously in ice- $\text{H}_2\text{O}$  bath. After 30, but <60 min, det. A of sample and of std, A', at 550 nm against blank prepd by mixing 5 mL  $\text{H}_2\text{O}$  and 10 mL reagent.

mg Ergotamine tartrate in sample weighed =  $(A/A') \times 2.5$ .

Note: Ergot alkaloids fluoresce bright blue when exposed to UV light at ca 360 nm. If fluorescent band has reached bottom of trap layer, sample must be discarded. If desired, sample can be salvaged by combining column and effluent, shaking with

$\text{CHCl}_3$ , and passing thru another acid trap. Use of eluant which is not  $\text{H}_2\text{O}$ -satd will cause loss of ergotamine from column. Blue fluorescent ring at top of alum layer indicates presence of  $\text{H}_2\text{O}$ -sol. ergot alkaloids. If detn of  $\text{H}_2\text{O}$ -sol. alkaloid content is desired, repeat detn on new portion of sample, changing citric acid trap to one prepd by mixing 3 g diat. earth with 3 mL alum soln. Cover alum layer with mixt. of 2 g diat. earth and 2 mL  $\text{H}_2\text{O}$ .

**Paper Chromatographic Identification (14)****Official Final Action****38.047****Reagents**

(a) *Mobile solvent*.—Dissolve 7.1 g Na citrate in  $\text{H}_2\text{O}$  and dil. to 100 mL. Adjust pH to ca 4.7 with 2N HCl and transfer to separator. Add 70 mL formamide and 9 mL dimethylphthalate. Shake vigorously, let sep., and drain and discard lower layer. Adjust to pH 5.2 with 2N HCl or NaOH.

(b) *Immobil solvent*.—Dimethylphthalate- $\text{CHCl}_3$  (1+9). Prep. immediately before use.

(c) *Ergotamine std solns*.—Accurately weigh 10 mg ergotamine tartrate, USP, into small separator contg 5 mL 1% tartaric acid soln and mix gently. Make alk. with few drops 10%  $\text{NaHCO}_3$  soln, add 2.0 mL  $\text{CHCl}_3$ , and shake vigorously. Draw off  $\text{CHCl}_3$  layer (std soln 1). Dil. 1.0 mL std soln 1 to 25 mL with  $\text{CHCl}_3$  (std soln 2).

**38.048****Identification**

For details of app. and technic see **29.007** and **29.028**. Blotter paper liners must be used in tank and tank must be sealed.

Equilibrate mobile solv. in sealed tank  $\geq 3$  hr with liners dipping into solv. Just before use, quickly dip marked  $8 \times 8$ " paper once in freshly prepd immobile solv. and let dry 15 min.

Prep. soln of ergotamine in  $\text{CHCl}_3$ , as in **38.045**, contg 2.5 mg/0.5 mL (remainder of  $\text{CHCl}_3$  soln from assay may be evapd to this concn). Spot 10  $\mu\text{L}$  each of sample and std solns on paper and let solv. evap. Place paper in tank, seal tank, and let chromatogram develop until solv. front is ca 2.5 cm from top (ca 3 hr). Let paper dry overnight in hood and examine under UV light. There should be one yellow primary spot (and there may be a "tail," probably as result of ergotamine changing to ergotamine during developing) corresponding to 50  $\mu\text{g}$  ergotamine spot (std 1) in position and intensity. If any other spot is more intense than that of std 2,  $>2 \mu\text{g}$  other ergot alkaloids, expressed as ergotamine tartrate, are present.
